But the most important physiological consideration which should prevent the practitioner being too liberal in his allowance of fluid nourishment is the fact that a certain *bulk* in the food is as necessary for healthy digestion, as the presence of the nutrient principle itself. The Kamschatdales, observes Dr. Carpenter, are in the habit of mixing earth or saw-dust with the train-oil on which alone they frequently live. The Veddahs, or wild hunters of Ceylon, on the same principle, mingle the powdered fibres of soft and decayed wood with the honey on which they feed when meat is not to be had, and on one of them being asked the reason of the practice, he replied, "I cannot tell you, but I know that the belly must be filled." It is further shown by Dr. Beaumont that soups and fluid diet are not more readily chymified than solid aliment, and are not alone fit for the support of the system. The physiologist we have quoted does not enter into the reasons why a certain bulk or consistency in food should be necessary to its thorough digestion, but the fact is not difficult to account for, and its explanation furnishes another argument in favour of prescribing in many cases solid in preference to fluid nourishment. It is well known that the secretion of a due amount of gastric juice is a *sine quâ non* of healthy digestion, and that this condition is itself very much dependent upon the stimulus which the presence of food in the stomach gives to the nerves which supply that organ. This secretion is partly in fact a reflex act. Now, it is only reasonable to suppose that the irritation excited by the presence of food in the stomach will not be so great when the food is in a liquid state, as it would be were it administered in a solid form, and consequently, while the fluid food may contain quite as much albuminous matter, and require for its digestion quite as much gastric juice as the solid food, the quantity of this juice may, from the stimulus to secretion being less, fall short of what is necessary to perfect digestion. Besides, it cannot be denied that those churning movements of the stomach which take place when solid nutriment is taken, have a very important share in the digestive operation, that the effect of these peristaltic movements is to bring every portion of the food into contact with the secretions of the stomach, and even to promote the flow of those secretions, and that they chiefly or only take place when the food is of sufficient bulk or consistence as to form a sort of *point d'appui* for the coats of the stomach to work upon. At all events, whatever advantages arise from these churning movements of the stomach, it is evident that they will not obtain to the same extent when the contents of that organ are of a fluid nature, and when, in consequence of the rapid absorption of the fluid, the bulk of the residue is insufficient to excite the movements above-mentioned. These considerations, therefore, are enough to account for the instinctive desire in man to fill the stomach with food of a more or less bulky nature, and for the fact that a certain consistency in the food is an essential condition of good digestion. But there are still two or three other

points to which we would draw attention. There is the great fact that Nature rarely or ever supplies the food of either animals or plants in a concentrated form. She leaves it to the digestive or absorbent organs of the plant or animal to extract out of various heterogeneous and bulky substances such aliment as is best fitted for their healthy life and growth; and it is doubtful whether a principle which, in the case of health, obtains so universally in nature, should be wholly ignored in the case of disease. Then it is questionable whether the rapidity with which the more fluid kinds of food are absorbed by the veins of the stomach does not hinder the albuminous or gelatinous materials of which they are so largely composed being submitted to that action of the gastric juice, in virtue of which these subtances are reduced or lowered in their chemical composition, and are converted into a low form of albumen termed *albuminose*, or *peptone*. That this conversion of albumen into albuminose is essential to the due assimilation of the food is shown by the experiments of Bernard, who found that albumen dissolved in water and injected into the jugular veins was always secreted in the urine; but if, previous to injection, it was mixed with gastric juice no trace of it could be detected in the urine. It is, therefore, not unreasonable to assume that when large quantities of fluid nourishment are administered much of its albuminous constituents escape this action of the gastric juice, and, although the liver, which also plays an important part in rendering albumen assimilable, may partly fulfil a function which the stomach has been unable to perform, it is only at the risk of the functions of that organ being overtaxed, and the albuminose not being properly formed and assimilated.

Such are some physiological reasons why the medical practitioner should seldom administer large quantities of fluid nourishment when more solid food can be tolerated, and we regret that want of space forbids our going further into a subject which does not seem to have received so much consideration as it deserves.

THE OVERWORK OF EDUCATION.

The latest office requirements of the London School Board, backed up by the Educational Department of the Privy Council, appear, if we may judge by the numerous letters of complaint in the daily papers, to have been the last straw that has broken the backs of their teachers. However indisposed we may feel to assist in these complaints, it will not be denied that the amount of extra work demanded of this body of public servants is not only of a most harassing nature, but as unnecessarily tending to increase expenditure, which must eventually fall upon the already overburdened taxpayer. From a medical point of view we may say that the fussy kind of clerical work thrust upon teachers is calculated to impair health and destroy the mental faculties of those who are called upon to render accounts without number. It has frequently of late been urged upon the notice of the School Board that health and education do not go as they should hand-in-hand together. The more serious blot on our educational system is, however, partially due to the fact that the building up of the brain and preserving the body in health and vigour is no part of anybody's business; far too little consideration is bestowed upon the physical condition of the young; how surely the work of education may proceed is quite enough for managers of School Boards. Dr. Richardson quite recently endeavoured to place the neglect of health prominently before those whom it may concern. He observed: "We think it cruel to put a young horse into harness and make it work whilst it is growing, but in the case of a young person, we think it a mark of genius and ambition to be commended." He might have put in a plea on another point of scarcely less moment, and thereby have made it more apparent, that the young of the human species are placed at a far greater disadvantage as compared with that of the horse. In the case of the horse, the greatest possible care is bestowed on breeding, and to ensure the survival of the fittest care is taken to breed only from the healthiest stock, so that neither hereditary diseases nor vices may be transmitted. On the other hand, a large portion of our children are the offspring of diseased and vicious parents, are born to all the ills that flesh and blood are heir to. Nevertheless, it is attempted to enforce the same educational standard on all children alike, upon the weak and sickly as upon the healthy and robust. So little attention is given to this important subject that no one conversant with our system can be surprised that, as a rule, the weakly and sickly go to the wall, whilst the healthier, and, possibly the sharper-witted, are made much of, crammed to do show work because it pays. In truth—the teacher is tempted to neglect his duller and more troublesome scholars, those who really need the most care and supervision, and to devote himself chiefly to those who will most easily earn the "grants"—but in the end both pupil and teacher pay the penalty in loss of physical and mental power.

In the particular instance of the teacher the first requisite of success "is to be a good animal." A moderate share of success in any walk of life, is hardly to be achieved without an average amount of good health; and the question is, will either the pupil or the teacher under the present system of education become a good animal and achieve a solid and lasting success? We will endeavour briefly to answer this question from the teacher point of view. We gather the work of the teacher under the new regulations appears to be of a dual nature, combining that of the pupil and teacher in one person. Teaching and learning is carried on concurrently from morning to night, from week's end to week's end. Work begins at nine in the morning, and continues until noon, when a brief interval is allowed for a hasty meal (taken generally in bad air); at one or two it recommences, and it is not suspended before four or five o'clock, when another short interval of rest occurs; after which, the whole evening is devoted to the preparation of work for the next day. A further serious demand is made upon the teacher, encroaching on hours that should be given to rest and sleep; for certificates of the attendances of scholars must be prepared and ready for the board of guardians, as well as duplicate registers for school-board visitors; together with quarterly returns of averages to the school board, making up of childrens' books, adding to each a copy of certificate of birth or registration in case of new comers, and further certificates of general

proficiency on leaving the school. To all this must be added a particular kind of information demanded by school-board visitors as to children playing truant, leaving school, irregular attendances, circumstances of parents, &c., together with a full report of all children above five years of age who are attending or have attended school, and the sum total of attendances of all the pupils during the year. If this round of work is not designed to break down the brain of the strongest human animal, it is certainly a test of the power of endurance of which the strongest amongst us may justly complain, and against the strict enforcement of which we would venture to protest.

THE COMING MEDICAL REFORM.

It may be easily conceived that the profession has been anxious to learn the nature of the Bill which the Duke of Richmond has notified his intention of laying before the House. It was evident from the speech of the noble Lord that the measure would be a much larger reform than had been supposed, and that the Government fully intended to deal with medical reform on its own responsibility, and without much regard to the opinions of the profession. During the past week the greatest reserve has been observed as to the nature of the measure, and its provisions have only been laid before a few individuals, who were given to understand privacy was expected. Nevertheless, it is positively stated in London that the Government has decided upon enforcing in Ireland and Scotland a conjoint examination similar to that now in course of consummation in England. This will, if true, be serious news for the Queen's University and the Scotch colleges, who have to anticipate being dragged up to the level of the English co-operating bodies, and whose diplomas will thus lose the attractions of cheapness and brevity of curriculum. On the other hand, it will be equally weighty tidings for the Dublin lecturers, because the assimilation of curricula will inevitably cut down by one-fourth the number of lecture certificates required for Irish diplomas. The Medical Council has not been asked its opinion upon the movement, but it has already expressed and reiterated its opinion in favour of uniformity of conjoint examination throughout the kingdom, and in favour of a greatly curtailed curriculum of lectures; and it must, therefore, approve of the measure when the time comes for it to give utterance to its views. It is to be presumed that the Bill will legalise foreign degrees, as was promised last year when the question was mooted in the French Chamber, and this, of itself, is a move in which professional interests are deeply involved. Lastly, it may, perhaps, contain a clause to establish a registration of dental practitioners—the purpose which Sir John Lubbock is endeavouring to obtain by means so objectionable. We shall, of course, inform our readers of the nature of the Government Bill at the earliest moment that it can be obtained.

In St. Petersburgh, according to the last weekly return, the death-rate reached the extraordinary figure of 62 per 1,000 of the population, the highest rate ever known. This is a higher rate, by 100 per cent., than any other European city, Rome, Munich, and Naples excepted, which stand respectively at 42, 43, and 45 per 1,000.

Notes on Current Topics.

Sensational Therapeutics.

According to a statement in the *Gaz. des Hôpitaux*, No. 92, 1877, we are seriously asked to believe that Dr. Liron has treated successfully three cases of acute articular rheumatism by the subcutaneous injection of about 20 drops of cold water in the vicinity of the affected joint. It is also stated that the plan was originally suggested by Potain, and more recently recommended by Dieulafoy. Such is the astounding announcement which is made in a respectable foreign journal, and which has also found its way into one of our own journals especially devoted to the subject of therapeutics. The credulity of the public is a frequent subject of conversation among those who are not inclined to believe all they hear, but we often think that scientific credulities, and especially the credulity of medical men, sometimes equal anything that happens in connection with fortune-telling, spiritualism, and other delusions. To suppose for one moment that the injection of a few drops of cold water will cure a severe disease, which unquestionably depends upon a well-marked disordered condition of the blood, seems to us a belief that could only arise from the grossest ignorance or simplicity. There are a few functional nervous disorders in which a slight impression made upon the peripheral nerves, and upon the imagination of the patient, may arrest the symptoms to which those disorders give rise. But acute articular rheumatism is a disease of quite another kind, and is no more likely to be cured by injecting beneath the skin a few drops of cold water, than by the external application of a piece of metal, or the employment of those charms which the savage believes to be so effective in curing all kinds of distempers. It is impossible to think of any way—of any *modus operandi*—in virtue of which such a plan could possibly cure such a disease as we know acute rheumatism to be. There is no imaginable effect of this treatment that can either counteract, or eliminate from the system, that morbid condition of the blood on which this disease undoubtedly depends; and a very large number of alleged cures would have to be brought forward, before we could think such treatment deserving of the least consideration.

And let us ask our readers—let us ask the profession—if this is the way in which we hope to advance the science of therapeutics? Over and over again we read in the columns of the medical journals statements which, although not quite so wild and fanciful as that to which we are now drawing attention, do not fall far short of it, with respect either to their credibility or the confidence with which they are made. A certain remedy, potent or not, it does not much matter, is tried in a few cases of some kind of disease, and because the case terminates favourably, it is concluded that its successful issue is to be attributed to the effects of the remedy. When people are to be found who will put faith in the therapeutic efficacy of a few drops of cold water, we need scarcely wonder that some new petty remedy is constantly cropping up, only to fall into disuse, and to be succeeded by some other remedy equally worthless; so that we may still say of practical therapeutics what Bacon said of medicine three hundred years

ago, namely, that "it is a science which hath been more professed than laboured, and yet more laboured than advanced; the labour having been, in my judgment, rather in a circle than in progression."

Medical Prescriptions.

THE *Monthly Magazine of Pharmacy*, &c., very properly draws attention to the careless manner in which medicines are often prescribed. The carelessness which is constantly evinced in this department of medical practice is, we are told, becoming greater and greater every year. Prescriptions are usually written in Latin, not in good, plain, elegant Latin, but in a kind of abbreviated dog Latin, which in nine cases out of ten would be perfectly unintelligible to an inhabitant of ancient Rome. Then the great liability of a bad writer to mislead the dispenser, is to be taken into consideration. A few flourishes of the pen in the hand of a nervous man may easily convert bicarbonate of potash into bromide of potassium, or dilute hydrochloric acid into hydrocyanic acid. The use of contractions is especially dangerous; for instance, we have before us a case in which a bad abbreviation employed for hydrate of chloral, was read by an apothecary's assistant to mean calomel (chlor. hydr.), and the results may be easily imagined.

Our contemporary is quite justified in making these complaints, and we quite agree with him that if the medical practitioner could be induced to write his prescriptions with greater care and preciseness, a vast amount of unnecessary trouble and anxiety would be taken from the shoulders of the dispenser. The chemist should not have to "weed out errors in physicians' prescriptions, nor to feel a twinge of conscience every time he dispenses a medicine, that he may possibly have done something wrong, and by no fault of his own." There appears to us two great reasons why we should be more than ever careful in this matter of writing prescriptions. For, in the first place, the handwriting of medical men is, as a rule, notoriously bad; and, in the second place, the habit of writing prescriptions, instead of dispensing their own medicines, is now extensively adopted by general practitioners. The remark, however, of our contemporary with regard to writing prescriptions in Latin, is only applicable to the names of the drugs prescribed, inasmuch as both the physician and the general practitioner are usually in the habit of writing the directions in English. As regards poisonous or very potent remedies, it would be well if the prescriber were to always write the name of the drug in full, instead of abbreviating it, as is his usual practice, for in that case no harm could be done, or no more than the substitution of one innoccuous drug for another.

Increase of Lunacy in Paris.

A CORRESPONDENT of one of the daily papers says there is at present a marked increase in the number of persons attacked with mental diseases in Paris. All the lunatic asylums are crowded, and new cases are brought before the medical profession every day. It is remarkable that almost all of the unfortunate patients speak of the war in the East, or suppose themselves to be Victor Emmanuel or the Pope. The Eastern question, however, can have nothing to do with the increase of lunacy among the population of Paris, considering how very remotely that question affects the interests of the French nation. The fact is, that the greater prevalence of insanity is not confined to Paris, but is also remarkable in other great centres of civilisation—in the United States, in this country, and elsewhere. It is to be attributed to causes which are, for the most part, connected with modern habits and modern modes of life; but the exact nature of these causes it is not so easy to determine. But of one fact we can be certain, namely, that many of them are avoidable, and therefore, it would be well if the attention of alienist physicians was particularly directed to those causes of insanity which are more especially connected with the social institutions and habits of the present day. The increase of lunacy among a people reflects no credit, either upon the people themselves or their governors; and when this disease has been shown to be unusually prevalent, it is the duty of the State to inquire into the causes thoroughly, and, as far as possible, to put a stop to them.

The Effect of the Contagious Diseases Act on the Health of the Army.

IT appears from the Report of the Army Medical Department, just issued, that the ratio per 1,000 admitted for primary venereal sores into fourteen stations under the Act was only 33, while in the fourteen stations *not* under the Act, the ratio was 82; and for gonorrhœa, while the ratio was but 68 in the protected districts, it was 89 in the unprotected districts.

As usual, venereal disease has mostly contributed to the general amount of sickness; but "it is satisfactory to be again able to report most favourably upon the salutary effect of the Contagious Disaases Acts at Colchester, the only station in the Eastern district where it is in operation." Surgeon-General Watt gives similar testimony with regard to the South Eastern District. "I must," he says, "reiterate my opinion that these enactments exercise a salutary influence on the health of the soldier, a view in which I am supported by nearly all the medical officers in command." In some of the protected places, however, such as at Chatham and Woolwich, venereal diseases have largely prevailed, owing to many of the men having come from unprotected places, and to some going away for a short leave to London and elsewhere. Thus at the latter district we are told that the admissions for venereal disease continued to cause a great deal of inefficiency, being equal to about one-sixth of the entire admissions. At Woolwich, however, great difficulties exist against the better prevention of this evil. Not until all the stations are under the influence of the Contagious Diseases Act, can we expect the beneficial effects of the Act in the protected districts to be so marked as they should be.

On Lying-In after Delivery.

THE *London Medical Record* draws the attention of its readers to an article in the Proceedings of the Medical Society of the County of Kings, 1877, by Dr. Garrigues, on the question, "How Long Ought Women to Stay in Bed After Delivery?" Dr. Goodell was of opinion that women should be encouraged to get up early because

1. Labour is a physiological process, and should not be made to wear the livery of disease. 2. The upright position excites the uterus to contract, and lessens the amount and direction of the lochia. 3. Uterine diseases are hardly known among nations whose women early leave their beds. 4. According to his experience, convalescence is rendered far more prompt and sure. On the other hand, Dr. Garrigues combats these views, and says that the present condition of women is not one of a normal physiological nature, and that flexions may be produced by the flaccidity and weight of the womb before the contractions impede it. Considering also the state of the internal parts after parturition, and the transformation, absorption, and restitution, that have to take place, he is in favour of prolonged rest in a horizontal posture.

We are, however, strongly of opinion that there is a good deal of truth in Dr. Goodell's view on the subject, and certainly it would be worth while to put the question to the test of experiment. The system of rest has been, in these cases, so long and universally adopted in all civilised nations, that it is impossible to say what would be the result of giving the plan advocated by Dr. Goodell a fair and extended trial. With regard to the risk of this method producing flexions of the uterus, we cannot, at all events, say that the present method prevents them, for according to all we hear and see, flexions of the womb appear to be more prevalent at the present day than at any previous period. There may also be much truth in the opinion of Dr. Goodell, that the upright position excites the uterus to contract, and lessens the amount of lochia. His observation reminds us of the many times we have seen the loss of blood in certain forms of uterine hæmorrhage rather lessened than aggravated, by the patient being up, or even gently walking about, instead of being kept to the warm bed in a horizontal posture. In conclusion, we should say that Dr. Goodell's plan deserves further attention from obstetricians, particularly as in all cases in which this plan may be tried, the quantity and quality of the lochia, and other symptoms, would show whether it was doing any harm, and the propriety or not of continuing it.

Siegen on the Utility of Alcohol in Disease.

As our readers are aware, we have taken some interest in the alcohol question, and, therefore, we cannot help drawing their attention to the opinion of an eminent German authority on the subject, and for our knowledge of which we are indebted to the columns of the *London Medical Record*. Dr. Siegen remarks (*Deutsche Med. Wochenschrift*, Dec. 8) that the use of alcohol is still dreaded by many in febrile and other affections as adding fuel to the fire; but he cites several cases showing its utility. One was a case of phthisis, in which the appetite and weight increased, the temperature was much diminished, and a general improvement took place in all the symptoms, under a liberal allowance of beer amounting to about 3 1-5th ounces of alcohol per day. A second case was one of circumscribed peritonitis, following typlitis. There was marked collapse, everything was vomited except wine, and neither morphia nor chloral procured relief. The temperature stood at 40·6 C. (105 F.) Heavy Rhine wine was ordered in large quantities, after which the patient slept for the first time during eight days, and the temperature sank to 38·6 C. (101·48 F.) In three hours alcohol had been taken to the extent of about 5 ozs. For fourteen days nothing but wine was taken, and the patient made a perfect recovery. Other cases are also referred to, in all of which rapid convalescence resulted. Dr. Siegen specially recommends the use of alcohol in phthisis and hæmoptysis. Moreover, in the diarrhœa of children with vomiting, it is sufficient to sustain the system to the exclusion of all other nourishment, and without being vomited, until the inflamed gastro-intestinal mucous membrane recovers its normal function.

Ophthalmic Nostrums.

Amongst an interesting pharmacopœia of quack medicines now in course of publication in the *Chemist and Druggist* we find the following:—

Eye Balsam (Müller, Berlin):—Red oxide of mercury, 5 parts; opium, 3; unsalted butter, 100.

Eye Essence (Romershausen).—A tincture prepared from fennel seeds and fresh young fennel. 250 grammes. 3s.—*Hager.*

Vegetable Eye Balsam (Reichel):—Opium, 5 parts; oxide of mercury, 5; camphor, 2; wax cerate, 52. Four grains in a piece of calf's bladder. 3s.—*Hager.*

Hoffman's Ophthalmic Water (Cologne).—A solution of one pint of sulphate of iron in 50 parts of rose water.

Eye Powder (Laeyson, Paris), also known as Odorous Powder.—For the strengthening, restoration, and preservation of the sight. A powder composed of burnt chalk, 100 parts; ammonia, 50; charcoal, 6; oxide of iron, 2; cinnamon bark, 2.

Eye Salt.—Powdered alum.—*G. Graefe.*

Eye Water (Biederman).—2 grammes sulphate of zinc in 60 grammes distilled water, with a little infusion of cloves.

Eye Water (Brun) is a solution of 4 parts of aloes in 32 parts of white wine, with 32 parts of rose water, and 1½ part of tincture of saffron.

Eye Water (Chantomelanus) "makes spectacles superfluous." A turbid yellow-brownish liquid, consisting of a weak extract of lavender flowers in diluted spirit, in which some oil of lavender has also been dissolved.

De Graefe's Eye Water (L. Roth), sulphate of zinc, 1·5 grammes; fennel water, 100; slightly coloured with fennel seed tincture. 3s.—*Schädler.*

Eye Water (Hette).—A solution of etherial oils of lavender, bergamot, rosemary, and tincture of opium in spirits of wine, 50 per cent.

Eye Water (Bernhard Kraft, Calbe) for acute inflammation of the eyes and for strengthening the sight. Seven grammes of an impure muddy sediment-leaving spring water containing half a gramme of native sulphate of zinc containing iron.

Eye Water (Stroinski).—One part of sulphate of zinc dissolved in 500 parts of common river water.

Dr. White's Eye Water.—Four cloves, a piece of cinnamon the size of a large pea, two teaspoonfuls of rose water, 1 drop of vinegar, 10 drops of arnica tincture. Digest for an hour and filter. Dissolve in the filtrate some white vitriol of the size of a pea.—*Hager.*

Russian Treatment of English Doctors.

Considering the animosity that exists at the present time between the Russians and any Englishmen who are serving in the Eastern war, we must not be surprised if English doctors come in for their share of ill-treatment at the hands of a nation that can scarcely be said to be characterised by the civilisation and chivalry of Western Europe. A few days ago Mr. Cowen asked, in the House

of Commons, the Under Secretary of State for Foreign Affairs whether there was any objection to publishing the statement supplied to the English Consul at Adrianople concerning the treatment endured by Dr. Armand Leslie and Dr. Neville, of the National Aid Society; of Dr. Kirkpatrick, of the Red Crescent Society; and of Mr. Bell, the correspondent of the *Illustrated London News*, who fell into the hands of the Russians on January 1, and were kept prisoners by them for five weeks.

Mr. Bourke said, with regard to the first question of the hon. member, there will be no objection to lay the statement to which he alludes before Parliament, as well as other documents relative to that statement.

It must not, however be expected that these medical officers will receive any substantial reparation for the ill-treatment to which they have been subjected. Nor is it likely that the Government will let the misfortunes of these officers add to the difficulties under which they are labouring in their endeavour to settle the Eastern question. Some apology from the Russian authorities is perhaps all the English doctors will get, and, under the circumstances, it will be advisable for them to be satisfied with this scanty acknowledgment of the wrongs they had to endure.

Infraction of the Lunacy Act.

Dr. Samuel Turrell, of Windsor, was last week indicted for taking under his care an insane lady, named Pennell, daughter of Sir Henry Pennell, neglecting to procure the necessary order, and to inform the Commissioners in Lunacy that the lady was insane. The neighbours' alarm at the conduct of Miss Pennell came to the knowledge of the Lunacy Commissioners, and Dr. Bucknill went to see the patient in pursuance of an order from the Lord Chancellor. He found her in charge of a nurse. She was in bed in a small back room upstairs. Her body was well nourished and cleanly; but Dr. Bucknill did not think it good treatment to keep her confined in such a room, nor did he think such treatment would have been sanctioned by the Commissioners. In 1873 Sir Henry Pennell consulted Sir William Gull and other eminent men as to Miss Pennell's condition, and when he placed her under Dr. Turrell's care he informed the doctor that she was only suffering from nervous debility, being quite of opinion that she was not insane. He said he considered that Dr. Turrell had been strictly honourable in his conduct. The only question left for the jury to decide was whether or not Dr. Turrell knew Miss Pennell to be insane at the time he received her. After being locked up from seven till nine o'clock the jury announced that they could not agree. They were accordingly discharged, and a fresh jury was empanelled on Saturday, but the second trial was postponed till the Summer Assizes.

The Scientific Department of the Paris Exhibition.

It has been arranged that each Government department of France shall show the way in which its scientific work is done. The three new Government observatories in Paris will exhibit either results or methods. There will be a complete collection illustrating the various scientific missions which France has undertaken during the present century and all the publications, scientific, historic, and artistic, which have been published by the State will be there for all the world to see.

Not only, therefore, will there be a true Loan Collection of Scientific Apparatus, but the example set by the South Kensington Conferences will also be followed. The enormous building in the Trocadero contains a lecture theatre capable of holding upwards of 4,000 people. This will be used for lectures in scientific and kindred subjects, for which arrangements are now being made. It is impossible that the Trocadero buildings can be ready by May 1, so there will be ample time for these arrangements and for the others, to which we may briefly allude.

The French Association for the Advancement of Science will conduct a large number of scientific experiments on a great scale, and a large number of exhibitors will take advantage of the meeting of that association to exhibit experiments relating to their special pursuits.

Every facility will also be given to scientific societies for summoning to a special congress those prosecuting the same line of research. The number of these useful assemblies is increasing daily. It would occupy too much space to give a list of all the societies which will hold such meetings, but many circulars illustrating the development of this sectional movement have already been printed.

Lecture-rooms will be furnished *gratis*, lectures will be advertised on a large scale, and as far as possible, Government apparatus will be at the disposal of inventors for conducting the experiments required to illustrate their lectures. What has been done at the provisional Ethnographical Museum, may be considered as a fair specimen of what will be done on a larger scale at the Trocadero Palace, and other suitable buildings.

The Libraries of the United States.

The *New York Herald* announces that there is now completed at New York the Lennox Library, which is the most beautiful in the New World. Its founder, James Lennox, son of a Scotch merchant, died in 1870, and endowed it with a capital of £16,000 and a sum of £4,000 for the purchase of books. The value of the ground and building of the Lennox Library is placed at nearly £80,000. The edifice, which is all of white marble, rises in the middle of the Central Park. The architecture is an adaptation of the new Greek style. A large staircase leads to the principal entrance, which is ornamented with Corinthian columns of granite. The library, which is capable of containing altogether 1,000,000 volumes, is composed of three storeys in the middle building and two in the wings. Three great lecture-rooms have already been completed, and also a picture gallery. Nine librarians are attached to it. This magnificent structure, which New York owes to the munificence of James Lennox, is of unspeakable value to the student and the *savant*. For nearly half a century Mr. Lennox has not ceased to collect manuscripts, books, engravings, maps, sculpture, pictures, and works of art of all species, all of which he has placed in the new Library and handed over to the public. He has spared neither time or money to procure artistic and literary

treasures which eclipse, without doubt, those which were bequeathed to their native cities by the Vanderbilts, Stewards, and Astors. In all that concerns the history of America, the Bible bibliography and Shakesperian literature, these collections fill up a void which has long existed in the public libraries of the United States. They comprise complete folio editions of ancient Bibles, which are not to be found either in the great library at Boston or even at the British Museum. Among the most interesting contents of the Lennox Library are the first folio edition of Shakespeare, the Magazine Bible, Elliot's Indian Bible, the first Bible printed in America, and the complete copy of the Psalter of Bay State, which was the first book printed in English in the New World.

The Operation of the Adulteration Act in Ireland.

Our readers may be already aware that—except in a few large towns—the adulteration law has been a completely dead letter in Ireland, inasmuch as the Royal Sanitary Authorities were unwilling to appoint special officers to carry it into effect, and the constabulary authorities had issued orders to their men *not* to undertake the duty.

We feel satisfaction in learning that this latter decision has been rescinded, and that, in future, the constabulary will be ready to undertake the collection and care of samples when called upon to do so by the grand jury. This determination was communicated recently by a circular letter to all the grand juries in Ireland from the Inspector-General of Constabulary, who stated that, in the event of a local authority (which is the town council of any of the boroughs subject to the Act 3 & 4, cap. 108, within the limits of such borough, and in all other places the grand jury of a county) signifying a desire that members of the constabulary should be authorised to carry out the provisions of the Sale of Food and Drugs Act, 1875, the county-inspector would select one or two constables in each sub-inspector's district, whom he might think well fitted for the duty, and send names to the local authority, with a request that their town clerk or secretary (as the case may be) would sign and return to him a memorandum directing the constables so named to carry out the provisions of the 13th section of the Act, and to do all things incidental thereto, or consequent thereon. This memorandum would be sufficient authority for constables to enforce the law.

The Metric System in America.

In November last, the American House of Representatives adopted a resolution requesting the heads of the executive departments to report any objections which might exist to making the use of the metric system of weights and measures obligatory in all governmental transactions. The postmaster general reported that the expense of making the change and the general lack of knowledge regarding the system were the principal objections. The secretary of the navy saw no objection, excepting that, if applied to soundings, it would necessitate a total loss of all charts and chart plates now in use, and would interfere with their exchange with England. The war department admitted that the exchange is practicable, but the engineer corps will require five years to prepare for it; while the ordnance corps can be ready in one year.

Last month a bill was introduced providing that, for all postal purposes, 15 grammes shall be substituted for half an ounce, and so on, in proportion; and that after January, 1880, the metric system of weights and measures shall be obligatory.

A bill was also introduced to establish the metric system in the coinage of the United States, and to provide for an regulate the coinage, including the new coin metal called "goloid."

Relative Efficacy of Vaccination with Fresh and with Preserved Lymph.

The army affords a good field of observation with respect to vaccination, and the statement in the Report of the Army Medical Department, is, therefore, worth remarking that out of 22,302 recruits found fit for service, there were only 727 who had neither marks of vaccination nor small-pox, and that there was a slight increase in the ratio of recruits with marks of vaccination. Again, there were 10,358 soldiers vaccinated during the year with *fresh lymph*, and 17,269 with *preserved lymph*. Of the former there was a perfect vaccine vesicle in 4,717, a modified one in 4,400, a failure only in 1,241; whereas in the latter class the corresponding numbers are 5,346, 6,432, and 5,491. Thus, while the ratio per 1,000 of failures was only 119·8 when fresh lymph was used, it was 318·0 in the case of preserved lymph.

Unrecognised Heroes.

Vanity Fair notices, in warm terms, a hero of the Turkish campaign, of whom very little has been heard, but whose name fills every mouth of those who were at Kamarli, or in Suleiman's retreat. This hero, it says, is Dr. Gill, of Shrewsbury, of a presence by no means imposing, but with the touch of a woman and the heart of a lion, who left his country patients to take service with the Turks. He was always in the very front of the fight, wherever it might be, and at Kamarli he endured fever, dysentery, and starvation, rather than abandon his post. The Turks adore him, and both Baker Pasha and Captain Burnaby speak in the warmest terms of his courage, his skill, and his endurance. Another surgeon, who did most excellent work and greatly distinguished himself, is Dr. Heath, a nephew of Baron Huddleston, and a very fine fellow by all accounts. He is an Irishman, equally full of fight and surgery, and he has gained with the Turks more distinction than he could have got in many years by remaining in Ireland. It is right that these two brave men should not be forgotten by their own countrymen.

The Board of Trade wishes to consolidate the laws referring to weights and measures, and asks the Pharmaceutical Council if there is any reason why the old apothecaries weights should not be abolished. The Council objects, the only given reason being that if quinine, for example, should be afterwards sold by the drachm, it would not be legally possible to sue for the value! As if it would not be possible to charge for 60 grains.

Inhalation of Salicylic Acid in Croup.

In the St. Petersburgh *Med. Wochen.*, R. Otto says that, conceiving that croup is due to the presence of parasitic vegetations, he employed inhalation of solution of salicylic acid in the epidemic of that disease which invaded Lesetzt, in Livonia, in August, 1876. The treatment was applied in seven cases, and was commenced immediately on the appearance of the convulsive stage. In all cases the number of paroxysms was rapidly diminished, and the best results were observed in those children who were placed in rooms of which the temperature was kept equable. The author does not venture to assert, upon so few cases, that salicylic acid is an agent of great efficacy in croup, but he desires that this sort of medication should be tried on a large scale.

Board of Superintendence of Dublin Hospitals.

Sir Dominic Corrigan having retired from the Board of Superintendence of Dublin Hospitals, the Board have unanimously passed the following resolution :—

"That we receive with extreme regret the retirement of Sir Dominic Corrigan from this Board, of which he has been an active member since its formation in the year 1856. And, further, we desire to place on record our deep sense of the valuable services he has rendered by his constant attendance at its meetings, by his wise counsel in all its deliberations, and by his practical acquaintance with the organisation and management of the institution under its superintendence."

Steevens's Hospital, Dublin.

A number of changes have just been made in the staff, owing to the resignation of Dr. Henry Freke, Senior Physician to the Hospital, and Lecturer on Practice of Medicine in the School. Dr. Freke has been appointed a Consulting Physician, and Dr. T. W. Grimshaw becomes Senior Physician to the Hospital. Dr. Richard Bookey succeeds Dr. Grimshaw as Junior Physician. In the School, Dr. Grimshaw vacates the chair of Materia Medica, and becomes Professor of the Theory and Practice of Physic; Dr. R. Johnston becomes Lecturer on Materia Medica; while Dr. Matthew Fox has been appointed Lecturer on Botany.

Extraordinary (!!) Precocity.

The *Gazette Hebdomadaire* reports a case read by M. Lefebvre to the Belgian Academy of Medicine, noting the extraordinary precocity met with in a girl eight years of age, born at Oberpallen, Luxemburg. The child was born very fully developed, having hairs on the pubes. Menstruating at four years of age, she became pregnant at eight by a cousin thirty-seven years of age, who was sentenced to five years' imprisonment for her seduction. The pregnancy terminated by the expulsion of a mole containing a well-characterised human embryo.

The Royal Society.

So great is the desire for admission to the Royal Society, amongst certain classes of scientific men, that although only fifteen will be elected, more than fifty candidates have either directly or indirectly entered into competition for the honour. The list of foreign members was made complete (fifty) at the close of last year by the election of seven members; but since then, so great has been the mortality amongst the *savants*, that there are already six vacancies in the foreign list.

Treatment of Metrorrhagia by Hypodermic Injections of Ergotine.

M. C. Paul, in the *Bull. de Therap.*, gives the details of 14 cases in which the uterine hæmorrhage was arrested in from 5 to 16 minutes, by the following solution :—

Ergotine, 2 grammes;
Water;
Glycerin, āā, 15 grammes;

of which from 1 to 2 grammes were injected. M. Paul concludes that the hypodermic injection of ergotine is the most rapid and the most efficacious means that we have at our disposal in the treatment of metrorrhagia.

Trichinæ in the Flesh of Geese.

Sixty soldiers of the garrison of Thionville lately fell sick of trichinosis, and two of them died. It has been ascertained that the disease arose, not from pork, but from the flesh of geese which they had eaten.

Lady Hospital Doctors.

At Berlin there will be opened in the course of this year a hospital officered by lady doctors. Berlin has been for some time in possession of a clinic entirely managed by the lady doctors.

Eastern Epidemics.

The cholera has broken out with violence in Southern Arabia, at Mecca and Jeddah, among the pilgrims. The plague in Northwestern Persia has been steadily extending its ravages, especially in Resht and the neighbouring district. Either of these dreaded epidemics would prove particularly formidable in view of the massing of troops in Turkey and Egypt, and the unavoidable neglect of sanitary precautions.

Blatta Orientalis.

New Remedies says that the employment of the Russian cockroach as a remedy in uric varieties of dropsy has already attracted considerable attention. Those who have any desire to make a trial of it, can now obtain it of Lehn and Fink, 160 William Street, New York.

The population of the Netherlands, at the beginning of this year, is estimated at 3,865,456 persons. During the last quarter the birth-rate was equal to 37·2, and the death-rate to 22·1 per 1,000 living. The deaths of infants under one year of age, during the three months, were 7,755, and were equal to no less than 214 per 1,000 births registered; whereas the proportion in England was 138 per 1,000.

A new scientific monthly is about to appear, under the joint editorship of Drs. Ferrier, Hughlings-Jackson, Crichton Browne, and Bucknill, devoted entirely to psychological subjects. There are already two journals, a quarterly and a half-yearly, devoted to this subject by which we imagined the ground was already covered.

PROF. COPE has been able to take a cast of the cranial cavity of the Tapiroid genius Coryphoden, from the Wahsatch beds of New Mexico. This (says *Nature*) has revealed remarkable primitive characters: (1) the small size of the cerebellum; (2) the large size of the region of the corpora quadrigemina; (3) the cerebral hemispheres were small; and (4) the olfactory lobes were very large. The medulla oblongata is wider than the cerebral hemispheres. In profile the brain closely resembles that of a lizard. These characters are so extraordinary that Prof. Cope considers them sufficient to mark a primary division of mammalia, which he, following Owen, calls Protencephala. Prof. Cope describes and gives figures of a cast, the skull cavity, in the *Proceedings* of the American Philosophical Society, Vol. xvi., No. 99.

M. BOUCHET has suggested to the Académie des Sciences the employment of Hayem and Nachet's apparatus for counting the red corpuscles in blood, to estimate the number of fat globules in human milk. From this enumeration, the density and quantity of butter can be approximately estimated, and, although imperfect, has a certain importance in the analysis of human milk particularly, this liquid being, as a rule, obtainable in very small quantities, and not in sufficient quantity to use for a regular analysis.

IN future, medical officers are to be at liberty, in urgent cases, to attend the wives and children of soldiers married without leave, and to supply medicine for them from the public stock to a limited extent, at the discretion of the principal medical officer. In all such cases, the prescriptions are to be filed at the surgery for subsequent examination.

A WASHERWOMAN, at Courcelles, has just died in a most extraordinary manner. She was suffering from the toothache, and applied, with a sponge, to her gums some of the bleaching liquor used in her trade. The application caused a spasm of agony, in which the sponge was half swallowed, and stopping in her throat, choked her before aid could be procured.

WE regret to hear of the death of Dr. Thos. Prichard of Abingdon Abbey, Northampton, of malignant disease of the stomach. Deceased was a supporter and contributor to this journal almost from its commencement; his death will be sincerely mourned by all to whom his great attainments and genial disposition were personally known.

M. DUMAS announced to the Paris Academy of Sciences at its sitting on March 4, that an anonymous donor offers a prize of 6,000 francs to be awarded in 1880 to the person who makes the most useful application of M. Pasteur's researches to the healing art.

THE Secretary of State for War has placed the services of Surgeon-Major Falwasser at the disposal of the St. John's Ambulance Association for the gratuitous instruction of volunteers anxious to learn the duties in connection with field ambulances in case of war.

WE learn that Lord Conyngham has generously placed his steam yacht at the disposal of the St. John's Ambulance Association, for the conveyance of trained men, nurses, and ambulance materiel, in case of war.

WE are pleased to notice that a Memorial Fund has been opened in France to perpetuate the memory of the illustrious Claude Bernard. Great Britain is also asked to contribute, and Dr. Gerald Yeo, of King's College, London, has consented to act as hon. treasurer for this country.

THE Charing Cross, the Royal Free, and the Great Northern Hospitals, have each received £50, as portions of the proceeds devoted to charitable purposes, in the 1,000th representation of "Our Boys" at the Vaudeville Theatre.

THE Philadelphia *Clinic* reports an obstinate case of asthma which was entirely relieved by a two-grain pill of *Grindelia robusta* given three times daily. The medicine was thought to be the cause of a violent diarrhœa, which came on at the end of three weeks.

DISTRESS and disease are terribly on the increase in and around Constantinople, where 26,000 refugees are herded together. The cows are mostly affected with typhoid, and the disease is spread far and wide by the milk.

THE rates of mortality in the four principal towns of the United Kingdom last week was—London 23, Glasgow 26, Edinburgh 31, and Dublin 32 per 1,000 of the population.

SMALL-POX caused 34 deaths in London last week, being about 40 per cent. less than the preceding week. No death was registered from this disease in any other part of England.

IT is stated that one drop of the extract of eucalyptus, applied on cotton to sensitive dentine, just before excavating, serves as the best local anæsthetic.

DR. HUMPHRY, F.R.S., of Cambridge, has been elected Hunterian Orator at the Royal College of Surgeons of England for 1879.

RELIABLE reports state that the typhus epidemic in St. Petersburg baffles medical skill to arrest its progress, and the fresh cases average 300 or 400 a day.

AT a meeting of the Fellows of the College of Physicians of London on Monday, it was decided by a majority that the College is not disposed to make any alterations in their charter for the purpose of granting the diploma to women.

Literature.

ON IDIOCY AND IMBECILITY. (a)

Since the days when Hippocrates wrote of the usages of the Microcephali, great advances have doubtless been made in the investigation of cerebral disease and mental disorders. But while some point to a discrepancy between the results of psychological research, and the great interval of time which has elapsed since the Hipprocratic age, it may with confidence be urged that during the past half-century much has been done, not only to stimulate the study of psychology, but that abundant evidences exist to prove that this labour has not been in vain; and further, that modern mental research has done much to make up for the deficiencies of past generations in this sphere of medical science.

Among recent contributions to psychological literature, the work of Dr. Ireland on Idiocy and Imbecility, bids fair—and justly so—to become a classic work on the subject. Written in a clear, plain, unpretending style, this work of the Medical Superintendent of the Larbert Institution deals chiefly with facts and figures, and the author has done much to entitle him to the thanks of his professional brethren as well as the public, for both are intimately interested in the results of his labours.

The main features of the work are two-fold, and it is necessary to insist on these that his readers may justly estimate the intention of the author. Firstly, the knowledge hitherto extant on idiocy and imbecility is so scattered over the whole field of professional literature, that any one who would write an exhaustive treatise upon it, such as this work is, must be content to quote largely from these scattered materials. The task, though Herculean, we do not hesitate to say, Dr. Ireland has both wisely and conscientiously accomplished.

Secondly, the author has so utilised the vast amount of material at his disposal, that but a comparatively small portion of the work appears as original matter.

We conclude that a conscientious regard to the display of the actual truth on the subject, made the author somewhat diffident in advancing personal statements when he found the important facts expressed by others. If we have a suggestion to make, it is this: that being impressed by the able manner in which the author deals in an original manner with any question under his consideration, he should, in future editions, seek to substitute for the examples he quotes in the present work, others based on personal observations.

Idiocy is defined by Dr. Ireland as mental deficiency, or extreme stupidity, depending upon mal-nutrition, or disease of the nervous centres, occurring either before birth or before the evolution of the mental faculties in childhood.

"Imbecility is generally used to denote a less decided degree of mental capacity."

The statistics of idiocy at home and abroad are exhaustively considered. In the etiology of idiocy the author assigns to heredity a chief place, scrofula and drunkenness being the principal predispositions to its occurrence. In respect to the "Influence of Gynagogues," he quotes largely from, and adopts, the views of Dr. Seguin.

The classification which the author offers as an approximative one on idiocy, is based on his opinion, that we must have a pathological classification as well as a mental one. The following forms of idiocy are then discussed *seriatim:* Idiocy which is genetous, microcephalic, eclampsic, epileptic, hydrocephalic, paralytic, cretinism, traumatic, inflammatory, and lastly, idiocy by deprivation.

In genetous idiocy the diseased condition entailing deficient mental manifestation is complete before birth, and the term "genetous" the author deems preferable to "congenital," which may include the microcephalic, paralytic, or hydrocephalic varieties.

The remarks on the comparative and pathological anatomy applicable to this section, will well repay perusal. Another interesting chapter is that devoted to comprehensive records of the Bird Man, the Brothers Cerretti, Antonia, Grandoni, and Helene Becker.

In eclampsic idiocy, Dr. Ireland draws attention to the great degree in which intelligence is destroyed, and he regards the opinion of Echeverria, that the earlier the age at which epilepsy springs up, the deeper it undermines the organic and moral constitution, and the more disastrous are its results, as applicable to eclampsic idiots also.

The author's observations on the need of reliable information on the production of eclampsic idiocy, and respecting its pathological anatomy, suggest a rich mine for exploration to the pædiatric physician.

The bibliography of France, Germany, and Italy, supply materials for a highly-interesting and instructive chapter on Cretinism, including Lombroso's tables for those who wish to study the disease closely. The pathological anatomy of cretinism is a record of recent researches, and Dr. Ireland regrets the want, at present existing, of a series of good microscopical observations.

The chapter on Traumatic Idiocy will be read by psychologists with much interest, in conjunction with Dr. Crichton-Browne's valuable papers on Cranial Injuries and Mental Diseases, in the "West Riding Asylum Reports."

One of the most original chapters in this work is that devoted to the Sensory and Mental Deficiencies of Idiots, in which the relations of the five senses to idiots and imbeciles are fully considered, followed by an analysis of the mental symptoms.

The next two chapters treat of the best methods of education for idiots and imbeciles, and the relations of forensic medicine to this branch of psychology. In this part of the work, both the psychologist and the physician will find much material for thoughtful consideration, much to help them in their efforts to ameliorate the condition of a class of patients who will look to them for sympathy and relief; a help which now, thanks to Dr. Ireland, can be far more fully, readily, and efficiently accorded, than was possible previous to the publication of this highly-scientific, instructive, and interesting work.

(a) "On Idiocy and Imbecility," By W. W. Ireland, M.D. Edin, London: J. and A. Churchill. 1877.

THE SURGEON'S VADE-MECUM. (a)

No other living medical man besides Dr. Druitt has seen his work pass through so many editions, all of which have been unusually large for a publication in this department of science. No book has been so much read as this, from the many years back when it stood alone as an elementary book in surgery till now. The author has indeed been very useful in his generation. Students need elementary books, and this supplies the want. We do not know where a like one is to be found. Here is embodied an outline of the science and practice of surgery, and a very great deal of modern pathology. No subject, as we are told in the preface, is treated inexhaustibly, but the endeavour of its writer has been to render all descriptions accurate as far as they go, and to make the book a trustworthy foundation for the study of more complete treatises, and especially monographs.

Part the first gives a sketch of the elements of disease. Part the second describes the different injuries which sets those processes at work, beginning with mechanical injuries, heat and cold, and poisons organic and inorganic. In part the third each tissue and part of the body is taken in succession, with the various injuries and diseases which it is liable to. Part the fourth gives an account of the operations of surgery, both major and minor.

A very marked feature of this excellent publication is the manner in which the many special departments in surgery are treated. The chapter on the eye—perhaps the fullest of these chapters—is remarkably practical. We

(a) "The Surgeon's *Vade Mecum*." Eleventh Edition. By Robert Druitt, M.D. London: Henry Renshaw.

shall not go into a detailed review, but content ourselves with general observations. We much admire chapter xii., on scrofula and tuberculosis. It contains much original and good matter. Chapter xix., on diseases of the urinary organs, is a treat for the student. Section vii. embodies valuable remarks on intermittent or paroxysmal hæmaturia, an affection which has unfortunately made such ravages on the author, and driven him from an active and useful life. The chapters on operations will, no doubt, be favourite ones. Besides the very lucid and concise descriptions, rich woodcuts of illustrations adorn the pages, and further describe the subjects. We find in a foot note to page 784, that most of these necessary aids were sketched from a series of operations on the dead body, performed for the purpose of illustrating this work by Mr. Haynes Walton. This speaks for their accuracy.

It is with the fullest confidence that we recommend the "Vade-mecum" to all medical students; there is nothing in the range of surgery which he will not find, and put forth too, in a very inviting and truthful manner.

Short Notices.

(1) "The Mechanism of Natural and of Artificial Labour in Narrow Pelves." By William Goodell, M.D. Philadelphia, 1877.
(2) "The Quarterly Journal of Inebriety." America and London, Baillière, Tindall, and Cox. 1877.
(3) "The Chemical Theory of Contagium." By Lane Notter, M.D. London, Baillière, Tindall, and Cox. 1877.
(4) "On the Causes of Professional Opposition to Homœopathy." By Alfred C. Pope, M.D. London. 1877.
"Unsectarianism and Toleration in Medicine." By George Wyld, M.D. London: Trubner, and Co.
(5) "Amnesie Periodique ou Dedoublement de la Personalté." Par le Dr. Azam. Bordeaux: 1877.
(6) "New Remedies" (monthly), January, February, March, 1878. New York.
(7) "Report of the Health of the City of York, for the Quarter ending December 31st, 1876, and also for the Year 1876." By S. W. North, Medical Officer of Health.
(8) "Nathan the Wise." A Dramatic poem by Lessing. Translated into English blank verse, by Andrew Wood, M.D., F.R.S.E., &c., &c. Nimmo, London, Edinburgh.
(9) "On the Education and Training of the Feeble in Mind." By J. Langdon Down, M.D. London, &c. London: H. K. Lewis.
"The Obstetrical Aspects of Idiocy." By J. Langdon Down, M.D. London Ch. London: Adlard.
(10) "Wholesome Houses, &c." By Edward Gregson Banner, C.E. London: Crosby, Lockwood, and Co.

(1) This is a very interesting reprint of a paper read at the International Medical Congress at Philadelphia, and is characterised by a considerable degree of research and originality. Dr. Goodell's name is already well-known by his contributions to gynæcological literature.

(2) The temperance cause does not lack journals, and though there does not seem to be the amount of diminution in the revenue from spirits, proportionate to what ardent teetotallers would desire, still by perseverance, greater benefit must result to the community at large, by the spread of temperance literature. This magazine is well deserving of support.

(3) A very able *rêsumé* of the views and theories held in relation to *contagium virum*, being the substance of a paper read before the British Medical Association, Manchester, 1877. It is not alone, however, composed of the thoughts of other men, but Dr. Notter gives us his own on many of the moot points. There is a large amount of valuable information here condensed in a very small compass.

(4) We may safely bracket these two together, though Dr. Pope is more dogmatic than his *confrère*, Dr. Wyld. We need not again reopen this question, but look forward with hope to a possible future, when names will be of little value, and the professors of medicine united.

(5) Dr. Azam (Bordeaux) herein relates the history of a young woman whose existence is a dual one, one side normal, the other abnormal. Her case is a complex physiological problem, interesting to the biologist and the psychologist. Dr. Azam has published another somewhat similar case in the December number of *La Revue Scientifique*. Both papers will well repay perusal.

(6) This publication must prove invaluable to those who wish to keep *au courant* with the rapid introduction of new remedies and appliances into pharmacy.

(7) We have received a report in 1878, on the health of the city of York, for the year ending December 1st, 1876. York must be governed by some different regulations from other cities, or be behind the age.

(8) It is a pleasure to notice a work of this class, from the pen of a member of our profession. The time has gone by when the combination of literary pursuits with the practice of medicine was looked upon as an indication of neglect of those graver studies to which alone the physician was supposed to confine himself. Ignorant and uneducated competitors for fees favoured and fostered this idea, *mais nous avons changé tout cela.* Independent of the appreciation by the public of an accomplished scholarly physician with æsthetic tastes, the mind requires rest, and change of activity in a certain class of individuals, who must be working.

The physician must unbend his mind, if he desires to keep his mental powers unimpaired. Relaxation is a necessity. He must throw aside his stethoscope and thermometer, his visiting-list and case-book.

Æsop tells us how the bow, when always bent, becomes useless. Relaxation is secured in different ways; some by travel attain the desired object, whilst at the same time they derive professional advantages by visits to Continental hospital; but we do not know of any form of relaxation more agreeable than the one adopted by Dr. Andrew Wood. He, leaving the graver cares incident to his position, relaxes his mind, and amuses himself by culling flowers from Parnassus, by translating into English the thoughts of the poets of other nations. This task requires some of the Divine afflatus.

Dr. Wood is already favourably known by his translations of the satires and epistles of Horace, and of Schiller's "Don-Carlos," so that we were not quite unprepared for the intellectual treat he has given us in his rendering of "Nathan the Wise." It was Lessing's *chef d'œuvre*, and Dr. Wood has filled up a want by thus presenting it to English readers in an English garb. We need not expose the plot, which is interesting and moral, the inculcation of the doctrine of religious toleration being the main object of the drama. We must refer our readers to its pages.

We may safely say, this translation is faithful without being servile, and that Dr. Wood has ably and poetically, transferred the thoughts of Lessing into our tongue.

(9) Much has been done for the education and improvement of idiots and those of feeble mind by medical philanthropists. They have shown that it is possible by judicious management, and a combination of medical, physical, moral, and intellectual treatment, to elevate one of the most unfortunate classes in the community. The name of Dr. Down is well known in connection with this work, and his pamphlet, though short, embraces all the general principles necessary or advisable in dealing with this group of sufferers. It deserves a wide circulation. The second pamphlet has a certain bearing on the first, as it deals with some of the causes which lead to idiocy and mental impairment. He looks at the subject from its obstetrical side, a point of view which opens out a very wide and interesting field for further investigation. It is an interesting and useful contribution to the subject.

(10) The Banner system of sanitation is already well and favourably known, and the various contrivances of the inventor, to prevent the ingress of sewer gas into houses have

stood the test of practical experience. This pamphlet contains a clear and concise account of the system, and should be read by all who are interested in sanitary requirements.

Correspondence.

INSURANCE EXAMINATIONS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

DEAR SIR,—Having been asked by the agent of an Insurance Company to examine a life, being at same time furnished with forms, &c., I duly examined the life, and filled up forms.

The agent says, as the party about to insure did not take out the policy, he will not pay, and that I should look to the before-mentioned party.

My opinion of the matter is, that the agent having given the order, is liable after my having executed the duty on his order, but I would be glad to know your opinion, and perhaps that of some medical *confrère*, who may have been similarly circumstanced.

Yours faithfully,

J. P. M.

March 11, 1878.

[Certainly, if the agent gave a definite order for the examination of the patient, either verbally or in writing, without stating that the fee would be payable only on completed policies, he would be liable, and, in the interest of the profession, ought to be required to pay. The professional services of a medical referee cannot be made contingent on the acceptance of the policy, except by special previous arrangement.—ED. M. P. & C.]

Novelties.

A NON-RESINOUS TINCTURE OF GINGER.

THE great disparity of the various tinctures and essences of ginger of commerce as ordinarily sold for dietetic and medicinal uses, arises from the fact that they all contain a considerable quantity of an insoluble bitter principle. It is the resinous product that imparts an unpleasant flavour, as well as an offensive, opaque, muddy appearance to all aqueous solutions of the preparations of ginger of the British Pharmacopœia. Mr. Hay, manufacturing chemist of Hull, has succeeded, after various trials, in entirely eliminating this resin, and has just furnished the profession with a tincture of ginger which should entirely supersede the officinal preparation of the British Pharmacopœia. It mixes freely with water in any proportion, and while it loses nothing of its dietetic properties, it is unusually pungent and actively medicinal.

The ginger beer of the same manufacturer, made with this purer tincture of ginger, is extremely grateful and palatable. It is as clear and bright as water, and will probably keep any length of time, since it is freer from fermenting vegetable and resinous materials than the objectionable-looking and tasting article usually sold under this name. In fact it will be scarcely recognised under the old name, and is certainly preferable to some wines we have tasted under the name of champagne.

Medical News.

Dental Hospital of London.—The annual meeting of the governors of this hospital took place on Thursday last, at the hospital. Sir Charles Macgregor, Bart., presided. The report submitted by the committee was not of a particularly roseate hue, when looked at financially; the deficiency of income having compelled them with great regret to sell out £100 stock of the small invested capital of the hospital, in addition to a sale of £200 stock during the previous year. The Metropolitan Hospital Sunday Fund had awarded £72 11s. 8d., being a small increase on the previous year, and the Hospital Saturday Fund awarded the hospital £16 1s. The medical committee reported that they had treated 29,679 cases of different kinds, being 5,000 in excess of those of last year. In moving the adoption of the report, the Chairman said when they considered that over £500,000 had been sent out of the country for the Indian famine, and thus many sources of income had failed, they ought not to take too gloomy a view of the position.

St. John's Hospital for Diseases of the Skin.—The annual general meeting of the supporters of the above institution was held on Wednesday last, at the Westminster Palace Hotel. The chair was taken by the Hon. Mr. Massey, M.P. The Chairman, in moving the adoption of the report, remarked that the progress of the institution had been very considerably in advance of that of any previous year. Eleven additional beds had been provided, the expenses attending which had been reduced from £600 to £390 in the course of the year. The increase in applications for relief had compelled an increase to seven of the medical staff, and the attendance of the medical officers had been extended to eleven per week. The report having thanked the medical and other officers for their gratuitous services, proceeded to state that lectures on diseases of the skin, free to medical men and students, would be delivered during the coming April.

THE ORIGIN OF THE TURKISH BATH IN IRELAND.

THE introduction of the Turkish bath into Ireland has been commonly attributed to the late Dr. Basta, of Blarney, who certainly is entitled to the credit of having revived its use and made it popular. The actual pioneer of the bath in Ireland was, however, a native of the co. Kilkenny, named Patrick Joyce, who (under the assumed name of Achmet Borumborad, and in the guise of a Turk) first erected one about ninety years ago, in Beresford Place, near the Dublin Custom House, aided with grants of money by the Irish Parliament.

In proof of the above we refer our readers to "Sir Jonah Barrington's Personal Sketches and Recollections of his own Times," and in which also will be found a pleasant biographical sketch appertaining to the subject.

About the same time there sprang up in different localities throughout the country Turkish baths of a simple construction, named by the people "sweating kilns." They resembled lime-kilns, were of small size, had a hole for entrance at bottom, but covered at top, and inside was placed a stone seat. The heating apparatus was nothing more than a bundle of straw or furze set on fire, and when the smoke had cleared away the patient, divested of clothing, entered, and sitting down took a "ground sweat" *ad libitum*.

NOTICES TO CORRESPONDENTS.

NOTICE TO SUBSCRIBERS.—Subscribers who have not already paid their subscriptions are reminded that they are now due, and should be sent to the publishers, who will be happy to acknowledge their receipt. Subscribers who pay in advance will oblige by remitting, at the reduced rate of One Guinea, during the present month.

☞ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule

READING CASES.—Cloth board cases, gilt-lettered, containing 26 strings for holding each volume of the MEDICAL PRESS AND CIRCULAR

can now be had at either office of this Journal, price 2s. 6d. The postal regulations not allowing the Journal to be stitched, these cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

DR. JAS. ADAMS is thanked for his complimentary note.

REMARKABLE CURE OF CANCER.—In the window of a small jeweller's shop in the High Street, Wandsworth, is being exhibited a cancer extracted from a man's leg by the use of "Burgess's Lion Ointment." How long the lion was pulling away, or why the subject of its prowess should be in a jeweller's window when so many quack doctors or chemists would have been glad to pay a handsome sum for such a *rara avis*, accompanying information does not show. Bullocks, unfortunately, get unmercifully thumped, and as bruises and kernels look somewhat unsightly when the beast is killed, the knowing butcher extracts such cancerous excrescences. There are one or two butchers' shops in High Street, Wandsworth.

A CONSTANT READER.—We cannot give medical advice in our editorial capacity. Any experienced medical man can answer your question.

A YOUNG PRACTITIONER gives us a very short description of two cases, the treatment of which he desires to be suggested. In *costal rickets* gentle and even pressure may often be made upon the prominence with the result of somewhat relieving the deformity. In *caries of the spine*, where pus has formed, absolute rest in the recumbent position is an indispensable necessity, but if the case be spinal rickets and not caries, then Sayre's plaster-jacket with the head-support, if required, according to the condition of the cervical and upper dorsal vertebræ, is the most serviceable means to enable the patient to enjoy a healthful exercise.

DR. D. F.—Certainly, with pleasure.

L.R.C.P.—It is a disputed point which we should not like to take upon ourselves to decide.

DR. H. K.—Not yet received.

A DENTAL SURGEON.—See Parliamentary notices in Friday's daily papers.

ARMY SURGEON.—Yes, a capital work; you could not do better; it has but to be known to be appreciated.

DR. FERRIER will deliver the second of the Gulstonian Lectures at the Royal College of Physicians this afternoon at 5 p.m.; and the last of the course on Friday at the same place and hour. Subject: "The Localisation of Cerebral Disease."

PROF. FLOWER will continue his lectures "On the Comparative Anatomy of Man" at the Royal College of Surgeons, England, to-day, at 4 p.m; Friday and Monday next at the same hour and place.

ROYAL INSTITUTION.—Thursday, March 21, at 3 p.m., Prof. Dewar, "On the Chemistry of the Organic World."

HARVEIAN SOCIETY.—Thursday, March 21, at 8 p.m., Dr. Edis, "Cases illustrating the Diagnosis of Abdominal Tumours."—Dr. Ashburton Thompson, "Cases of alleged Maternal Impressions."

CLINICAL SOCIETY OF LONDON.—Friday, March 22, at 8½ p.m., Mr. Hutchinson: "Retinitis Hæmorrhagica; its connection with Gout, and probable dependence upon Thrombosis of the Vein."—Dr. Broadbent: (1) "Unusually rapid Effusion of Bloody Fluid into the Pleural Cavity at the age of seventy-six; Paracentesis; Recovery." (2) "Pleuritic Effusion; sudden Death without Paracentesis." Mr. Nunn: (1) "Electrolytic Treatment of Epulis." (2) "Plantar Bunion."

DR. PAVY, F.R.S., will deliver the first of the "Croonian Lectures" at the Royal College of Physicians of London on Wednesday next at 5 p m, the subject being, "Points connected with Diabetes." Members of the profession admitted on presentation of their cards.

COMMUNICATIONS, Enclosures, &c., have been received from—Dr. Polli, Milan. Dr. de Foumartin, Chelsea. Mr. Jabez Hogg, London. Dr. Dolan, Halifax. Dr. Kennedy, Dublin. Dr. Bartle, Liverpool. Dr. Offenberg, Wickrath, Prussia. Dr. Smith, New York. The Secretary, Statistical Society of London. Mr. Meadows, Hastings. Dr. James Adams, Ashburton. Dr. Sayre, New York. Mr. Bigger, Dublin. VACANCIES.

Ballinasloe Union, Kiltormer Dispensary.—Medical Officer. Salary, £112. Election, March 26.

Bath Royal United Hospital.—Resident Medical Officer. Salary, £100, with board, &c. Testimonials to the Secretary at the Hospital, Bath.

Blackpool.—Medical Officer of Health for the Borough. Salary, £100. Testimonials, &c., endorsed "Medical Officer," to be sent to the Town Clerk.

Bristol General Hospital.—Physician's Assistant. Salary, £50, with board and lodging. Election, April 25. Applications to the Secretary.

Cape Colony, Alice Dale Infirmary.—Obstetric Physician. Salary, £500, with house, servants, and horse free. Applications, with copies of degrees, which must be of a University in the United Kingdom, to be addressed on or before May 1st, to the Resident Physician as above.

East London Hospital for Children.—Resident Medical Officer. Salary, £60 per annum, with board, &c. Applications to the Secretary on or before April 11th at the Hospital, Shadwell, E. (See Advt.)

Lancaster Infirmary.—House Surgeon. Salary, £120. Applications to the President on or before April 3rd, accompanied with testimonials of moral character.

Lincoln General Dispensary.—Medical Officer. Salary, £150, with furnished apartments. Applications, with testimonials, to the Secretary.

Lurgan Union, Aghalee Dispensary.—Medical Officer. Salary, £100. Election, March 25.

Manchester Royal Infirmary.—Resident Surgical Officer. Salary, £150, with board, &c. Resident Medical Officer. Salary, £250, with board, &c. Resident Medical Officer for the Fever Hospital—Salary, £200, with board. &c. Resident Medical Officer to the Convalescent Hospital—Salary, £150, with board. Applicants must address the Chairman of the Board for either post, accompanied with testimonials, &c., on or before March 31.

Stafford General Infirmary.—House Surgeon and Secretary. Salary commencing at £100, with board, &c. Applications on or before March 26.

West Sussex Infirmary, Chichester.—House Surgeon. Salary, £80, with board, &c. An additional £20 is allowed for the duties of Secretary. Applications to the Secretary before March 30.

Worksop Dispensary, Notts.—Resident Surgeon. Salary, £220, with furnished apartments, &c. Applications to the Chairman of Committee by the 22nd inst.

APPOINTMENTS.

BLOMFIELD, A. G., M.R.C.S., House Surgeon and Secretary to the West Norfolk and Lynn Hospital.

BROWN, J. J., M.B., F.R.C.P.Ed., Medical Superintendent of the Fife and Kinross District Lunatic Asplum, Cupar.

CLARKE, F. W., M.R.C.S.E., Medical Officer of Health for the Bury St. Edmund's Urban Sanitary District.

DALE, H. R., M.R.C.S.E., L.R.C.P.Ed., Assistant Medical Officer to the Infirmary, St. George-in-the-East, Middlesex.

ELSMERE, E., M.B., M.R.C.S.E., Junior Resident Medical Officer to the Northampton General Infirmary.

GRIFFITH, J. De Burgh, B.A., M.B., M.Ch, an Assistant Medical Officer to the Worcester County Asylum.

LITTLE, W., M.D., M.R.C.S.E., Honorary Surgeon to the Royal Southern Hospital, Liverpool.

MERCIER, C. A., M.R.C.S.E., Resident Assistant Medical Officer to the Salford Union Workhouse.

O'FARRELL, H., L.R.C.S.I., L.K.Q.C.P.I., Medical Officer to the Eyrecourt Dispensary, Portumna Union.

RANSFORD, T. D., F.R.C.S., Honorary Surgeon to the Royal Southern Hospital, Liverpool.

SANDIFORD, J. O. G., M.D., C.M., House Surgeon and Apothecary to the South Charitable Infirmary and County Hospital, Cork.

TANNER, L. J. N., L.R.C.P.Ed., L.R.C.S.Ed., Assistant Medical Officer to the Cork District Lunatic Asylum.

Deaths.

ADAM.—On March 11, at Boston, Lincolnshire, Marion, the beloved wife of A. Mercer Adam, M.D., aged 45.

BAGG.—On March 13, at Priors Marston, Warwickshire, G. Wm. Bagg, M.R.C.S., aged 58.

COWARD.—On Feb. 25, at Church Road, De Beauvoir Square, George William Henry Coward, L.R.C.P.Ed., aged 67.

DILL.—On Feb. 14, at Manchester, John Dill, M.D., aged 54.

DOBBIE.—On Feb. 26, at Morton Villa, Dumfries, James Dobbie, M.D., F.F.P.S., of Great Kelvin Terrrace, Glasgow.

DONALDSON.—On Feb. 23, at Newmarket, co. Cork, Ebenezer Donaldson, M.D., aged 68.

JACK.—On Feb. 24, at Glasgow, John Jack, M.D., aged 31.

MURRAY.—On March 6, at Kersknowe, Roxburghshire, John Murray, M.D., aged 75.

MCBRIDE.—On March 7, at Newry, co. Down, Ann Eliza, wife of Andrew McBride, M.D., aged 36.

OSBALDESTON.—On March 3, at Hatfield, Herts, Thomas Osbaldeston, L.S.A.L, aged 82.

RIVERS.—On March 4, at Ipswich, Robert Rivers, M.R.C.S.E., aged 65.

THOMSON.—On Feb. 5, at Glasgow, Thomas Thomson, L.R.C.S.Ed., aged 71.

PROVIDE AGAINST ACCIDENTS
By taking a Policy of the
Railway Passengers' Assurance Company,
The Oldest and Largest Accidental Assurance Company.
Right Hon. Lord KINNAIRD, M.P., Chairman.
SUBSCRIBED CAPITAL, £1,000,000. ANNUAL INCOME, £210,000
A fixed sum in case of Death by Accident, and a Weekly Allowance in the event of Injury, may be secured at moderate Premiums.
Bonus allowed to Insurers of five years' standing.
ACCIDENTS OCCUR DAILY!
£1,230,000 have been paid as Compensation.
Apply to the Clerks at the Railway Stations, the Local Agents, or 64 CORNHILL, LONDON.

THE LOCALISATION OF CEREBRAL DISEASE.

BEING THE

Gulstonian Lectures delivered before the Royal College of Physicians of London.

By DAVID FERRIER, M.D., F.R.S.

(AN ABSTRACT).

Lecture II.

The lecturer then came to the effects of lesions of the motor region. The motor area includes the bases of the three frontal convolutions, and the convolutions bounding the fissure of Rolando, viz., the ascending frontal, and the ascending parietal, with its upper continuation termed the postero-parietal, or superior parietal lobule, and the inner aspect of the same or para-central lobules. The homologous regions of the monkey and man, are sufficiently close not to require long-detailed anatomical description. Within the area are situated certain definable areas, stimulation of which causes definite movements of the opposite side of the body; any destruction of which causes paralysis of the leg, hand, arm, or face; one or more, or all, according to the part and the amount destroyed. The Sylvian artery supplies this area, and the arrangement is such that the cortical branch may be blocked without interfering with the basal branch; consequently we may have cortical softening without morbid change in the parts below. This area is liable to irritative and destructive lesions. Irritative lesions cause convulsive phenomena, while destructive lesions cause paralysis. There can be no destructive lesion here without paralysis. A case was then referred to of a cyst situated in the motor zone without motor affection, but here there was no proof that the tissue was actually destroyed. When a case is found of lesion in the area without motor disturbance, then this may be considered as disproved. Electrical application to this area produces movement, and destruction of it paralysis, just as stimulation of a motor nerve leads to movement and destruction of it to paralysis. The characteristic of lesions of the cortex of this motor area is paralysis of the opposite side without loss of sensation in it. The paralysis affects the most volitional movements, while bilateral movements are little affected. The nearer the extremities the paralysis the more complete it is, as the hand more than the arm, while the muscles of the trunk are not easily affected. Cortical paralysis is accompanied by early rigidity; and if the destruction of the cortical substance is complete, the paralysis is of permanent duration, and sooner or later is followed by rigidity, and secondary sclerosis of the motor tracts. Then some illustrative cases were quoted. In some cases limited lesions of the cortex have been found associated with a greater degree of paralysis than can be accounted for by the mere anatomical extent of the lesion described; the anatomical area does not always correspond in extent to the functional disturbance. Different sections of the brain were then described by means of a number of illustrations. It is only lesions of those portions of the centrum ovale (of Pitrés) which correspond to these motor centres that are invariably followed by secondary degeneration of a sclerotic character and certain paralysis. Early rigidity and spasm, which are so characteristic of effusion into the lateral ventricle, are due to irritation of the fibres of the fronto-parietal fasciculi of the centrum ovale. In limited lesions paralysis may be greater than, and not merely co-extensive with the seat of injury, and in these cases recovery may take place of all the paralysis, except that connected with the part distinctly injured. The lecturer went on to speak of semi-lateral oculo-motor monoplegia, and quoted some cases of this affection. In cases of hemiplegia there is rotation of the head and eyes to the side of lesion, because the centres of one side no longer antagonise those of the other. Crural monoplegia is due to a lesion of the postero-parietal lobule and upper part of the ascending convolutions. In a case where the injury was near the sagittal suture the leg and arm were paralysed, and the paralysis was recovered from in trephining. In the case of a tumour growing in this region, there was first paralysis of the leg, and afterwards of the arm. The tumour was

three inches in diameter, and was situated in the upper part of the ascending parietal. Attempts to ascertain if any changes went on in the motor areas of an amputated leg were not yet satisfactory. There were great difficulties to be encountered. In the case where a thigh had been amputated twenty years ago there was found to be atrophy of the upper part of the ascending frontal convolution. In one case there was a linear depression at the proper centres, but this had not been examined microscopically.

Such observations, however, were very suggestive. Brachio-crural paralysis generally occurs in lesions of the motor centres situated at the head of the fissure of Rolando —the brachial and the crural centres being located closely together. Cortical lesions in infants are not altogether the same in their consequences as similar lesions in adults, according to M. Charcot. In a case of congenital absence of power there was atrophy of the corresponding motor convolutions, and an illustrative photograph by Dr. Gowers was passed round. Brachio-facial paralysis is more common than either brachial or facial paralysis alone ; it is due to a lesion in the mid-frontal region, or somewhat lower. Facial paralysis affecting the lower portion of the face is rarely found with a cortical lesion. A case was then given of facial paralysis due to an abscess of a certain spot following a gun-shot. As to aphasia, he would not go into its history ; it was due to lesions in the oral and lingual centres, commonly known as Broca's convolution. It is frequently accompanied by right hemiplegia. Here there is not speechlessness from inability to articulate; but the patient is unable to think in words, *i.e.*, to use those words which would correctly represent his thoughts. It is not absolutely confined to the left hemisphere ; and in many cases where the lesion has occurred in the right side the patients have been found to be left-handed. For those who denied this association of paralysis and lesion it would be necessary for them to show that such a bilateral lesion could occur without the paralysis. In a case of bilateral lesion of Broca's region, reported by Dr. Barlow, there was both aphasia and paralysis of articulation. Such paralysis is most commonly produced by an embolism of the middle central artery. As to the diagnosis of cortical paralysis from that due to lesion of the corpus striatum we have nothing definite to guide us. In paralysis of cerebral origin, the parts most distinctly paralysed are those which are most volitional ; thus, the arm is more paralysed than the leg, and the hand than the arm. Late rigidity is associated with secondary descending degeneration of the motor tracts. There is some doubt as to the effects of cortical lesions upon the temperature of the paralysed parts. Complete hemiplegia is not the most common, but a limited or dissociated paralysis becoming a complete hemiplegia. Cortical lesions are less frequently associated with loss of consciousness than are lesions of the corpus striatum and the vasal ganglia. They are more commonly associated with localised pain than are central cerebral lesions, and this can often be detected by percussing the skull over the seat of the lesion.

ON DERANGEMENT OF VISION IN HYSTERICAL PATIENTS.

(*A Lecture delivered in the Salpêtrière Hospital, Paris, by* Professor CHARCOT).

Translated by ARCHIBALD H. JACOB, M.D., F.R.C.S.,
Formerly Ophthalmic and Aural Surgeon to the City of Dublin Hospital, and the Dublin Eye and Ear Infirmary.

IN one of his late lectures in the Salpêtrière, M. Charcot has called the attention of his auditors to some of the derangements of vision most commonly observed in hysterical patients. To the facts belonging to this category, described by him on various occasions, and which he has since called to mind, he has added others that have not yet been noticed.

M. Briquet, it is well known, has long since mentioned the existence of various morbid phenomena which occur in that side of the eye, which is the seat of hemi-anæsthesia. On this side the patient sees badly, and the outlines of objects are not clearly defined ; the sheets of the bed or white paper appear grey, printed characters are not of a clear black, and are often so indistinct that the patients cannot read ; they merely see something of a deep grey colour on the light grey of the book. When the anæesthesia is carried to the highest degree, it gives place to amaurosis. (*a*)

It is owing to M. Galezowski, that we know this kind of amblyopia is regularly accompanied by dischromatopsia or achromatopsia, that is to say by a defective power, or absolute want of power to distinguish colours.

It is remarkable that this perversion of vision, with regard to colour, works according to certain rules, and certain laws, as has been clearly proved by M. Landolt, by means of a series of investigations on the patients under the charge of M. Charcot.

In its normal condition, all parts of the field of vision are not equally fitted to receive colours. There are some colours for which, physiologically speaking, the field of vision is more extended than for others, and these differences are reproduced nearly in all subjects, according to a rule for each colour. Thus, in the majority of cases, it is to blue that the field of vision presents the greatest extent ; then comes yellow, then orange, red green, and at length violet, which can be received only by the most central portion of the retina.

In hysterical amblyopia, these characteristics of the normal condition show themselves exaggerated to various degrees. In such cases, the different circles which correspond in the *exploration* (*b*) to the limits of the power of sight for each colour, contract concentrically in a more or less accentuated manner, according to the known law of the normal condition. From this, the numerous combinations which will be produced in cases of hysteria where this species of amblyopia has reached a high point, can be easily understood.

The circle of violet, the *central* colour *par excellence*, is capable of contracting, so as to become absolutely extinct, and the patient, while able to distinguish clearly all other colours, would be incapable of recognising violet ; then, the disease increasing, it would be the turn of green, another *central* colour ; then the turn of red, then of orange. Yellow and blue, *peripheric* colours, would continue to be distinguished until the disease had reached its furthest limit.

These are, as has been shown by observation, the two colours of which the perception is longest preserved in hysterical emblyopia. There are, however, as might be expected, exceptions to the general rule, in this sense, that certain patients (and such cases are not rare, as M. Charcot has recently proved)—continue to distinguish red when all perception of yellow, and even of blue is lost ; but, says, M. Charcot,—it may be considered as a certain rule, up to the present, that the *central* colours, green and violet, especially the latter, cease to be distinguished before the perception of red and the other colours generally is lost.

On further development of hysterical amblyopia, it may happen that all colours become completely indistinguishable, while the idea of form is preserved, and all objects present themselves to the eyes of the patient somewhat with the appearance of a drawing in sepia. At length, in its last stage, hysterical amblyopia may give place—of this, however, cases are rare—to veritable amaurosis. (*c*)

These chromatic alterations of the field of vision show

(*a*) "Traité Cliniq. et Thérap. de l'Hystérie." Pp. 293.
(*b*) Landelt. "Legons sur le Diagnostic des Maladies Desyeux." P. 155.
(*c*) Charcot. "Legons sur les Localisations Cérébrales." P. 118

themselves principally, as has already been stated, in the eye corresponding to the side affected by hemi-anæsthesia; but the field of vision becomes at the same time narrower for colours (to a much less degree, however) in the eye at the opposite side. This is why it is common to meet with hysterical patients who, for example, distinguishing with the left eye—that corresponding to the side affected by hemi-anæsthesia—only the *peripheric* colours—viz., yellow and blue, but have lost in the other eye all perception of the central colours—firstly, violet, then green. Theoretically, the existence of a multitude of other combinations, founded on the same principles, can be easily comprehended; and these combinations find daily their realisation in clinical surgery.

It should be well understood, however, that these derangements of vision caused by hysteria are entirely functional, and that they are not accompanied in the body of the eye by any alteration visible to the ophthalmoscope. The pupil and the retina are in their normal condition. The comparative examination of the eye on both sides shows no appreciable difference in the vascularity of the various parts.

It must, in addition, be stated that these symptoms, as a whole, may present the same peculiar mobility as the other local manifestations of the hysterical diathesis, and, like these, show themselves and disappear suddenly, or, on the contrary, establish themselves as persistent phenomena.

Thus, for example, dischromatopsia pre-existing, and more or less permanent in a certain patient, will give place suddenly to complete achromatopsia, at the time when the patient, feeling the attack of the premonitory aura, is menaced by a convulsive onset, and the achromatopsia will disappear as quickly after the attack as it was produced.

Complete amaurosis affecting both eyes may also momentarily establish itself in the train of this attack, (*a*) while anæsthesia, passing its usual limits, may invade the whole extent of the body. It may also happen that muscular amaurosis or complete blindness will be spontaneously developed, either suddenly or progressively, without having been preceded by the convulsive storm. (*b*) Finally, as may be foreseen, from what has already been stated, complete amaurosis affecting both eyes is a comparatively rare occurrence in hysteria. Briquet has only met with it three times. (*c*) He cites as exceptional the cases described by Pomme, Allègre, and Landouzy.

M. Charcot has scarcely observed it more often than M. Briquet. On the contrary, dischromatopsia, achromatopsia, and even complete amaurosis of one eye, that which corresponds to the side which is the seat of hemi-anæsthesia, and of the ovary, are phenomena common in such cases.

(*To be continued*)

ON SYPHILIS AS IT AFFECTS THE BRAIN AND NERVOUS SYSTEM.

By THOMAS STRETCH-DOWSE, M.D., F.R.C.P. Edin.,

Late Physician-Superintendent to the Central London Sick Asylum, Highgate; Physician to the North London Hospital for Consumption and Diseases of the Chest.

(*Continued from page* 167.)

THE second mode of invasion of the nervous system is that where the membranes of the brain and cord are primarily the seats of syphilis. When occurring in the dura mater alone, it may be localised, and not associated with a more diffuse arterial change. In a measure the same rule applies when the advance is made from without to within; when the membranes and the brain substance are successively invaded. But when, on the other hand, diffuse miliary gummata exist in the pia mater, causing softening and destruction of the convolutional surfaces beneath, then diffuse cerebral arterial change may be anticipated.

We will now see how these two states may be diagnosed; the prognosis of the former is hopeful, the prognosis of the latter is without hope.

Of all diseases of the nervous system, no less than that of other diseases, *pain* is one of the most important elements to be taken into consideration in the diagnosis; but in syphilis of the brain and its membranes, *Headache* in reference to its periodicity, its radiation, its advent and departure, as well as the inference to be gained by the effects of treatment, is perhaps of all aids the most vital and most significant. But let me add, that although I lay considerable stress upon this point, we must not be led astray by the existence of one factor alone, let it be of ever so much weight in itself.

For my own part I know of no cerebral growth that produces the peculiar pain which is so exceptionally diagnostic of a syphilitic gumma, and it is in all probability because these are found at the cortex, and in connection with the brain membranes. I have never seen, and I am inclined to doubt the existence of an isolated gummatous tumour in the central substance of the hemispheres, or motor ganglia, in the same way that we often find glioma, sarcoma, and tubercular growths. I have shelled out sarcomatous tumours from a man's brain, aged 29, who never suffered from any cerebral symptoms, pain, or otherwise, until a fortnight before his death, and in reference to tubercle, we have age and location to guide us. Gumma of the cerebellum is rare. The cerebellum is the most frequent seat of tubercle. I showed at the Pathological Society (see Path. "Trans.," vol. xxvii.) an enormous glioma in a man's brain who had rarely suffered from pain.

I do not wish here to draw out a differential diagnosis between cerebral growths, but the importance of *headache* in making a differential diagnosis of the seat of the syphilitic lesion will be readily seen and acknowledged. There is no description of *headache*, and one might say no kind of *pain*, which equals in intensity that which results from a localised syphilitic hyperplasia of the *dura mater*.

It is of a different character altogether to that which has been described in Case 10; and it is important to remember that it matters not whether the neoplasm is situated at the base, and involving the tract of some important nerve, or whether it is over the surface of the hemispheres in contiguity with any special sensorial or motor functional area. Why this membrane under these circumstances should be so sensitive it is not easy to explain? Yet we know by experiment that the dura mater is very sensitive to the electric current, and that the most violent and general muscular movement results from its action. And again, the nature of the texture invaded by the growth has to be taken into consideration. When once the inflammatory action has ceased in the membranes, and the brain substance becomes attacked, then, and not till then, does the *pain* lose its intensity.

The invasion of parenchymatous structures by morbid growths is never attended by the *severe pains* which are associated with them in more compact textures. The former condition of pain is much more diffuse than that where the bone is primarily involved, although it cannot be said to produce a more general hyperæsthesia of the scalp. The latter form of pain will sometimes extend to all the muscles of the neck and upper extremity, inducing very severe hyperalgia. *It is not relieved by pressure.* On the contrary pressure if possible *increases* its severity.

Again, this pain is remittent; it thus differs from the case just alluded to where it was found to be relapsing. (See tables of characters of pain in "Syphilis of the Brain," &c.)

In addition to the peculiar nature of the pain, where the dura mater is the special seat of syphilitic disease, we find signs and symptoms according to the particular area implicated, which we can only deal with in a very general way.

(*b*) "Voir l'obs., complete dans Bourneville et Regnard, Temographie Phot. de la Salpêtrière." Pp. 129, 151.

(*c*) *Loc. cit.*, p. 293.

Muscular hyperalgia, and disturbance of muscular sense, with cramps of isolated or combined groups of muscles, are of all others perhaps the most important. Epileptic seizures may occur, but when they do it is a sure sign that the growth is making advances toward the convolutional cortex, if it has not already invaded it. Although the pain is so diffused, the temperature of the head is locally increased, so that temperature and pain bear an inverse ratio to each other, and often the precise seat of inflammation can be detected by this means.

Lastly, a pseudo-ptosis and a contracted pupil are associated on the same side as the lesion when it exists in relation with the anterior lobes, although the third nerve is not directly affected.

With this review of the signs and symptoms usually attendant upon a gumma of the dura mater proper, we will now consider what the signs and symptoms would be if this growth were allowed to extend itself into the brain substance, and to consider this is a question of pathological interest. How far these gumma are merely the sole local manifestations of syphilis is uncertain, and it becomes a point for consideration whether they are or not usually associated with the syphilitic vascular changes of Heubner.

From my own observations I conclude that the latter is the real condition, only in the more advanced stage of the growth. On the other hand, it is common pathology to find syphilitic disease of vessels and softening of the brain without gummatous growths.

If this be true, and my own experience confirms it, we have in syphilis of the brain a diffuseness as well as a vagueness in the manifestations.

And here again we find another point of interest which helps us to diagnose a syphilitic from other forms of tumour. For instance, a man has a paralysis of his *left* third, sixth, and seventh nerves, and a palsy of his *right* arm and leg. It would be inferred that he had some lesion of the *left* hemisphere of the brain, possibly in the pons varolii or crus cerebri. If the lesion were due to hæmorrhage, to a sarcomatous or gliomatous tumour, would the state of that man be actually the same, provided the lesion were syphilitic? We will for the present leave history and age out of the question altogether, important aids though they be to diagnosis.

If we use the ophthalmoscope we shall probably find some ischemic or neuro-retinal change, which will avail us little, and the same may be said if we examine the palsied members; no electric current will help us to come to a correct estimate, but there will be diffuse changes revealing psychical derangements, which I maintain are rarely associated with other than syphilitic growths when combined with objective signs of paralysis.

Some of these conditions have been noted in the chapter on "Pathology," and will be referred to again.

The following case will possibly demonstrate my meaning:—

CASE 14.—*Gumma of Pons Varolii, involving the 3rd, 5th, and 7th Nerves—Slight alternate Hemiplegia of Sensation and of Motion—Complete* Right *Facial Paralysis, and Intense Neuralgia of the* Right *half of Head and Face—Disturbance of the Sensorium—Recovery.*

S. B., æt. 42, contracted syphilis, and suffered greatly rom it when 19 years old. At 23 years of age he went to India, and whilst there he had fever and ague; he also had sunstroke. But it was not until he was 40 years of age that he suffered severely from headaches. So severe were they at first that he was unable to sleep for nights together. If he took any excess of stimulant, to use his own words, he became like a madman. He placed himself under medical care, *and got quite well*—so much so, that he said he felt as well as ever he did in his life, but when he became excited, and especially if he lived too freely, *his head felt heavy, and he lost himself momentarily.*

At other times his memory failed so that he would break off in the midst of a sentence, and forget the nature of the subject of which he was speaking. Sometimes he became embarrassed in his speech, and would misplace a whole sentence or give one word for another, or his speech would become of the drawling, hesitating character to which we have before alluded (Case 10).

At the age of 42, his headaches recommenced, and he became morose, irritable, and violently passionate, or he would burst out into a fit of crying. He complained of a weakness in the *right* arm and leg. A month before he came under my care, in 1876, he awoke one morning to find that there was loss of movement of the *right* side of the face. Three weeks after he saw double with the *left* eye, and had very great difficulty in raising the left eyelid.

When I saw him his extreme pallor attracted my attention, and as far as facial expression was concerned, he at first sight appeared to be demented, but this was by no means the case, for he at once gave me his history clearly enough. There was no marked failure in reasoning power. He suffered from the most agonising pain in the *left* half of the head, face, and jaws, extending well round to the occipital region. This pain was purely paroxysmal—it usually came on about seven o'clock in the evening, and continued until four or five on the following morning. He was rarely giddy, but whilst walking he would stop, and say that he felt confused.

1st nerve normal; 2nd nerve involved. He says that the sight of the *left* eye is not so good as that of the right. The ophthalmoscope showed no difference—the discs were dim and hazy, they seemed swollen and the veins enlarged.

3rd nerve. Both of the pupils were greatly contracted, and the left eye seemed to be at a standstill, as though the 6th and 4th, as well as the 3rd, were palsied—there was partial ptosis.

5th nerve. There was intense hyperalgia of the sensory branches of the 5th on the *left* side. He also complained of great stiffness about the muscles of the jaws.

7th nerve. The paralysis of this nerve was almost complete, and associated with profound anæsthesia.

8th, of the glosso-pharyngeal and pneumogastric nerves, the latter was not involved, but the spinal accessory seemed to be so, for at times there was rigid spasm of the trapezius muscle.

9th nerve. The tongue was slightly pushed over to the *right*—its *right* half seemed atrophied when compared with the left, and this side was furred and coated (trophic nerve derangement), whilst the left half was usually clean. The sense of taste on the right side was decidedly impaired.

Of the extremities, the *right* was first involved, but more to sensation than to motion, and more of the arm than of the leg—the paralysis was slight. The left arm and leg were also paretic, only to motion not to sensation.

I must admit that I looked upon the case as hopeless, and stated that to be my opinion, but knowing that the man had contracted syphilis, feeling sure that the tumour was of the nature of a gumma, and seeing from signs and symptoms that it was localised, and possibly originating in the dura mater, covering the basilar process of the occipital bone, I commenced the treatment by giving half-dram doses of iodide of potassium with decoction of bark, three times a day. This was continued for six weeks with some slight improvement, especially in the patient's general health. His appetite became good, and he was fed freely.

Stimulants were at first administered, but with caution. The iodide was now discontinued, and three grains of blue pill were given, night and morning, for one month. There was slight ptyalism, but the mercury was continued with a mixture of quinine and chlorate of potash with which he washed out the mouth before swallowing. The man's slow, but sure progress was really remarkable. The ptosis of the left eye and vision were the first to become normal, at which time the nocturnal pains ceased, sensation returned to the right side of the face, and the paralysis—although never completely cured, was scarcely noticeable.

He was under my care for six months, and from a mere wreck of humanity he became himself once more, and I

hope he is taking iodide of potassium to this day, for I told him to do so.

There is nothing either novel or exceptional in this case, for we are constantly meeting such in our practice, but I was anxious to draw attention to it, because in addition to the signs of a tumour situated at the base of the brain, we had the disturbance of the sensorium ; and independent of any other sign, this would at once lead me to suspect, but not to be certain, of the existence of syphilitic disease, probably of the vessels. And beyond this it was at that particular stage, which convinced me also that softening had not taken place. There is one important factor, however, which if not taken into consideration would invalidate our diagnosis. I refer to the existence of albuminuria in association with a gliomatous mass occupying precisely the same position, and producing similar signs and symptoms to those which this case has presented.

When the blood is loaded with urea, and the capillaries have undergone atheromatous and fibroid changes, and we find undue tension of the vessels we might have accompanying these objective signs, the subjective symptoms of mental perturbation, which have been observed, but no clinicist would permit this state to pass his notice unheeded. And withal, when we come to consider the degenerative changes of the brain which arise from associated renal and vascular disease, and when are added to these history and general textural changes, we find this class of paralysis to stand out from all the rest with a clearness most unmistakeable.

Before considering the signs of disease of the brain produced by the arterial changes in the middle-sized leading cerebral vessels, as described by Heubner, we must first refer to a similar condition commencing in the vessels on the cerebral surface of the pia mater.

This is often associated with disease of the medium sized vessels of the brain, but as a rule when co-existent, it has invariably preceded, so that a differential diagnosis is necessary.

The signs of syphilitic inflammatory hyperplasia of the pia mater are to be distinguished from those of the dura mater. A syphilitic inflammation of the dura mater resolves and the patient gets well. A syphilitic inflammation of the pia mater is usually less circumscribed, rarely resolves, invades the grey substance, and produces softening and atrophy of the cortex, also of the convolutions, and the patient dies demented in two, three, or four years. The chief reason for this is that the disease progresses without showing any objective signs (at least to the patient's friends, or to any ordinary observer) more than *slight* headache, with increase of temperature of the head toward night, and all the feelings accompanying general *malaise*, until, to the surprise of himself and those about him, he is suddenly seized with an epileptic fit. After this he is more carefully observed, and sensorial rather than motor phenomena are noticed. Or the fits may relapse, and be continuous at intervals for days or even weeks, according to the extent and course of the lesion, and the invasion of the discharging centres. Some objective paralysis might follow them—generally defect in co-ordination of unilateral, or, it may be, bilateral, groups of facial muscles, and of the muscles of the tongue ; or a pseudo-hemiplegia may be the result. The seat of this inflammatory change, for what reason I know not, is almost invariably over the convolutions of the anterior lobes, and very rarely over one lobe alone.

We observed that the headache in syphilitic disease of the cranial bones and of the dura mater was most intense, and increased by pressure—that the increase of temperature was usually localised rather than diffused. The reverse of this is the case in syphilitic inflammation of the pia mater ; there is no intensity of pain ; it is never localised, but invariably diffused over the forehead, and of a dull, aching, congestive kind. The temperature of the head particularly, and of the body generally, is higher than when the dura mater is alone involved. There is greater constitutional disturbance ; vomiting and constipation may occur, but alteration of character is a sure accompaniment — illusions, hallucinations, delusions, melancholia, and dementia the sequence. Case 10 is an excellent illustration of this form of disease, and the signs and symptoms are fully delineated and dwelt upon, so that it is unnecessary here to say anything more about them.

The following case is one which came early under my care, and yielded to treatment :—

W. J., æt. 37, married, and (lately) of extremely temperate and regular habits, but, when young, he contracted syphilis, and suffered severely from it even until a very recent date. He was engaged in a large way of business, and, for the past year or two had been much harassed on account of business matters. He attributed the headache from which he suffered to this cause. His friends became alarmed about him on account of the remarkable and almost sudden change in his disposition. His honesty and strict integrity were never doubted, but now his chief aim seemed to be to enrich himself at any cost, and he would tell his dealers to make the most exorbitant demands—to say the least of it, in the most unbusiness-like way. His feelings also towards his wife and children had undergone a change which, to them, seemed unaccountable. He had been under medical treatment, and, not getting better, an acquaintance of mine, who was a friend of his, advised him to consult me.

When I first saw him, in May, 1877, he gave me the impression of being in fairly good health, and he told me that he was perfectly so in every way. His memory and general intelligence were good. I thought that I occasionally detected some tremor in articulation, and I was determined to put this very conclusive proof to the test by inducing an exaltation of function in the motor ideational centres, and I told him that he would oblige me by repeating for one dozen times the two words "proceed procrastination." Of course he said nothing was easier, but before he had arrived at the seventh time his articulation was a mere jumble, and the inco-ordinate movements of the lips and facial muscles, with his apparent anxiety to accomplish the task, told me at once a true tale. As he was leaving my house he fell down in a fit—the first he ever had. I told his friend my opinion of the case, and, after a little persuasion, he was induced to place himself under the treatment I suggested.

The rooms of his house were cheerful, lofty, and well-ventilated. I ordered him to take plain roast or boiled meat, to abstain from alcohol in every form, particularly to discontinue smoking. Tea and coffee were forbidden, and all business pursuits. He was to take carriage, but not walking exercise. I particularly enjoined him to discard all inclination to sexual indulgence. The treatment I adopted was active (I do not believe in bromide and iodide of potassium unaided in these cases), for if this condition is allowed to progress beyond a certain point—then all is lost.

It is quite true that I gave this patient the iodide of potassium with three grains of blue pill three times a day from the first, but, in addition, I ordered two leeches to be applied to each temple every third day, to be repeated three times, and, after the bleeding, cold spirit and water was frequently applied to the forehead. The last thing before going to bed the feet and legs were immersed in strong mustard and water for ten minutes.

The headache gradually ceased, so that at the end of three weeks his nights were not in this respect disturbed. The mustard baths were discontinued. At the end of six weeks he was in every way so much improved that I had the greatest trouble to keep him from business, but I succeeded in getting him away to the Isle of Wight for two months. He was ordered to discontinue the pills, but to continue taking the iodide of potassium. I am happy to say that his malady has subsided. I say subsided only, because I am quite fearful of another outbreak.

INTERESTING CASE OF IMPERFORATE HYMEN.

By GEORGE KILPATRICK GIVEN,
Medical Officer, Gorton Union Infirmary and Dispensary.

On Dec. 3, 1877, I was called upon to visit Miss Annie A., an extremely fine-looking and well-nourished young girl, aged 17 years all but two months. I found her to be in all respects healthy, save and except that, up to this date, she had never menstruated. Her cheeks were quite rosy, and in short, I was at first not a little surprised on being told she was the patient I had been brought to see. On hearing a statement of the girl's case, I had her put to bed, when, on examining the abdomen, I found it to be greatly swollen and extremely hard, almost, if indeed not quite, as hard as one may feel the abdomen in advanced pregnancy. The mother, who was standing by me whilst engaged in making my examination, seemed, upon my noting this fact, to yield herself to deep distress, and evidently had begun to feel quite satisfied that it was all up with poor Annie, so far at least as her virginity and virtue were concerned. I should, perhaps, have mentioned that this girl had lately been accustomed to experience little periodical attacks of, well, not exactly sickness, for she on none of those occasions felt compelled to take her bed, or even for a day to quit her usual avocations, but a sort of *malaise*, which briefly passed away, and always left her quite "herself again." On completing my examination of the abdomen, I next had patient placed in the obstetric position, and soon discovered that there was a tense and hard, and fluctuating bag (the term by which I can most faithfully describe it), feeling exactly like the bag of liquor amnii as we do sometimes feel it "when a pain is on," projecting from the labia. Running then my index finger round the mass, I vainly sought therewith to penetrate its bordering sulcus, and quickly, therefore, saw the nature of the case I had before me. I found the entrance to the genital canal most perfectly occluded, and saw, of course, that the projecting bag was nothing other than a doubtless greatly *stretched* but yet *unbroken* hymen. This discovery being made, my next proceeding was to breathe a word of consolation to the nigh demented mother, and then I plunged a keen scalpel into the mass, whence, instantaneously, there gushed an inky, tarry torrent of evidently long imprisoned menstrual fluid. Palpation now revealed the act that the abdominal hardness and distension had completely gone, had vanished as by magic, and not a trace of them was left behind. No bad symptom followed, and ever since, I'm told, the girl regularly menstruates as others do.

I place this case on record, since I consider it to be one of interest to the practising physician, and for the following, amongst other reasons, viz. :—

1. The age reached before relief was sought, nor do I think that in this case relief would have been sought even yet, but that the girl's friends had come to think her pregnant.

2. It affords additional and positive proof that retention of the menses for a lengthened period is quite compatible with perfect health.

3. That the rule, of which we are all aware, laid down by certain authors regarding the danger connected with operating under circumstances such as these, does not by any means hold good in every case.

4. That the question of the hymen's integrity should be always borne in mind when we are called upon to deal with certain forms of amenorrhœa.

The annual rates of mortality in the four principal cities of the United Kingdom last week were 22 in London, 22 in Edinburgh, 24 in Glasgow, and 31 in Dublin, per 1,000 of the population. Of the other large towns, Portsmouth gave the most favourable return with 17, and Plymouth the highest death-rate, viz., 35 per 1,000.

Clinical Records.

ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.

A Case of Sarcoma of the Choroid.—Enucleation.—Great Danger from Excessive Narcosis During the Operation.—Recovery.

Under the care of Mr. SPENCER WATSON.

Ellen S., æt. 7, was brought to the South London Ophthalmic Hospital in April, 1875, with a staphylomatous protrusion of the upper region of the sclerotic, of the size of a small bean. The whole eyeball is enlarged and distended, and the corneal region thrust downwards and forwards, the upper eyelid being somewhat distended, and giving the aspect of general protrusion. The movements of the globe are somewhat limited in the upwards and outwards directions, but the orbital tissues themselves are not sensibly enlarged or protruded. There is slight perception of light, but no distinct vision. The ophthalmoscope gives no view of the fundus, but an obscure dull reflex.

History.—The child's mother is a healthy woman, with three children. She has lost two or three others, and her attendant, Dr. Scott, of Kennington Road, thinks that there is some syphilitic taint in the family. The patient, Ellen S., has been delicate for the last three years, and has lost flesh and appetite. She had nothing wrong with her eye till a month before admission (April 30), when it became inflamed and bloodshot, but she could see with it tolerably well till a fortnight ago, when it was lanced by Dr. Deeping, of Southend, on account of the severe pain she was suffering. A little blood escaped from the puncture, and the pain was relieved.

May 1st.—The staphyloma being evidently on the increase, Mr. Watson tapped it by means of a fine cataract needle. A small quantity of thin serum escaped, and this was followed by a bead of vitreous.

May 7th.—The eyeball having refilled and become tense and painful, it was determined to repeat the tapping, and for this purpose the speculum was introduced, when the globe gave way suddenly, and a large prolapse of vitreous took place. The child being now under the influence of chloroform, it was decided to enucleate the globe. This was done in the usual way. The removal of the globe was followed by very free bleeding, and the patient became suddenly faint and collapsed. She was immediately inverted by raising her legs, and suspending her with her head downwards, at the same time drawing the tongue forwards. A deep inspiration followed, and natural breathing and healthy colour was restored.

On November 5th, 1875, there had been no bad symptoms, and an artificial eye had been fitted to the socket. The child's health continued very feeble.

July 3rd, 1877.—There had been, from her father's account, a constant discharge from the eye. It is probable however, that this was merely conjunctival, and up to this date there seems to be no evidence of any return of the disease.

Examination of the Eyeball After Removal.

After cutting through the anterior part along the ciliary region, two nodular masses were discovered lying outside the choroid, and continuous one with the other by a constricted isthmus stretching across the optic nerve. These tumours were adherent on the one side to the sclerotic, and also to that part of the choroid which lies near the optic nerve. They were, when fresh, of a bright yellow colour, and so soft that it was impossible to make a section, being in fact, semi-fluid towards their centres.

After hardening for some weeks in Müller's solution, the growths were examined by Mr. Nettleship, who gives the following description of their structure and relations:

"The choroid seems to be the seat of the growth, which

is however thickest and largest at the back of the eye, around the optic nerve entrance. There are, however, some large—more or less separate—hillocks of the growth in the more anterior portions of the choroid. There does not seem to be any retina left. The optic nerve is not obviously altered, and it is loose in its sheath as usual. The growth is intimately adherent to the sclerotic, appearing, indeed, quite continuous with its structure. Microscopically, it consists of round, or roundly-oval cells of rather large size, with one, sometimes two, nuclei. There are, besides, many apparently free nuclei, in size and refraction resembling those contained in the large cells, and also cells of small size nearly filled by the contained nucleus. In one part of one section the growth showing all these characters is well seen infiltrating the remains of the stroma of the choroid. In some parts a few well-marked large spindle-shaped cells occur, but they are not numerous, and may, perhaps, be only the remnants of the proper choroidal tissue. The sections of the optic nerve do not give any evidence of invasion by the morbid growth. Whether the growth began in the retina as a glioma or not, it certainly has not now the characters of glioma, but of round-celled horoidal sarcoma, in which the majority of the cells are a good deal larger than those of glioma."

From the above description it is probable that the growth originated in the outer layer of the choroid, and that it invaded and infiltrated the sclerotic at an early stage.

SAINT ANTOINE HOSPITAL, PARIS.

Lesion of the surface of the Cerebrum, extending into the Centrum Ovale—Epileptiform Convulsions—Hemiplegia.

Reported by C. MAYGRIER, M.D.

A. GENEVIEVE, æt. 30, was admitted to the above-named hospital, Oct. 17, 1877. Her occupation in life was doubtful, she was probably a prostitute. She was not addicted to drinking, and denied ever having suffered from syphilis. She had complained of ill-health for about eighteen months, tracing its origin to some blows she had received on the left side of the head. She had felt pain in this place, and had since been liable to epileptiform seizures, coming on especially at night. For about the last four months she noticed her right side was weaker than her left; this paralysis, at first only slightly marked, progressively increased.

On admission, she presented the following symptoms—acute cephalalgia, localised to left side of head, hemiparesis of all the right side of body. The right leg was much weaker than the left. She walked *en fachant*. The right arm hung almost inert, yet she could raise it as high as the face; the features of the right half of the face were altered, but the orbicularis palpebrarum had not lost its action. The tongue was slightly turned from the paralysed side, speech a little embarrassed; intelligence clear, and the memory unaffected; sensibility unimpaired in paralysed parts. General health was good, the urine normal, not containing either sugar or albumen.

The convulsive seizures were noticed, from the first day of her admission; they occurred about three or four times in the twenty-four hours, chiefly at night. Up to November 25, her condition did not vary, but after that date, the attacks became more frequent—she had four on the night of the 25-26th November, four on the night of the 26-27th. The following days the seizures became more frequent.

During these attacks the patient presented the following characteristics:—

For two or three seconds *tonic* spasms occurred which became *clonic*, especially on the paralysed side.

The thumb lay in the palm of the hand embraced by the fingers, the head was turned to the right—the hemiplegic side. Occasionally, the muscles of the face worked convulsively, especially on the right side, without the other parts of the body sharing in the disturbance. She died comatose on the morning of November 30th.

Autopsy.—The abdominal viscera were healthy, the lungs and heart normal, some atheromatous deposits were found on the aorta, stopping short at the sigmoid valves, which were free from them. At some points small aneurismal dilatations were already formed.

Cranium.—The dura mater was healthy, the pia mater congested, it peeled off easily, except at one point, on the external surface of the left hemisphere, where it was of a greyish colour, thick and resisting, and intimately adhering, to the extent of about a 5s. piece. This point corresponded exactly with the inferior part of the frontal and ascending parietal convolutions, and with the middle of the fissure of Sylvius, the edges of which were glued together. On a vertical incision, it was seen that the lesion only affected the grey substance alone in its two lower thirds, but towards the upper part it extended into that portion of the *centrum ovale*, called after the nomenclature of M. Pitrés, by the name of the middle fronto-parietal fascia. This lesion presented all the characters of a cicatrix, the pia mater was here blended with the cerebral substance. If we dismiss the idea of a softened and cicatrised gumma, the most reasonable hypothesis was that the lesion was traumatic. The patient denied all specific contamination, and there was no trace in any part of the body of syphilis.

Remarks.—This case is particularly interesting, as it perfectly accords with recent facts on localisation of the cerebral surface and of the *centrum ovale*. The lesion at the foot of the frontal, and ascending, parietal convolutions accounted for the facial paralysis, whilst its extension into portion of the *centrum ovale* was sufficient to account for the paralysis of the limbs observed during life.

Transactions of Societies.

MEDICAL SOCIETY OF LONDON.

AT the meeting of this Society on the 18th inst., Professor ERASMUS WILSON, F.R.S., President, in the chair, Mr. ALLINGHAM proposed, and Mr. ADAMS seconded that a vote of thanks be given to the silver medallist, Dr. Godson, on his retirement from the office of hon. secretary, and to the other retiring members of the Council. The vote was carried by acclamation.

Mr. WM. ADAMS exhibited to the Society

A NEW SHOE FOR THE TREATMENT OF TALIPES EQUINO-VARUS, ETC.,

by the use of which many of these cases may be cured more perfectly and in a shorter time than by the instruments generally in use.

Mr. ADAMS considered that the instrument generally in use, the so-called Scarpa's shoe, was admirably adapted to the treatment of talipes equinus, in which deformity the foot moved as a whole from a single centre of motion, viz., the ankle-joint; but a great error was committed when this apparatus was used for the treatment of talipes equino-varus, or for varus. In all the more complex distortions such as equino-varus, varus, and severe valgus, the foot no longer moves as a whole from one common centre of motion, but it moves in two portions from two distinct centres of motion, viz., the ankle-joint, and the transverse tarsal, or as it is sometimes called the medio-tarsal, joint in front of the astragalus and os calcis. It is of the utmost importance to consider the direction in which the anterior and the posterior portions of the foot move from these two great centres. At the ankle-joint we have only the simple movement of flexion and extension; but at the transverse tarsal joint, which partakes more of the ball-and-socket character, the anterior portion of the foot is capable of being moved in several directions. In equino-varus, and in varus, the anterior portion of the foot is inverted, rotated inwards, and flexed, so that the foot is bent upon itself in the direction of its length; and in severe cases of talipes valgus the anterior portion of the foot is rotated outwards. It is obvious, therefore, that the instrument used to correct these distortions should be subdivided like the foot into two portions, moving like the foot from two distinct centres of motion, and that each portion should be capable of moving in the same directions as the portion of the foot to which it is adapted. The mechanical centres of motion must also be made to correspond as nearly as possible to the anatomical centres of motion. It is with these fixed ideas that Mr. Adams had gradually improved the instrument which we still call the Scarpa's shoe, and the latest improvements are shown in the instrument exhibited to the Society. It has been made, under his direction, by Mr. Ernst, of Charlotte Street, Fitzroy Square. In this improved Scarpa's shoe, the sole plate is divided into two portions by a joint correspond-

ing to the transverse tarsal joint, and the anterior portion can be moved in various directions by three cog-wheels, or rack-and-pinion movements in the sole plate; the movement of inversion and eversion is regulated at one, that of flexion and extension at another, and rotation at the third, so that the anterior portion of the sole plate can be moved in any of these directions, the mechanical thus corresponding to the anatomical centres of motion in the production of the deformity.

THE OBLITERATION OF PORT-WINE MARK.

Mr. BALMANNO SQUIRE read notes of two cases of port-wine mark treated with a view to obliterating the mark without scar. The one case was that of a man, aged thirty; the other that of a woman aged fifty-five. In both the port-wine mark was confined to the right half of the face, and in each case treatment was carried on long enough to produce nearly complete obliteration of the mark. Scarification was adopted in both cases by means of parallel incisions with a frozen scalpel, the skin also being frozen by means of the ether spray; the cuts involved the entire thickness of the skin, and were made about one-sixteenth of an inch apart, and as soon as these had healed (within three or four days) further parallel incisions were made obliquely in the same direction, and so on with a series of operations. This procedure gradually resulted in the fading of the port-wine mark, and its final complete obliteration without leaving any scar. Mr. Squire showed drawings of these cases, and of an instrument he had devised for executing a series of incisions at one stroke. It was a scalpel with sixteen parallel blades, placed so closely together that eighteen of them measured only half-on-inch across. He also described an apparatus, consisting of a number of parallel needles fixed in a plaster of paris handle, so that the handle contained thirty-six needle-points in the half-inch square. These should only be heated to a black heat on their insertion into the skin, for if heated to redness they produced complete sloughing of the entire area of skin operated on.

The PRESIDENT said that the operation was obviously as yet only in its infancy, but the process of linear scarification, as proposed by Mr. Squire, appeared to him to promise good results. Certainly no other satisfactory mode of dealing with port-wine marks had as yet been proposed.

Mr. Malcolm Morris, Mr. Wordsworth, and Mr. Davey also made a few remarks, after which

Mr. SQUIRE replied that, in order to succeed in effecting neatly close parallel incisions, some practice in pencil or in pen-and-ink drawings was a considerable advantage, and that those practitioners who happened to have this kind of training would find but little difficulty in the matter. However, the multiple scarifier he had devised would effectually dispense with the necessity for that kind of accomplishment. He had tried multiple linear scarification in lupus, but preferred the results he had obtained in that disease by erasion with a minute sharp steel spoon; scarification of any kind, as applied to port-wine mark, was, he believed, as yet untrodden ground.

THE ACTION OF MALARIA.

Dr. SULLIVAN then read a paper on the action of malaria on the human organism, advocating the theory that to nerve paralysis, through the action of this poison, must be attributed, not alone the phenomena manifested during a paroxysm, but also the sequel of the intermittent fever. The author explained, by means of a diagram, the special venous circulation between the spleen, stomach, pancreas, and liver, together with the peculiar function of the spleen destined to supply to the glands of the stomach the materials necessary for their secretion, deducing therefrom the opinion that whatever tends, like the poison of malaria, to impair the function or the texture of the spleen (an organ which, as a part of the lymphatic apparatus, acts so important a part in the formation of the blood, and in the process of nutrition), must affect greatly the function of digestion.

DUBLIN OBSTETRICAL SOCIETY.

THE Fourth Meeting of the Session was held on Saturday, February 9th, 1877, Dr. S. M. MACSWINEY, Vice-President, in the chair.

THE LATE DR. FLEETWOOD CHURCHILL.

M'CLINTOCK said—Before the Society proceeds to the business of the evening, I would ask your permission, Sir, to move a resolution. It is a very painful duty to me to have to move a resolution to the same purport and of the same nature as that which I proposed at the last meeting of the Society. It is always a painful and a distressing thing where we have to bring forward a resolution and allude to the decease of a fellow member, but it is peculiarly so on the present occasion, when the resolution that I am about to move has reference to the late Dr. Churchill, who was known, esteemed, respected, and beloved, I believe, by every member of this Society, and who was endeared to me by twenty-five years of warm friendship. I believe, Sir, that, in this Society, it would be quite unnecessary and mere affectation were I to dilate upon his claims, or upon his professional character. His reputation as an obstetric writer was of the highest degree; it was world-wide. For nearly a quarter of a century his works on midwifery and diseases of women, and on the diseases of children were the text-books universally quoted and referred to, both in the hands of students and practitioners. Those works were re-published in America, and were also translated into some of the European languages. As a practitioner, Dr. Churchill was known to us all. There are few members of this Society who have not at one time or another had occasion to call into requisition his experience and his judgment. As a man, as a gentleman, as a member of the medical profession, he was, I need hardly say, a man of unsullied reputation. He maintained the honour and dignity of our profession in every relation of life, and in every position. In addition to this, as you all know, he was a man of very cultivated understanding, and of a very enlarged Christianity of heart. I need say no more to commend this resolution which has been drawn up, and which I am about to submit to the support of the Society. —"Resolved: That we place on record our sincere regret at the decease of a distinguished fellow member, Dr. Churchill, who, from the foundation of the Society until the time of his death, embracing a period of nearly forty years, never ceased to take an active and a warm interest in its welfare, and who, by his own professional eminence, as well as the moral weight of his character, contributed in no small degree to the reputation of our Society." I have great pleasure in submitting that resolution.

Dr. DENHAM seconded the resolution, which, he said, was so ably proposed by Dr. M'Clintock.

The CHAIRMAN—This is the only tribute which this Society can now pay to the memory of their late President, who was so endeared to every member of the Society, and it is put to the Society in words so appropriate and so graceful by his long-timed friend that another word would be misplaced respecting it.

The resolution was then passed in solemn silence.

CONGENITAL FRACTURE.

Dr. SMYLY exhibited the head of a fœtus which presented a spoon-shaped fracture on the left side of the frontal bone. Those injuries were sufficiently uncommon from any cause, but were especially rare where the fracture took place by the unaided contractions of the uterus, as they were generally caused by instrumental delivery, the bone being dragged past the promontory of the sacrum. It was the woman's seventh pregnancy. She had previously had an abortion in 1876, and again became pregnant last year. Her last menstruation was on the 7th of April last, and the child whose head he exhibited was born on the 23rd of December, so that it was probably an eight months' fœtus. Labour commenced the day previously, on the 22nd of December, at 4 o'clock in the morning, and the membranes gave way at 3 o'clock that afternoon. She was seen shortly afterwards, and it was found that she was in the second stage, the os being fully dilated, but the head was still above the brim. With the exception of that there was nothing abnormal. On examining the patient again at 9 o'clock that evening, three or four loops of the cord were found in the vagina, but it was quite pulseless. The child being dead, it was considered advisable to let the labour go on of itself. At half-past one o'clock the next morning it was found that no advance had been made since 4 o'clock the previous afternoon. The head at this time had not entered the brim of the pelvis. While the examination was being made at one o'clock in the morning, the head came down "with a jerk," and the child was immediately afterwards born, though there was some difficulty in extracting the shoulders. The child was of course dead, but apparently it had not been so for a very long time. There was no scalp tumour. The fracture was situated in an uncommon position, for those

fractures usually occurred in the anterior portion of the parietal bone, and rarely on the frontal bone.

OVARIOTOMY.

Dr. ATTHILL exhibited an ovarian cyst removed by him that day from a patient in the Rotundo Hospital. The patient was aged only 18 years, and came under his care about four months previously, at which time he diagnosed the existence of an ovarian cyst of small size, evidently unilocular and free from adhesions. Taking into account its condition, then, he was indisposed to operate, and he postponed doing so from time to time, being unwilling to risk the life of the patient till the symptoms became aggravated. Of late, however, she had began to suffer considerable pain, and of rather a perplexing character, for though the pain was referred to the tumour, there were no symptoms whatsoever of peritonitis. There was no pain, there were no rigors; the frequent occurrence of pain, coupled with the urgent wishes of the patient and her relatives, induced him to operate. The operation in its steps was exceedingly simple and easy. The cyst was exposed without difficulty, and it proved, as already diagnosed, to be free from adhesions, and to be unilocular. He was, however, somewhat surprised on introducing a trochar, to find that there came nothing but pure pus, in fact the cyst was a suppurating one. In removing the tumour but a drachm or two of pus escaped into the abdominal cavity. The cyst having been turned out, the pedicle was secured with a silk ligature, and returned into the cavity of the abdomen. The cyst had not yet been opened; portions of the pus having escaped into the abdomen, had increased the risk, but it was quite evident that the patient would have succumbed before long to the disease if she had not been operated upon. The cyst was exceedingly small, the quantity contained in it being not much more than a pint and a-half. It appeared to be nearly free from solid matter, though there was a certain amount in it. The patient, he was happy to say, up to the present moment, was in a very satisfactory condition. There had been no vomiting whatever. The pulse was about 110, and her temperature 101°, and he was very hopeful that she might make a fair recovery.

The adjourned discussion on Dr. M'CLINTOCK'S paper on

TRANSFUSION

was then commenced.

Dr. ROBERT MCDONNELL, F.R.S. (President of the College of Surgeons), asked the permission of the Society, prior to the discussion, to show his transfusion apparatus, which he did not happen to have with him on the last night of the Society's meeting. As the operation was essentially one of emergency the case should contain everything that the operator required, and he was provided even with candles in order to ensure having proper light. The only thing needed over and above what was contained in the case was warm water and an ordinary jug—appliances which were generally to be found in the house of the humblest person. The first thing to be done was to secure the arm of the patient who was going to be bled. That was so rarely done now a days that any young gentlemen who were thinking of transfusing would have to commence by learning how to bleed a patient. To facilitate matters he had a small garter which he placed round the arm above the point where the vein was to be opened, in order to make the vein full. The lancet having been applied the blood was drawn into a clean warm vessel, and while the blood was passing into it it was stirred with a clean glass stirring-rod. It took a very short time, indeed, for the blood to commence to coagulate upon the end of the pipe, so that caution had to be exercised. The blood had then to be strained through a piece of muslin—a clean pocket-handkerchief would do—into a vessel which was perfectly clean; great attention had to be paid to these things. Then the papette which sucked up the blood from the last-mentioned vessel was filled and placed in a jug of water warmed to about 100° of heat. That formed the first part of the operation—drawing the blood, defibrinating it, and filling the papette, and placing it in a jug of hot water. With regard to the papette, he did not believe it was generally necessary to use so much as even filled the papette, and the most successful cases had been those in which small quantities of blood had been used. About half or three-quarters as much as filled the vessel was generally enough. In the middle of the india-rubber-tube leading from the papette there was a little bulb. When the blood filled that little bulb, by squeezing it the operator was enabled to simulate the pulsations of the heart in driving the blood into the patient. The next point of the operation required some nicety, as the patient was quite bloodless, and the difficulty was sometimes to find the vein near the elbow. When the vein was found, it was raised by a pair of forceps and a small hook applied in order to fix it so that the vein shall not escape, and that the operator may not lose sight of it. A small opening was then made in the vein sideways. There is not the slightest necessity for haste all this time. The assistant then handed the probe-point at the end of the india-rubber-tube, and that probe-point, which extended a considerable way beyond the eye of the instrument, was introduced into the opening made in the patient's vein, and passed up until the eye was well in the vein. Pressing the little bulb at the india-rubber-tube when they knew that the air was expelled—indeed, generally speaking, its own weight was sufficient to allow it to flow—forced in the blood. Those were the steps of the operation to which he desired to direct attention before the discussion commenced.

Mr. MACAN said, from what they had heard, it was obvious that the cases of transfusion which did best were those which required the least blood injected. The object of transfusion was not to replace the blood lost, but rather to act as a stimulant on the brain and heart. There was no danger in replacing the whole of the blood lost by transfusion, but it was practically found to be useless, and Dr. McDonnell had stated that the most brilliant results were in those cases which required very little blood. Speaking of the bandaging of the limbs, that was called auto-infusion now a days, and was most applicable, and had most brilliant results in those cases where there had been sufficient loss of blood to paralyse the nerve-centres, and to leave the blood in the body badly distributed. Bleeding the veins of the abdomen and the veins of the extremities, if the limbs were bandaged, and if friction was made over the abdomen, blood was sent up to the heart and the patient still lived. Of course, transfusion might be driven to the utmost extremity, and for that they had only to go to Germany, where to counteract the anæmia caused by chloroform the operation of transfusion would be undertaken. There was some doubt about the question of the use of defibrinated blood, as it was considered not to have the same effect as ordinary blood, and it was not considered the best practice to transfuse defibrinated blood if it was intended to cause contraction of the uterus and to prevent hæmorrhage going on. He could only say that by keeping the patient's head very low, which had always been done in the Rotundo Hospital, to a certain extent made up for transfusion, and the injection of ether also made up for the mal-distribution of blood. By means of Esmarch's bandages they could, to a great extent, make up for the loss of blood. He was, however, willing to confess that a case would even go beyond all those means, but it was only after all those means had failed that one should attempt transfusion. He differed with Dr. McDonnell as to the means of transfusing blood, and thought a more practical method could be used than that which he had described. He was also sorry to say that the evidence of the operation, so far as it had been brought into general practice, was very doubtful, and the authorities on the Continent had come to the conclusion that even though it be a successful operation, it would only be able to be used in a very few cases.

Dr. KIDD'S experience of transfusion had not been successful, but he believed that that was not the fault of the operation; he believed it was the fault of the time at which it was performed. He had, in two or three instances, himself performed the operation, but at a time when it was utterly hopeless, so that that was not a fair trial of the operation. He had considered the whole question many times very carefully, and he believed that the method proposed by Dr. McDonnell was the best and safest that had yet been adopted. The danger of coagulum in blood containing the natural proportion of fibrine added, he thought, very materially to the risks of the operation, and if anything was proved in physiology, he thought they might look upon it as an established fact that defibrinated blood was actually sufficient to restore animation and life. To his mind the operation was a safe one, and one that ought to be adopted at an earlier stage than it had been hitherto, and the reason of the many failures had been that the operation had not been practised sufficiently early. The cases that he had seen were ones in which he was called in too late to have any chance of saving the life of the patient. There were so many cases on record of the operation being performed without any evil consequences, that he would not run his patient to the same extent of lowering again as he

had on former occasions. With regard to auto-transfusion the practice of the Coombe Hospital had been not merely to lower the head of the patient, but to elevate the feet and legs. He believed that effected as much as bandaging, and certainly saved a great deal of time.

Dr. DENHAM said the great risk they ran in the operation was in postponing it. He was sure they should seldom wait. He was perfectly satisfied that the operation was perfectly safe in the hands of Dr. McDonnell, and he was sure the success of it would be greater if it was undertaken earlier.

Dr. M'SWINEY said that any person having witnessed the mode in which Dr. McDonnell performed the operation, and was acquainted with Roussell's mode of performing the same operation, would be compelled to arrive at the conclusion that the balance of the weight of the argument and of the reasoning was altogether in favour of adopting the Irish, or Dr. McDonnell's, mode of performing the operation. As far as extreme simplicity in the mechanism consistent with the accomplishment of the end in view was concerned, they perceived it was arrived at in Dr. McDonnell's instrument. They also perceived by his mode that the case was a practical application of the very latest and most authoritative expression of physiology on the subject of the part which fibrine played, and the mode in which fibrine was to be regarded as a substance contained in the blood, and finally the success of the operation; and the absence of any collaterally dangerous consequences were even another argument in favour of its adoption. The great objection in Roussell's instrument, that of the tendency of the blood to clot, was removed by the instrument now before the Society. With reference to auto-infusion and the beneficial effects of elevating the body, he (Dr. M'Swiney) desired to recall the fact that more than thirty years ago the late Dr. O'Farrell, of St. Vincent's Hospital, in this city, applied, and published the result of his application of, that principle, when removing an enormous scrotal tumour. The history of that operation would be found recorded in the *Dublin Hospital Gazette* about thirty years ago.

Dr. M'CLINTOCK, in reply, said the result of that discussion had caused him to alter his views as to the operation very much. The case resembled in some of its salient features the original case brought forward in this Society by Dr. Beatty, in which Dr. McDonnell performed transfusion with a remarkably good result, for the patient was in *articulo mortis* when the operation was successfully accomplished. Thirteen hours elapsed from the time of delivery until the operation. That was certainly a very fair trial of the operation, and proved that it was quite equal to the emergency to bring about reaction. But in the case he (Dr. M'Clintock) had, there was a very powerful restorative used, which was not known at the time of Dr. Beatty's case; the subcutaneous injection of sulphuric ether, a restorative agent which was brought under the notice of the Society, he thought, first by Dr. Macan, whose experience of it was indeed strikingly in favour of it as a stimulating and restorative remedy. In his (Dr. M'Clintock's) case he injected thirty or forty minims with certainly the result of bringing about a temporary improvement in the pulse. But that improvement was only temporary, and in a short time the patient lapsed down with all the appearance of approaching dissolution. Three or four minutes after the commencement of the operation of transfusion, there was a distinct improvement in the pulse, as he noticed at the time to Dr. McDonnell. It was not to be wondered at that the result of that case should have made a very great impression in his (Dr. M'Clintock's) mind. There was one point alluded to by Dr. Macan which he (Dr. M'Clintock) occasionally agitated in his own mind, and that was the propriety of resorting to transfusion whilst any bleeding was going on. Was it a remedy to be resorted to before the hæmorrhage was completely suppressed? They knew a patient would bleed as long as there was any blood in the body at all. His own opinion was that he would not be disposed to try transfusion until the suppression had occurred, for he could not understand how transfusion would tend to bring about contraction of the uterus and a stoppage of the hæmorrhage when a direct injection of the perchloride of iron failed to do it. Still the point was an important one, and worthy of being considered

Dr. MCDONNELL concurred with Dr. M'Clintock as to the advisability of not undertaking the operation unless the hæmorrhage had entirely ceased; in fact, that was the first question he asked, when called upon to perform the operation—"Are you certain the hæmorrhage has ceased?" To perform it during the continuance of the hæmorrhage was like trying to lift water with a vessel without any bottom; it would be only calculated to bring the operation into disrepute. With reference to a statement of Dr. Macan, in favour of transferring the blood from artery to vein direct, Dr. McDonnell spoke of the extreme difficulty of performing the operation in that way, and of the great liability of fibrinated blood to clog in the tubes. They were called upon to perform the operation in an emergency when the patient's life was in great danger, and in view of the great importance of the operation, he could not help thinking, from what he had seen, that they were justfied in coming to the conclusion that the operation, if performed with ordinary dexterity, was simple and free from danger. It had not been attended—and he wished to dweli upon this—in any of the instances he had seen with ecchymosis, bloody urine, hæmorrhoids, which were described in some of the German clinical lectures, but he had witnessed this result, that where convalescence had taken place, it had been prompt, complete, and satisfactory. They were, therefore, in a position to say, so far as their experience went, that the operation was not one in which there was any danger worth speaking of, and they, therefore, need not hesitate to have recourse to it if they were able to assure the husband and the relatives that the operation can insure no bad results, and it supplied and fulfilled some of the most important functions, which were desirable to meet with under the trying circumstances in which the surgeon was called upon to act.

The Society shortly afterwards adjourned.

REGISTERED FOR TRANSMISSION ABROAD.

THE
MEDICAL PRESS AND CIRCULAR
Is published every Wednesday morning. Price 5d. Post free, 5½d.

POST FREE TO ANNUAL SUBSCRIBERS £1 2 6
,, IF PAID IN ADVANCE 1 1 0

*** Post-office Orders and Cheques to be drawn in favour of—
A. A. TINDALL, 20 King William Street, Strand, London, W.
A. H. JACOB, 3 Molesworth Street, Dublin.
MACLACHLAN and STEWART, South Bridge, Edinburgh.

SUBSCRIPTIONS FOR FRANCE are received by Messrs. BAILLIERE, Rue Hautefeuille, Paris—post free in advance, £1 3s. 6d. per annum.

SUBSCRIPTIONS FOR THE UNITED STATES are received in New York, by Messrs. WILLMER and ROGERS; Baltimore, by Messrs. KELLY and PIET; Philadelphia, at the *Medical and Surgical Reporter* Office, post free in advance, six and a-half dollars (£1 3s. 6d.) per annum; or direct from the Offices in this country for the same amount, if remitted by International Post-office Order.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, MARCH 27, 1878.

THE ABUSE OF HOSPITAL CHARITY.

Mr. GILBERT contributes to the current number of the *Contemporary Review*, a vigorous article on "The Abuse of Charity in London." He fearlessly denounces and exposes abuses which exist in connection with the five Royal Hospitals "endowed for the benefit of the sick, aged and distracted poor of the city and suburbs thereof." The hospitals in question are Christ's, Bethlem, Bridewell, St. Bartholomew's, and St. Thomas's. With the three first-named the medical profession have little to do, and are indeed interested only to the extent of lamenting that the large funds of these institutions are greatly perverted and

extravagantly administered. Of Bethlem, it is true that at one time it promised to become a school for the study of mental disease, but this expectation has not been realised, and of late years it has quite subsided into an asylum for those who can afford to pay for the care and skill bestowed upon them. It is impossible to believe, however, that the vast income of nearly £30,000 a year of this hospital, can be legitimately expended upon the 270 insane inmates annually treated in its wards. We can only say it must be managed in a very different way from a kindred Asylum at Caterham, where 1,800 patients are lodged at a cost to the ratepayers of £6,361 per annum, or at Fisherton, where the criminal class of insane are well cared for at a cost not exceeding eleven shillings per head per week.

The hospitals which, however, more immediately concern the profession are those of St. Bartholomew's and St. Thomas's; and these, Mr. Gilbert shows, are open to a charge of mismanagement, and a perversion of funds quite beside the original intention of their founders. By their charters it appears they were never intended solely for the treatment of disease, but were established to receive "all infectious and incurable cases," as well as "for sheltering the aged and impotent." Beyond this they were meant to be asylums for lying-in women, and a clause in the charter of St. Bartholomew's ordains "that in case of the death of the mother the child shall be maintained by the hospital authorities until it is seven years of age, and then transferred to the Blue-coat School." The gross value of the capitalised assets of the two hospitals is fully equal to five millions sterling, whilst the annual income derived by St. Bartholomew's must be quite £60,000, and that of St. Thomas's, £42,000. Mr. Gilbert protests against the lavish outlay incurred in rebuilding the latter, which cost not less than £800 per bed. "Indeed," he adds, "it has been estimated that had the present inmates of St. Thomas's Hospital been located in mansions in Belgrave Square, they would have been accommodated at less than half the house rent they incur in the present hospital." It is generally admitted that this hospital, as a whole, is a complete failure. Although intended as a model of what a medical charity should be, it can in no way be accepted as a pattern for similar institutions, or be thought worthy of imitation. The inconvenience of its position Mr. Gilbert believes is a serious drawback to its usefulness. A costly executive, and extravagant administration, and a niggardly recognition of the services of the medical staff, are the chief characteristics of the Royal Hospital of St. Thomas's; but that the locality of St. Bartholomew's and St. Thomas's deprives the poor of the Metropolis of much of the advantages which might be derived from them is very questionable. It is the boast of the treasurers of these hospitals that last year the former relieved upwards of 117,000 outdoor patients, and the latter about 50,000, a very large proportion of whom, it is well known, were not fit objects of charity at all, and who were not in the least deterred by distance from a dishonest participation in charity doles. There is, however, one blot on hospital management which applies to all alike, but which Mr. Gilbert in no way touches upon, it is the great abuse of the out-patient's department. The scandalous abuse of hospitals is a serious evil, calling for redress, since it demoralises the poor and robs the profession.

The general and special hospitals supported by voluntary contributions spend upwards of half a million sterling annually. Most of them admit patients without inquiry and some on governors' letters. They have all greatly assisted to destroy thrift and independence among the working-classes, and although the Poor-law has thirty-eight free dispensaries for paupers distributed over London, and the Metropolitan Board has infirmaries and hospitals for the same class of persons and for the reception of those suffering from infectious diseases, no account whatever is taken of this, and, consequently, no effort is made to obtain a small payment from out-patients, and which would help to promote independence of feeling and meet the cost of hospital maintenance. In the solitary case of the Lock Hospital this has been done, and with advantage to the institution. The same remarks equally apply to free or "improvident" dispensaries, of which thirty-three receive nearly £27,000 a year, and the five surgical appliances societies receiving about £10,000 a year, although by law it is provided that all really deserving poor persons shall be supplied *free* at the Poor-law Infirmaries.

Another class of institutions in connection with hospital maintenance requires jealous care—the Nursing. There are thirteen nursing institutions, spending upwards of £9,000, exclusive of the large sums derived from hospitals, and which is found to be of a very costly character. Can any system be said to be faultless that converts every fourth person into a pauper? for in London a million of people obtain gratuitous medical relief, and renders the existence of provident institutions well nigh impossible.

Mr. Gilbert, with all his acuteness, does not quite see how important it is, in a public point of view, that men who have become eminent in their profession shall be in a position to train up younger men to follow them, and relieve them of anxious duties, and without whom sufferers in hospital wards must languish the greater part of the twenty-four hours. There must be resident officers ready and willing to devote every hour of the day to the work of alleviating disease, and ready to meet emergencies. It would be of little use to maintain hospitals if we were unable to provide efficient physicians and surgeons able to undertake the duty and care of the sick, and willing to do so for the love of God. We might just as well expect to see our ironclads steam out and fight our battles without engineers and officers to direct them. Mr. Gilbert's article is of sufficient interest to demand something more than a passing notice.

NURSERIES OF TYPHOID FEVER (AND DIPHTHERIA?)

In the third appendix of the last Annual Medical Report of the Local Government Board there is an abstract of the medical inspections made in 1876 with regard to the incidence of disease in particular places, and to certain questions concerning the local sanitary administration of those places. Although the tabulated abstract occupies only four or five pages of the Report it is, nevertheless, an instructive one, and suggestive of reflections which will

no doubt be turned to practical account by all those members of the profession who are specially interested in the origin and diffusion of zymotic diseases.

The area of inquiry extended to twenty-one different localities, and in these tables we have a brief report both of their respective sanitary condition and of the epidemics by which they had been respectively visited. It was, in fact, the extraordinary prevalence of disease in these localities which gave rise to the Government inquiry, the attention of the Government having been called to the subject either by the Registrar-General's Returns, by the medical officers of health, or by the local authorities. The epidemic which seems to have been most constantly prevalent in connection with insanitary conditions was that of *enteric fever*. This fever was of frequent occurrence in thirteen of the localities visited, namely, at Chalvey (Bucks), Eagley and Bolton (Lancashire), Great Coggeshall (Essex), Hanwell, Llanelly (Brecon), Ludlow (Shropshire), Machynlleth (Montgomeryshire), Penkridge (Staffordshire), Heolfach (Glamorgan), Royston (Herts), Tideswell (Derbyshire), and one or two other districts. Now, in all these places the conditions which gave rise to the prevalence of typhoid fever were very much the same,—the sewerage and drainage either altogether absent or remarkably defective, filthy privies and cess-pits, pollution of wells from neighbouring privies and pigsties, ill-constructed and ill-managed closets, general prevalence of slop and excremental nuisances, dilapidated and filthy dwellings, an intermitting water-service allowing of suction of foul air into water-pipes, cess-pools and wells intermingled in porous soil, subsoil saturated with water contaminated with sewage, and other sources of the excremental fouling of air, earth, or water; these were the circumstances which most commonly characterised the sanitary state of those localities in which typhoid fever was unusually prevalent. In two localities the origin and spread of the fever were distinctly traced to an infected milk supply. Thus, there were simultaneous outbursts of enteric fever in Eagley and Bolton in connection with the milk service of a particular dairy—dairy-water obtained from a brook, the course and banks of which had been largely fouled by human excrements. At Great Coggeshall, also, an epidemic of enteric fever spread in the first instance through the agency of infected milk, and subsequently through the generally defective sanitary arrangements of the town.

Blackwater (Hants), Portsmouth and Redruth (Cornwall) were visited by a severe epidemic of *scarlet fever;* and of all these places it is reported that not only did local sanitary conditions favour the spread of the disease, but there was great default on the part of the sanitary authorities in making provision for the isolation of the persons affected.

Passing over one or two other facts reported by the Government Inspectors, we come to the consideration of several outbreaks of *diphtheria* which respectively occurred in certain of these ill-reputed districts, but the etiology of which is by no means so clear as that of the outbreaks of enteric fever. Diphtheria, in its sporadic forms, is supposed by some to originate in unfavourable hygienic conditions, especially in drainage emanations; whereas, antihygienic conditions do not seem to increase the frequency of the contagious form. By no particular season, by no particular locality, by no particular states of the atmosphere do the origin or progress of an epidemic appear to be influenced. In towns and hamlets, observes Trousseau, which are remarkable for their salubrity, "I saw diphtheria raging with excessive violence, whilst some villages situated in the midst of marshes, remained exempt from the scourge." The same circumstance was noticed by Bretonneau, and has since been noticed by many other observers. Now, this opinion appears to be further corroborated by the Report before us. It is true that some of the localities in which diphtheria broke out were remarkable for their defective sanitary arrangements, but it does not follow from this fact that there was any causal connection between the epidemic and the causes assigned to it. It might have been a coincidence and nothing more; and that this was the case is the more probable when we find that some of the epidemics occurred in places, the sanitary condition of which was fairly good. Diphtheria had been prevalent in eight out of the twenty-one districts visited by the Government Inspectors, but in two out of the eight cases there was nothing to account for the appearance of the disease. Thus, at Ash, in Kent, there was a severe and fatal outbreak of diphtheria at an isolated farm-house. Very minute inquiry was made respecting the source of the disease, but without any positive result. Again, at Horningsham (Wilts), diphtheria was fatally prevalent, but the sanitary condition of the village was good, and there was no evidence of the causation and diffusion of the disease. At the same time it is not improbable that bad hygienic conditions may have something to do in spreading, if not in originating, diphtheria. In this Report we find that, while diphtheria was endemic in Phillack, a village, the drainage and water-supply of which were very bad, there was no appearance of the disease for five years in the adjacent district of Hayle, the sanitary condition of which was very satisfactory, and in great contrast to that of Phillack. The data, however, furnished by this Report are far from being sufficient to clear up the obscurity in which the etiology of diphtheria is, in some respect, still involved. Much more exact and extended observation must be made before we can be certain as to the share which bad drainage, &c., takes in the production of that disease.

CRIMINAL RESPONSIBILITY.

It is always a good sign when a writer endowed with a little wholesome scepticism, comes forward to throw doubt upon some long cherished opinion or conventional practice of the day. For even should he himself be wrong, he at all events raises a discussion, the effect of which will be either to discover and expose error, or to confirm and uphold the truth. For this reason, we were inclined rather to welcome than to condemn a letter which recently appeared in the *Times*, and in which the writer, "An Asylum Physician," advocated a treatment of lunatic murderers, which many will probably deem more heroic than just. He finds fault with the tendency there is at the present day, to get this class of criminals "acquitted on the ground of insanity;" and asks how the public are to be protected from these pests of society, who often take away lives much more valuable than their own. "Many an insane

man," he observes, "knows well enough the difference between right and wrong, and can calculate the consequences of his acts. An insane patient, under my own care some time ago, who had homicidal inclinations, used to argue deliberately that she could commit murder with impunity, being insane and under certificate. Had she committed murder, a jury would undoubtedly have acquitted her 'on the ground of insanity.' . . . . It is high time, it seems to me, that the growing sympathy for the murderers should be changed for sympathy for their victims. It ought to be laid down and made known, far and wide, that the man who commits murder shall inevitably suffer the penalty of the law, whatever that may be. No plea of insanity ought to be admitted, and no medical experts allowed to present themselves as advocates in the witness-box in criminal cases."

It so happens that this question is also discussed by one of our medical contemporaries, but from a very different standpoint from that taken by the *Times* correspondent. It will, therefore, be convenient to make the respective opinions of these writers the subject of a few remarks, and to consider whether their recommendations would afford further protection to society, without unjustly exposing the criminal lunatic to the extreme penalty of the law, It will be seen that "An Asylum Physician" has his own opinions of the principle which has always guided the judgment of our jurists, namely that of measuring criminal responsibility by the criminal's knowledge of right or wrong. Now, even granting that in cases of this kind, we should be guided by that principle, it must be admitted that the gravest objection should be taken to the above application of it. For the practice of allowing the law to take its course in the case of all murderers alike, whether sane or insane, provided they know what they are about, would be far more unwarrantable than that of acquitting certain desperate criminals on the ground of insanity. It is still more surprising that any "Asylum physician," should go so far to say that no plea of insanity ought to be admitted, and no medical experts allowed as advocates iu the witness-box in criminal cases. Were such a recommendation acted upon, it would undoubtedly lead to many unquestionable lunatics being committed to penal servitude for life, perhaps even hanged. The fact is the criminal's knowledge of right or wrong, is *per se* a very unsafe criterion to go by; but equally objectionable is the criterion adopted by those, who, like our medical contemporary, contend (and justly so) that a person may know he is doing wrong, and yet be unable to resist the impulse to evil, and that "the essential characteristic of 'moral insanity,' properly so called, would seem to be the inhibition of moral control." Were such a definition of moral insanity to hold good in those cases in which the question of criminal responsibility arises, it would follow that there would be few murderers who might not be acquitted on the plea that their crime was committed under uncontrollable impulse.

The question is a large and a difficult one, and can scarcely receive due consideration in this place; but it is evident that neither the old jurist's principle of forming an opinion in such cases, nor the doctrine of "An Asylum Physician," nor the "morbid impulse" theory of modern psychologists, will, to the exclusion of any other criteria, be a safe guide in settling the question of criminal responsibility in any individual case.

Notes on Current Topics.

Differential Diagnosis of Pleuritic Exudations.

According to the observations of Prof. Baccelli, of Rome (*Berlin K. Woch.*, 1877), if, while the ear is kept exactly applied to the walls of the chest, the patient is made to pronounce the word "trenta-tre," almost in the same manner as he would the number "trente-trois," the following facts will be elicited:—

1. The word is clearly heard (even if pronounced in a loud tone) if the pleura contains a large quantity of clear serum, rich, however, in albumen.

2. That this same transmission of the sound is only slightly impeded by the presence of inflammatory effusion which is rich in fibrine.

3. That the word is no longer audible if there is an abundant exudation of sanguineous or purulent fluid.

Large Dose of Chloral.

A case which occurred in the practice of a correspondent of the *Boston Med. and Surg. Journ.*, shows that under some circumstances a large quantity of this drug may be given with impunity. A man, aged 40, of intemperate habits, had been drinking for two weeks, and had had very little sleep. His nervous system was nearly exhausted, and to obtain the desired rest the following mixture was ordered:—Chloral hydrate, ʒx; syr. simp., ʒij; half a teaspoonful at once, to be repeated in an hour if necessary. It turned out, however, that the nurse gave more than was ordered, so that the whole ten drachms were given within ten hours, after which five or six hours of rest were obtained. The next day the patient was quite well, with the exception of a slight headache.

"How to Suppress Quackery."

A writer in the New York *Med. Record* suggests the following remedy:—

In a city like New York, for example, a standing notice should be published in the leading newspapers, by authority of the County Medical Society, stating, in substance, 1st, That no physician in good standing advertises himself in a newspaper, or in any other manner, it being considered derogatory to self-respect, and a violation of the code of medical ethics. 2nd (as is suggested by Dr. Schweig), That the Medical Register, containing a list of all New York physicians in regular standing, can be seen at any prominent drug store. We doubt whether such a plan would be very successful. The numerous long, and *ad captandum* advertisements of the quacks would soon obscure such a notice as that recommended above. Besides, there are so many people who will be gulled, in spite of all the information or protection provided for them—so let them be gulled.

The Action of Alcohol in Fever.

Testi Alberico, says the *Practitioner* (quoting from *Il Raccoglitore*, No. 10, 1877), gives the following results

of his clinical investigations upon the action of alcohol :—

1. That alcohol does not produce any depression of temperature when given in febrile states of the system, though high temperatures do not, *per se*, constitute any contraindication to its use.

2. Alcohol, as long as it remains unaltered in the system, is a powerful dynamic of the vaso-motor nervous system.

3. As a consequence of the changes which alcohol undergoes in the system it indirectly becomes a valuable aliment, whilst it augments the metamorphosis of tissue.

The Vomiting of Pregnancy.

THE *Presse Méd. Belge* notices a method proposed by Dr. Labelski, a physician attached to the Warsaw hospitals, at the Brussels Academy of Medicine, for arresting the incoercible vomiting of pregnancy. As soon as this appears, or even the nausea which usually precedes it, a douche of pulverised ether should be directed by Richardson's spray-producer against the epigastric region and the corresponding part of the vertebral column. The douche should be prolonged for from three to five minutes, or even longer, and repeated every three hours. In obstinate cases it should be alternated with douches of chloroform.

The General Medical Council.

THE Medical Council will meet this year at a much earlier date than heretofore, the 10th of April being the day named. We have always maintained that its meetings were held more to suit the convenience of individual members than the interests of the profession; when parliamentary legislation was already over, or so far advanced as to render nugatory any action of the Council. It gives us pleasure, therefore, to record this sensible alteration, and to express a hope that one of the first acts of the Council will be, to endeavour to induce the government to so far amend the "New Medical Reform Bill" of the Duke of Richmond, as to make it a little less ridiculous in the eyes of the profession, and a little more protective of the public interest. In such matters we must be content with small mercies, and if the action of the Medical Council shall tend to this end, it will have furnished at least a valid *raison d'etre*.

The composition of the Council has not undergone many changes since last year. The Faculty of Physicians and Surgeon, Glasgow, will have to elect another representative, *vice* Dr. Fleming, who has sent in his resignation, after a period of fourteen years' membership. The Crown nominees, Drs. Hudson and Fergus, will occupy the chairs of the late Dr. Stokes, of Dublin, and Prof. Lister, of Edinburgh, respectively; beyond these no further changes are anticipated.

The Famines of the World.

AT the monthly meeting of the Statistical Society last week, an interesting paper was read by Mr. Walford, on "Famines—Past and Present." The principal feature was a table containing dates and details of some 350 famines, now prepared for the first time. The famines of India, of which there have been 34 within the last century, received especial notice, as also the famine now existing in North China. It was stated that the Empire of China had been peculiarly liable to famines, although details concerning them were by no means easy to obtain. The causes of famines were next examined, and these were found to be mainly as follows :—1. Rain, producing floods; 2. Frost; 3. Drought; 4. Other meteorological phenomena, as comets, &c.; 5. Insects, as locusts, grasshoppers, &c., and also vermin; 6. War; 7. Defective agriculture; 8. Defective transport; 9. Legislative interference, as corn laws, &c.; 10. Currency restrictions, lessening the purchasing power of the coin; 11. Speculation, as "engrossing," &c.; 12. Misapplication of grain, whether wilfully or by misadventure. The first five of these were designated "natural" causes of famine, and were dealt with in detail. The artificial causes were deferred for subsequent treatment. It was shown that even in India, "drought" was by no means the exclusive cause of famines. Tables of floods, frosts, &c., were especially prepared, in view, it appeared, of testing the application of the "sun-spot" theory to famines. The author of the paper said he had not been able to trace the supposed sun-spot influence (eleven year periods) at all clearly in his several tables. In the discussion that followed, Sir Arthur Cotton expressed his conviction that improved means of transport was of more importance with reference to Indian famines than irrigation.

Death of Dr. Robert L. MacDonnell.

THE Canadian medical journals announce with much regret the death of Dr. Robert Lea MacDonnell, of Montreal. Born in Dublin, the son of a physician of that city, he received his education there. Soon after his graduation he assumed the assistant editorship of the *Dublin Quarterly Journal*. The Professorship of Institutes of Medicine of McGill College being advertised as vacant, he applied for and obtained it before his arrival in Montreal. He at once assumed a prominent position, and was elected on the staff of the Montreal General Hospital. An apparently brilliant offer reaching him from Toronto, he was induced to throw up his appointments and proceed thither, only, however, to meet with such bitter disappointment that he returned to Montreal after an absence of a few months. In the year 1852 he edited the *Canada Medical Journal*, which ceased to live after a year's existence. As a teacher of clinical medicine he was admittedly one of the best, if indeed not the best, in Canada. Dr. MacDonnell was a graduate of K. & Q.C.P. Dublin, 1844, and M.R.C.S.I., 1841. He was prizeman in surgery at the Richmond Hospital Medical School in the year 1839. In the spring of 1877 the University of Bishop's College granted him the degree of M.D. *honoris causa*, which, had he lived, Convocation would have conferred on him at the meeting which will take place in Montreal in April next. His death was sudden and distressing. At the late Dr. Peltier's funeral, while sitting in his sleigh, waiting to join the funeral *cortège*, a run-away horse, with sleigh attached, came dashing along. He was struck violently by the shaft (it is believed) on the side of the head, and thrown from the sleigh to the ground. He was taken up and conveyed home, regaining complete consciousness before reaching it. He was able to walk into his house, and to answer every question put to him. For twenty-four hours he continued, apparently,

without showing the slightest indication of danger, indeed, improving, when suddenly comatose symptoms came on, and in two brief hours he passed away. A *post-mortem* examination revealed most extensive fracture at the base of the brain.

The Disinfection of the Battle Fields.

With the approach of warmer weather, the serious attention of sanitary authorities on the Continent, especially in Austria and Turkey, has been drawn to the accumulation of corpses on the battle fields of Bulgaria and Asia Minor. It is computed that there are nearly 50,000 corpses either above ground or buried just under the surface, and unless prompt and efficient measures be at once taken, the result to the whole of Europe may be easily imagined when the hot weather shall have set in. The insurance companies of Austria appear to have taken the initiative, which, having surveyed the country, now request a European disinfection upon a gigantic scale, as the only means of averting a terrible catastrophe. The idea of huge cremating kilns is favoured by a large section of sanitarians, that of destruction by quicklime by another, and a third maintains that burial in deep ridges will ensure all that is required. We are disposed to suggest the immediate setting in motion of all three processes, there is unfortunately work enough, and if it be not done at once, the world may witness one of those frightful epidemics of cholera and black plague which sends a shudder through one to contemplate.

The Pedestrian Competition.

On Saturday night O'Leary completed the extraordinary task of walking 520 miles in six days—the greatest distance ever accomplished in so short a time.

We have, on a previous occasion so fully entered into the conditions which make these feats of pedestrianism physically possible and comparatively harmless, as well as into the reason why such exhibitions should not be altogether discouraged, that we have little to add to what we have already said on the subject. To put the chief points on which we then laid stress categorically, these great walks undoubtedly show:—1. That, with regard to walking, the human frame is capable of enduring, under certain conditions, much more sustained exertion than most people think it possible. 2. That great powers of endurance, under the most trying conditions, do not, as was shown by Gale's physique, depend so much upon the size of the muscles, the girth of the chest, &c., as upon strength of constitution, potentiality of the nervous force or energy, and an indomitable spirit and force of will that are quite independent of great muscular strength. 3. That for this reason, and from the fact that the act of walking is, in a great measure, automatic and made easy by exercise; there is no one who might not, by a little practice, treble his walking powers, and, thereby greatly benefit his health. 4. That much and continuous walking is not such a tax upon the brain, and does not necessitate so much sleep as would be required in the case of great intellectual exertion or mental strain of any kind, and that, consequently, most of those individuals who make very little use of either their limbs or their brains, are in the habit of taking much more sleep than they require. 5. That short and irregular periods of profound sleep will, under the pressure of circumstances, often fulfil the requirements of the system.

Nevertheless, we admit that these experiments should not be too often repeated, and that harm may be done by giving too much encouragement to practices that may jeopardise the future health of those who indulge in them. As we remarked before, it would be better if a little of that zeal for physical exercise which is now limited to a few distinguished athletes, undergraduates, and public school-boys, was more widely spread among all classes of the community, and adopted as a means of preserving health and warding off disease.

Sentence on a Medical Man.

At the last Antrim Assizes, before Judge Lawson Owen Patrick O'Hare, an A.B., and M.D. Q.U.I., M.R.C.S.E. and L.A.H., was indicted for having forged a writ, by means of which he endeavoured to recover money which he alleged to be due to him.

Counsel said that the prisoner had lost his power of speech, and had been suffering from paralysis for upwards of a month. Counsel put in a plea of guilty, and advanced several circumstances in extenuation. Since his incarceration, he had suffered both mentally and physically.

His Lordship said he had taken into consideration the state of the prisoner's health, and statement of his counsel. The sentence of the Court was 12 months' imprisonment.

Treatment of Sexual Exhaustion.

In the *Medical and Surgical Reporter* there is an account of the treatment of this condition, adopted by Dr. H. C. Wood, jun., but it is given with a precision and an amount of confidence which might lead the reader to suppose that sexual exhaustion, especially when arising from onanism, is more more amenable to treatment than is generally found to be the case. Of course, says Dr. Wood, the habit (of masturbation) must be given up at once; then the hygienic treatment is in order, and this consists in plenty of physical exercise, use of farinaceous food, abstinence from meat as far as possible. Whatever tends to excite and irritate the genitals in the way of exercise, company, literature, &c. should be absolutely forbidden. The object of the medical treatment is to subdue the excessive irritability of the parts, and this may be done by potassium bromide, grs. xx. to grs. xxx. three times a day, or bromated camphor, grs. v. in emulsion at the same intervals. Iron and some bitter tonic may be profitably employed in conjunction. Ergot is frequently of use. In the treatment of excessive venery, continence is again requisite. Where the emissions are numerous, the same hygienic measures as in cases of masturbation must be employed. Nourishing food, warm clothing, and plenty of sunlight and exercise are indispensable. Iron, bitter tonics, and the bromides are indicated. Phosphorus is a specific remedy, and may be given alone or with ergot.

Impotence, due to excessive irritability of the organ, should be treated with continued doses of the bromides.

Where there is loss of power without irritability, the tincture of cantharides and the tincture of iron should be given. In impotence with spermatorrhœa, the tincture of cantharides acts like a specific, but it should not be given where debility is absent. If further treatment be required, cold bathing, strychnia, and electricity may be employed.

Ovariotomy.

Dr. Laffan performed ovariotomy on the 1st of March. The tumour was of the size of the uterus at full time, and was unilocular and unattached. Bichloride of methylene was the anæsthetic employed, and this was administered by means of Gunker's inhaler. During the entire proceedings a continuous shower of thymol spray was maintained through the agency of a Fletcher's apparatus. The patient is now (21st March) convalescent.

The Council of the Royal College of Surgeons of England resolved, on the 14th inst., that the registration of medical students at the College be no longer required on and after this date.

Correspondence.

THE ADMISSION OF WOMEN TO THE BRITISH MEDICAL ASSOCIATION.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—The members of a liberal profession are to meet at Birmingham on the 2nd of April, to consider whether two ladies, who *de jure* and *de facto*, are members of the British Medical Association, should be deprived of their privileges. It seems to me perfectly ridiculous to call a meeting for such an object, and quite unworthy of the leaders of our profession. Will the result of the meeting be an expression of the will of the majority of the members? Hardly, I think, as at this time of the year a large number of the practitioners will be unable to attend, and unless voting is allowed by proxy, or by voting papers, the result of the meeting will be unsatisfactory. London should have been the place of meeting. Why Birmingham has been selected is best known to the wire pullers?

Yours faithfully,

A Member.

THE RECENT WALKING MATCH.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—Having been requested to professionally visit the men during the "Pedestrian Competition," I think it only fair to notice, in an International Medical Journal, the great disadvantages, doubtless unintentional, under which the Englishmen, and others, laboured in that contest. No one could honestly dispute the extraordinary endurance, and the admirable power of will and self-denial which O'Leary displayed, as he worked his machine-like body by day and night, qualities which went far towards giving him the victory. But when I contrast the conveniences and comforts as to food and rest, and the excellent attendance which he enjoyed in his well-appointed tent, with the almost entire absence of any such advantages for his competitors from all parts of the United Kingdom, I am not surprised at the result. For example, Vaughan (2nd) had to fare on lumps of indigestible steak, which made him retch, or a mixture of beer in a tea-cup, and rice-pudding equally unstomachic; while Brown (3rd) was gorged with "speedy-cake;" and in either case their attendants seemed to have only one restorative for the patients as they lay in their wretched hovels, that of rubbing the legs in the wrong direction—downwards, against the course of the circulation. So far as I observed, not one of the competitors—except O'Leary—had a second pair of boots, and the boots worn were too short and narrow-soled. Thus, in one case, matter formed under the great toe-nail, when only 151 miles had been walked; and yet the owner of the suppurating toe was a champion pedestrian, Smythe, of Dublin, having quite recently performed the unprecedented feat of 2,000 miles in 1,000 hours.

Nothing could exceed Sir John Astley's kindness, and even his personal attention to the men; and Mr. Atkinson promptly supplied every requisition. But under the unprepared conditions I have briefly depicted, the competition was not a fair one—on even terms.

I might add that while the victor pursued his course without any balking interruption on his own track, his numerous competitors, on a track only a little wider, were often dodging one another face to face as on a crowded footpath, a kind of collision which was not calculated to maintain their mental equilibrium, and their co-ordinated movements for progression during a six days trial.

I am, yours faithfully,

Frederick J. Gant, F.R.C.S.,
Senior Surgeon to the Royal Free Hospital.

Connaught Square, March 25th, 1878.

INITIATION OF SPONTANEOUS EVOLUTION.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Dear Sir,—Having seen Dr. Tuckey's letter on the above, reminds me of at least one case in point, and which I am sorry I did not report at the time. It was in February, 1864, I was called to visit Mary Cashen, labourer's wife, aged 20, (primiparous), at Windgap, co. Kilkenny, she had been left for some time, with the arm of the child born, and extended to its fullest extent. Owing to the usual consequences of delay, and injudicious meddling by ignorant women, I found it impossible to "turn" in the usual way. I tried steady gentle traction on the arm of the child, and in about twenty minutes, spontaneous evolution, and the birth of the body of the child took place seemingly with one single effort of the uterus; the delivery of the head, and the placenta was effected, without difficulty or delay; the child was dead.

In connection with Dr. Tuckey's idea, that the right ovary is productive of males, and the left of females, it may be amusing to him to hear, if he is not already aware of the fact, that the Irish peasant believes he can secure the birth of a *son*, by causing his wife to sleep on her *right* side after coition. *His* idea, however, is not based on his knowledge of physiology, but on his slight acquaintance with the "Mosaic account of the creation," from which he gathers that the *female*-producing rib was taken from the *left* side of Adam. As Dr. Tuckey modestly says, I give this for what it is worth.

Yours truly,

W. B. Phelan.

Rockferry, Cheshire, 14th March, 1877.

Medico-Parliamentary.

HOUSE OF LORDS. — March 19th.

AMENDMENT OF THE MEDICAL ACTS.

The Duke of Richmond and Gordon, in presenting a bill on the subject of the Medical Acts, said that the bill introduced and passed in 1858 had three objects—first, to raise to a uniform and sufficient standard the degree of education and the acquirements of those allowed to practise; and, secondly, to establish an authoritative register of the names of all persons qualified to practise. It also provided for removing local jurisdictions which prevented any competent man practising out of that part of the country where the various bodies had authority. The preamble of the bill set out that it was expedient that persons requiring medical aid should be able to distinguish qualified from unqualified medical men. That was a preamble in which they must all agree. The bill was drawn with a view to carrying that out, and he was bound to say the measure had to a great extent been successful; but, in the lapse of time since 1858 various things had happened to show that it was desirable to amend the law. By the law of 1858 the mode provided for distinguishing between qualified and unqualified practitioners was first of all by setting up

a medical council. Then it provided that single qualifications from any one licensing body should entitle the practitioner to be placed on the register of qualified persons. There was still a general supervision under the Medical Council, and other important clauses were included in the bill. He believed and hoped that the English bodies had been endeavouring to form a conjoint scheme and a conjoint board, and he also hoped that before his bill was passed English bodies would have come to such an agreement as would make possible the formation of such a board. There was, he knew, a difficulty with regard to Scotland, the universities and corporations there being somewhat different to those in this country. It had not been found desirable, therefore, up to the present time, to include Scotland in the formation of a conjoint body. He trusted this difficulty was not one which was insurmountable, and that there might be provisions in the bill by which Scotland might, if she wished, join in the conjoint scheme. In Russell Gurney's Act, enabling women to be examined, the wording compelled them to be members of the senate of the corporation, which was never really intended. The principal objects of the bill he intended to bring in were—to require persons registered to have better medical and surgical qualifications than at present, to allow the registration of foreign and colonial practitioners, to restrict the assumption by unqualified persons of designations implying qualification, to secure uniformity of qualification, to make provisions for women similar to those intended to be made by Russell Gurney's Act, and to provide for the examination and registration of dentists and midwives. He now came to the mode in which these various objects were to be carried out. The third clause prevented a person being put upon the register unless he had two diplomas, one in medicine and one in surgery, or obtained a certificate in proficiency both in medicine and surgery from the medical board established under the Act. This provision would not apply to persons who were on the register at the time of the passing of the Act, and would not, therefore, have a retrospective effect. The next clause provided that any person who had obtained a medical diploma entitling him to practise in any colony or any foreign country should be registered on proof of good character, if his diploma was one recognised by the Medical Council as a diploma representing a degree of knowledge tested by examination equal to that which was obtained by those who practised in the United Kingdom. If the Medical Council refused to grant a license to a foreign or colonial practitioner, there was an appeal to the Privy Council by a party who felt himself aggrieved. It was also provided that the colonial and foreign practitioners should be entered on a separate register from that kept for the United Kingdom. The 13th clause required that the General Medical Council, on striking any name off the register, should act by means of a committee of five. As this proceeding was somewhat of a judicial character, it was thought that it should be better entrusted to a small committee than to the larger body represented by the Medical Council. The next clause was important. It extended the powers of the Medical Council in regard to examinations for medical diplomas, and allowed them, with the approval of the Privy Council after the passing of this Act, to make rules regulating the examinations of candidates for diplomas. They were required in these rules to provide for the admission of women to examination, subject to two conditions. The first was that no medical authority which was not now bound to examine women should be compelled to do so; and the second, that they should make rules by which women should not be compelled if they objected to pass the same examination as men. These examinations, as prescribed by the Medical Council, were the only means by which persons could enter the profession; but the general system of examination was subject to the control of the Privy Council, who might refuse to sanction any feature which they considered objectionable. The next three clauses were those which give the medical authorities power to combine for the purposes of general examination. A scheme for this purpose was contained in the bill, and the board established by the scheme for conducting the examinations was to certify the names of persons who passed both in medicine and surgery. As it would be possible for women to pass these examinations, it was provided that the obtaining of one of these diplomas should not entitle any person to become a member of any of the existing medical corporations. This was to meet one of the difficulties which had arisen under Mr. Russell Gurney's Act, by which women had been practically excluded from being examined. The bill did not attempt to punish any unregistered person who practised; but it prohibited persons who practised for gain from assuming a medical or surgical designation to which they were not entitled, and imposed a penalty for so doing. The next clause in the bill enabled the Medical Council to provide, by means of a scheme, for the examination, licensing, and registering of dentists. There was a measure before the other House of Parliament which dealt with the subject of dentists. He had had the opportunity of seeing and consulting with many practitioners, and that bill was not altogether satisfactory; but he hoped that this measure would effect the objects which the promoters of the other bill had in view in a better way. It provided that no person should assume the designation of a dentist unless he had been registered. There were clauses in the bill dealing with the important and difficult question of midwives. All that they could do was to indicate the best mode of proceeding in this matter, and to endeavour by degrees to elevate the status and education of midwives. The bill allowed the Medical Council, with the consent of the Privy Council, to provide for the examination, licensing, and registration of midwives. There were clauses in the bill touching the Lunacy Acts, which he had forwarded to the lunacy commissioners for consideration. They appeared to be not quite satisfied with these clauses, and he would be happy to insert any amendments to meet their views. These were briefly the more important provisions of the bill. The subject was not only one of considerable importance, but complicated and complex in its character, and it was one on which they ought not to legislate hastily. He hoped before the second reading of the bill to obtain the opinions of many persons who were interested and were competent to give advice on the matter, and he need not say that he would be ready to consider any suggestions that were made to him.

The bill was then read a first time, and the Duke of RICHMOND and GORDON intimated that the second reading would be taken on Monday, the 15th of April.

HOUSE OF COMMONS. — MARCH 22ND.

THE HYGIENIC STATE OF GIBRALTAR.

Sir M. H. BEACH, in reply to MR. GODDARD, said he had only received notice of his hon. friend's question that morning. He was informed that there had been several cases of fever among the officers quartered at Gibraltar last summer, but the fever was of an intermittent and not of a typhoid character, and was not traced by the medical officer to sanitary defects, but to a climatic origin—a late and prolonged rainfall. The sanitary condition of Gibraltar was not, however, altogether satisfactory, but steps have been taken to improve it, and its further improvement was contemplated.

COMPULSORY VACCINATION IN THE ISLE OF MAN.

Mr. CROSS, in reply to Mr. HICK, said a compulsory Vaccination Act not hitherto in force in the island, had passed the legislature of the Isle of Man, which would probably receive the Royal assent on Tuesday. Under the bill the Lieutenant-Governor would appoint public vaccinators, who must be medical men, but who were not required beyond that to have any special qualifications. The Lieutenant-Governor had, however, stated that he should be guided by the same rules in making the appointments as governed similar appointments in England.

THE MEDICAL REFORM BILL.

At length the Government Bill for the remedy of all the medico-educational diseases of the profession, and for the saving of the sick public from the incompetency of diploma-bought doctors, has seen the light, and we know exactly how much and how little of real earnest effort to amend the abuses of our profession is to be expected from the Ministry. We have the Bill before us, and before expressing any opinion upon its provisions, we shall endeavour to give our readers such an epitome as may enable them to judge for themselves. It aims at achieving seven distinct purposes:—

1. To enforce double qualification as an essential of registration.
2. To admit colonial and foreign practitioners to registration in a separate division of the register.

3. To authorise and cause the Medical Council to frame "examination rules," with the view of ensuring competency of practitioners, and to see that such rules are acted upon uniformly by all medical licensing bodies.

4. To enable licensing bodies to combine in a conjoint examination, subject always to these "examination rules."

5. To amend the "quacks" section of the Medical Act, so as to facilitate prosecution and conviction.

6. To register dentists and provide for a general dental diploma.

7. To register midwives.

Taking these objects *seriatim*, we proceed to discuss the first, *i.e.*, to enforce double qualification as an essential of registration. Section three of the Bill says :—

Registration.

3. The same medical registrar shall not register a person . . . unless either such person holds a double qualification . . . obtained after examination in the United Kingdom, or unless such person is a colonial or foreign practitioner entitled under this Act to be registered without examination . . . A double qualification means a qualification to practise both medicine and surgery and shall be either—

(*a.*) A medical diploma granted by one of the medical authorities to a person who has obtained from a medical board under this Act . . . a certificate that he has shown himself by examination to be qualified to practise both medicine and surgery; or (*b.*) separate medical and surgical qualifications under the present Medical Act.

This is, our readers will agree, a very important enactment, and one thoroughly in accord with the wants of the public. Indeed, the necessity of a double diploma as a test of competency to practise has been universally acknowledged, not only in the public services where a double diploma is a *sine quâ non*, but in private practice, in which few medical men attempt to engage until they have armed themselves with both a physician's and a surgeon's diploma. Nevertheless, the section may meet with serious opposition from universities whose single degrees are supposed to cover all branches of both medicine, surgery, and pharmacy, and from a few colleges whose charters give them special rights in this direction. Should the subject come to be seriously discussed, the voice of both the public and the profession will be unanimous in favour of the section, and it will pass despite the opposition of corporations. The second object of the Bill is "to admit foreign and colonial practitioners to registration in a separate division of the register." This is provided for in sections five and six of the Bill, which are as follows :—

Where a person, who is not a British subject, or who has practised medicine or surgery or a branch of medicine or surgery for more than ten years elsewhere than in the United Kingdom, shows that he obtained some recognised medical diploma or diplomas (as hereinafter defined), granted in a foreign country, and that he is of good character, and either continues to hold such diploma or diplomas, or has not been deprived thereof for any cause which disqualifies him from being registered under this Act, such person shall upon payment of the registration fee be entitled, without examination in the United Kingdom, to be registered as a foreign practitioner in the medical register.

A similar clause admits the holder of a colonial diploma to registration in a separate colonial list.

7. Foreign or colonial recognised medical diplomas for the purposes of this Act, shall be such diplomas as may be recognised for the time being by the General Medical Council as entitling the holder thereof to practise medicine and surgery in such . . . country, and as representing at the time of the grant thereof a degree of knowledge, as tested by examination, equal to or greater than that . . . required to obtain in the United Kingdom such qualification as entitles the holder to be registered.

These provisions of the Bill were expected, and were, indeed, inevitable, after the discussion in the last session of Parliament respecting the Bill introduced into the French Senate, which Bill would have disqualified all English physicians or surgeons practising in France. At that time Mr. Cowper-Temple introduced a Bill to legalise foreign medical degrees in England, and an understanding was arrived at that the Government should deal with the subject if the Bill was withdrawn. At the same period the Canadian profession addressed earnest representations to the General Medical Council on the subject of colonial degrees, and it was—after much debate—resolved by the Council that these degrees should be registered in a separate list. The feeling of the profession—as we understand it—is that they have no desire to exclude from practice in these countries any colonist or foreigner who can show as good evidence of education and competency as would enable them to qualify in the United Kingdom. But they are seriously apprehensive that a registration of foreign degrees—unless most carefully guarded by the Medical Council—would let loose upon the British public the holders of sham German or Yankee diplomas, who had fulfilled only a nominal course of study, and passed an imaginary examination. The Bill now before us places the recognition of foreign and colonial degrees at the uncontrolled discretion of the Medical Council; but it does not indicate the means by which that Council is to sift the pretensions of these bodies before recognition. Nor can we. We cannot expect the Council to see for themselves, by visitation of examination, the nature of the tests applied by these foreign licensing bodies, or to ascertain by observation the reality of the medical study required for such diplomas, and we look with great suspicion upon any proposal to register such degrees in Great Britain upon mere hearsay evidence, or upon the assurances of the licensing bodies themselves.

In the succeeding sections of his Bill, the Duke of Richmond deals with the question which is nearest the heart of the profession, and attempts to provide for the third purpose of his measure—*i.e.*, uniformity in the tests of competency to practise medicine. It is not surprising that medical men should entertain strong opinions on the subject. For twenty years the profession suffered from the discomforts of competition with grossly incompetent persons who were enabled by the corrupt connivance of licensing bodies to practise upon the credulity of the public. At length, after much deferred hope, and many promises of amendment, the Medical Act of 1858 became law, and the General Medical Council was created. Alas! the last state of the profession was worse than the first. Tantalised by the phantom of medical reform, and baffled by the indifference and *insouciance* of a conclave, which was less capable of reform and improvement than the licensing bodies which it was created to reform and improve, the profession has for another twenty years waited for a government strong enough to deal with the vested interests which neglect and greed had created. A ministry has at length been found with

sufficient command of public feeling to venture upon the contest, and the result of its deliberations is before us.

The Duke of Richmond sets himself, in the first instance, to remove all difficulties in the way of licensing bodies which desire to form conjoint examinations. He orders that "where any two or more of the medical authorities have, before the passing of the Act, agreed . . . . upon any such scheme, that scheme is hereby confirmed and shall come into operation at the commencement of this Act." Thus the English scheme is made law, but in respect to an Irish or Scotch scheme, it must be subject to the "Examination Rules" set down by the Medical Council, and open to their approval, and that of the Privy Council.

Section 17, which refers to the position of the licentiate after examination is as follows :—

17. A medical board shall with respect to each of the persons who have passed such examination, and paid the required fees, certify that he has shown by examination that he is qualified under this Act to practise both medicine and surgery. . . .

Every person named in such list shall be deemed to have obtained a qualifying certificate under this Act from such board, and shall be entitled on application to receive from any medical corporation being a party to the scheme, one of the medical diplomas which that corporation have for the time being power to grant, but shall not, except so far as the medical corporation otherwise in their discretion provide, be entitled to any share in the government, management, or proceedings of that corporation, or to any rights or privileges in connection with that corporation.

20. A medical authority may from time to time by a statute or bye-law, constitute a new medical diploma, to be granted to them by persons who have obtained qualifying certificates from a medical board under this Act, and may attach to that diploma such rights and privileges in connection with the said authority as may be from time to time provided by any such statute or bye-law.

The same clause makes provision for the registration of such licentiate by the college which grants him the qualifying certificate, and without his own personal application to the registrar. Having thus provided for voluntary conjoint examination, the bill proceeds to arrange for uniformity of examination under the supervision of the Medical Council. The proviso is as follows :—

(1.) The General Medical Council shall from time to time frame . . . rules for regulating the examination of persons desiring to obtain a double qualification . . . and determining the subjects thereof and the standard for passing and the method of conducting the same, and providing for the superintendence thereof by such Council.

(3.) The examination rules shall determine the conditions of admission of candidates to the examinations, and shall provide for the admission thereto on special terms of persons who have obtained medical diplomas or studied in any British possession or foreign country, or have passed other examinations.

Thus the Council is ordered to make rules, but these rules are not binding on the licensing body, and the bill does not put any obligation upon any licensing body to comply with them saving the confirming of the existing power of the Council to report such body to the Privy Council in case of contumacy.

Fourthly, the bill amends the quacks' section of the Medical Act with the purpose of making the prosecution of unlicensed practitioners more facile. The section seems to be extremely comprehensive, and we give it as fully as possible :—

22. If a person who for gain either practises medicine or surgery, or a branch of medicine or surgery, or is engaged in the cure or treatment of diseases or injuries, and is not for the time being registered in the medical register, takes or uses the designation of any qualification or medical diploma which entitles a person to be so registered, (including any recognised medical diploma granted in a British possession or foreign country), or the designation of licentiate in or professor of medicine and surgery or medicine or surgery or a branch of medicine or surgery, or the designation of physician, surgeon, apothecary, or doctor, or any designation used to distinguish registered practitioners of medicine or surgery or of a branch of medicine or surgery, or any designation implying that he has obtained a qualifying certificate under this Act, or is registered or entitled to be registered in the medical register, or is duly qualified to practise medicine or surgery or a branch of medicine or surgery, he shall for every such offence be liable . . . to a fine not exceeding twenty pounds. If a person who for gain either practises medicine or surgery, or a branch of medicine or surgery, or is engaged in the cure or treatment of diseases or injuries, wilfully takes or uses any of the above-mentioned designations to which he is not entitled, he shall for every such offence be liable on summary conviction to a fine not exceeding twenty pounds.

If a person not . . . registered . . . gives any certificate which, under the Medical Act 1858 is invalid unless signed by a person so registered, he shall be liable . . . to a fine not exceeding twenty pounds.

The fifth purpose of the bill is to register dentists—a subject of which our readers have recently heard much. Section 23 provides that the Medical Council *may* submit to the Privy Council a scheme for licensing of dentists "and the examinations in connection with such scheme" may be conducted by any medical authority *who consents thereto.* A dentist's register is provided, and it is ordered that :—

There shall be entered in the dentist's register, with the licentiates qualified under such scheme, every person . . . registered in the medical register who applies to be entered in the dentist's register and pays the said registration fee, and also every person who . . .

(*a*) holds a license in dentistry or in dental surgery of, or a certificate of fitness to practise as a dentist from any of the medical authorities ; or

(*b*) is *bonâ fide* engaged in the practice of dentistry either separately or in conjunction with the practice of other branches of medicine or surgery ; and claims to be registered before the expiration of twelve months.

There shall be also entered in the dentist's register . . . such colonial and foreign dentists as are authorised by the scheme to be so registered :—

(*a*) The registration of a person in the dentist's register shall entitle that person to practise dentistry, but not any other branch of medicine or surgery, and shall not entitle him to assume any designation which a person not registered in the medical register is forbidden by this Act to assume, except that a person registered in the dentist's register may take and use the designation of dentist or dental practitioner, or any designation implying that he is duly qualified to practise dentistry, so that such designation do not imply that he is duly qualified to practise any other branch of medicine or surgery.

It is also provided that persons misrepresenting themselves as qualified dentists shall be liable to prosecution in the same way as quacks are dealt with.

The bill, as we have said, also contains sections providing for the registration of midwives and the qualification of women-doctors, but as it seems best not to encumber the consideration of the important matters to which we have referred by a discussion of these subjects, we defer their debate to another time.

Such is the reform promised by the Government, and we conclude our analysis of it with a feeling of disappointment. We do not expect Ministers or Parliament to look at these subjects from a professional standpoint, or to frame their proposals specially to meet the desires of the class whose interests are involved ; but looking at the reform of the system of medical education and qualification from a purely public aspect, we experience no relief from the disappointment which our observation of the measure with a medical eye has impressed upon us. The Duke of Richmond had better have refrained altogether from the attempt to reform the profession if he did not feel in him the courage to do that which any medical man could have told him needed urgently to be done. Manifestly he has learned and appreciated the wants of medical qualification ; obviously he was conscious that the avarice of competing corporations had operated disastrously against the public interest, and that the Medical Council —in its twenty years of life—had shown itself constitu-

tionally incapable of any earnest or honest effort to mend matters. Nevertheless, he has displayed a lamentable want of the courage of his convictions, has flinched from the contest with vested interests, has fled for very fear of the opposition of the Scotch and other low class colleges, and has humiliated himself to propose a weak compromise with powers over which he should have shown himself master. The miserable policy behind which the Medical Council has been playing hide and seek for nearly twenty years, the *permissive* authority to that pusillanimous tribunal to *recommend* something to a licensing body which that body will not have the least notion of adopting as long as there is money to be made by adherence to the old system; such is the outcome of all the noble Duke's promises, and the realisation of all the hopes of the profession.

The Bill is to be debated by the Medical Council in another fortnight, and, will, no doubt, meet with their warm approval. It is, indeed, a measure after their own mind, constructed upon the policy of masterly inactivity which animates that conclave, and so will be accepted as a blessed reprieve of the representatives (! !) of the profession, who may have apprehended disestablishment and disendowment. We trust that the voice of the profession will be heard outside the Council, with no uncertain sound, that such a reform as may abolish the competition in diplomas, and thus, provide for the competency of all future practitioners in our art, will be demanded with the whole influence of medical men throughout the country, and, if the minister cannot be found capable of dealing with the existing abuses of medical education, let us, at least, not suffer the chagrin of entering upon another twenty years of hopeless dependence on the Medical Council.

Medical News.

College of Physicians in Ireland.—At the recent examinations the following obtained the licences in Medicine and Midwifery:—

MEDICINE.—Andrew Joseph Burke, Robert William Collis, Joseph Leopold Denison, John Elliott Dimond, James Joseph Edge, Robert William Minchin.

MIDWIFERY.—George Ernest Alford, Andrew Joseph Burke, Robert William Collis, Joseph Leopold Denison, John Elliott Dimond, James Joseph Edge. Thomas Frederick Fogarty, Francis Blaney Grew, James Campbell Hall, Robert William Minchin.

The Cancer Hospital, Brompton.—The Annual General Meeting of the governors of this hospital was held at Brompton, on Friday last, George T. Hertslet, Esq. (hon. treasurer), in the chair. The annual report of the committee was read by the secretary, Mr. H. J. Jupp, from which it appeared that there had been a very sensible diminution in the receipts. The broad principle of free admission adopted, had proved a great boon to those seeking relief who were often in so helpless a condition as to render the exertion required to obtain admission in the usual way extremely dangerous. The committee have it under consideration to greatly increase the accommodation for in-door patients by extending the present building. Votes of thanks were accorded to the Baroness Burdett Coutts, to the Hon. Treasurer, to the Secretary, for the efficient manner in which he had performed his duties, to the Chairman for kindly presiding, and to all who had shown an interest in the welfare of the institution.

The Central London Throat Hospital.—A concert in aid of the Health Resort and Convalescent Fund for strumous and other out-patients in connection with this institution, was given at the Royal Academy of Music on Friday last, under the conductorship of Cavaliere Odvardo Barri. The concert was well and fashionably attended, and it is expected that about £70 will accrue to the charity therefrom. The following distinguished amateurs kindly gave their services: Mrs. Neville Lubbuck, Mrs. R. C. Saunders, Mrs. Chas. Eley, Miss Florence Jones, Miss Brough, Messrs. Peel, Hewitt, W. F. Hayes, S. Heilbut, C. Mason, Irving, de Rougement, G. Raggett, and Captain Hutton.

NOTICES TO CORRESPONDENTS.

MR. J. E. ADAMS, F.R.C.S., will introduce "Some Rare Forms of Iritis" at the meeting of the Hunterian Society this (Wednesday) evening.

PROF. DEWAR, F.R.S., will deliver a lecture on Friday evening at the Royal Institution "On the Chemical Actions of Light and their Electrical Relations."

A FELLOW will find the subject fully considered in our present number.

MR. W. H.—Many thanks.

DR. A. W.—If you refer to our last number you will find a criticism of the work.

MR. FOSTER.—1. Yes. 2. Surgeon-General Gordon is at present in medical charge of the forces in Madras; he is named as the probable successor to the Director-General of the Army Medical Department in this country.

AN ECHO OF REGRET.—A correspondent writes under this *nom de plume* respecting medical advertising, enclosing at the same time an advertisement of cough lozenges which appears in the *Echo* and various other newspapers, with a recommendatory letter from a medical man bristling with diplomas, such as they are. Our correspondent is naturally indignant at this method of intruding oneself before the public, and asks if such a practice can be considered respectable. Our opinion has been so often expressed on this point that we need not here repeat it, suffice it that in the eyes of every member of the profession who values his position as a gentleman and wishes to be considered by others as such, it carries its own condemnation. Further, in the case referred to by our correspondent, the individual is not entitled to dub himself "Dr." The announcements might at least be truthful if they cannot be decent.

DR. P.—We shall probably refer to the subject in our next.

DR. DE F.—Quite inexplicable.

EPIGRAM.

(FROM AN OCCASIONAL CONTRIBUTOR).

WHAT news to-day? "Oh! worse and worse,
Why women have now joined our society;
You know it may affect our purse,
Its 'gainst the rules of all propriety."

Pray check your anger, *quantum suff.*,
You're copying from the ladies' school,
For first you make yourself a "*muff*,"
And next you'll want their "*reticule*" [ridicule]

VACANCIES.

Bournemouth Cottage Hospital.—Resident Medical Officer. Salary, £120. Applications, with testimonials, to the Secretary.

Bristol General Hospital.—Physician's Assistant. Salary, £50, with board and lodging. Election, April 25. Applications to the Secretary.

Cape Colony, Alice Dale Infirmary.—Obstetric Physician. Salary, £500, with house, servants, and horse free. Applications, with copies of degrees, which must be of a University in the United Kingdom, to be addressed on or before May 1st, to the Resident Physician as above.

East London Hospital for Children.—Resident Medical Officer. Salary, £60 per annum, with board, &c. Applications to the Secretary on or before April 11th at the Hospital, Shadwell, E. (See Advt.)

German Hospital, Dalston.—Assistant Surgeon. Honorary. Candidates must be German, or thoroughly conversant with the German language. Applications, with diplomas, to the Hon. Sec., on or before May 1. (See Advt.)

Lancaster Infirmary.—House Surgeon. Salary, £120. Applications to the President on or before April 3rd, accompanied with testimonials of moral character.

Manchester Clinical Hospital.—Assistant Physician and Assistant Surgeon. Both Honorary. Applications to the Secretary, Park Place, Manchester.

Manchester, Owen's College.—Lectureship on Ophthalmology. Applications to Dr. Greenwood, Principal of the College.

Warneford Hospital.—House Surgeon. Salary, £100, with board. Applications, with testimonials, to the Secretary at the Hospital, Leamington.

APPOINTMENTS.

BROSTER, A. E., L.R.C.P.L., M.R.C.S.E., Resident Medical Officer to the National Hospital for the Paralysed and Epileptic.

BROWN, Mr. W. H., House Surgeon to the West London Hospital.

CRESSEY, G. H., M.R.C.S.E., L.R.C.P.L., Medical Resident and Secretary to the Hertford Infirmary.

FAHIE, C. J., L.R.C.P., L.R.C.S.Ed., Medical Officer, &c., for the Lusk Dispensary District of the Balrothery Union, co. Dublin.

GARNER, Dr. J. E., Medical Officer for No. 1 District of the Preston Union.

STACK, R. T., M.D. Dub., M.B., M.Ch., L.R.C.S.Ed. F.R.C.S.I., D.M.D. Harvard, Dental Surgeon to the Adelaide Hospital, Dublin.

Deaths.

CHENHALLS.—On March 4, at St. Just, Cornwall, William Chenhalls, M.R.C.S.E., aged 42.

HALL.—On March 17, at Sheffield, Marriott Hall, M.R.C.S.E., aged 38.

LEWIS.—On March 10, at Paddington Street, Marylebone, Wm. Lewis, M.R.C.S.E., aged 41.

MAHON.—On March 9, at Bushfield Avenue, Dublin, Henry W. Mahon, M.R.C.P.L., aged 69.

MORSE.—On March 16, Edward Morse, M.R.C.S., of Upper Kennington Lane, London, S.E., aged 64.

THE CAUSES AND COURSE OF DISEASES OF THE HEART, WITH SPECIAL REFERENCE TO PREVENTION AND TREATMENT. (a)

A Course of Lectures delivered at the West London Hospital.

By J. MILNER FOTHERGILL, M.D., M.R.C.P.,
Assistant Physician to the Hospital, and to the City of London Hospital for Diseases of the Chest, Victoria Park.

VALVULITIS.

The lecturer commenced by pointing out that the different valves of the heart were rather more than merely competent to close the several ostia, and that a certain amount of mischief might go on in the valvular vela, before they became actually insufficient to fulfil their function. These valves are formed from primitive folds of the endocardium, strengthened by fibrous material spread through them. Strain is the great cause of nutritive changes in the valves of the heart, especially of the aortic valves. In some cases there seems to have been an acute inflammation of them, in his experience, chiefly in girls. [The ulcerative form of valvulitis was briefly dismissed: as the lecture was rather engaged with those forms of disease, for which something could be done in the way of prevention, and of treatment.] In ordinary aortic changes, strain is the main cause of valvulitis. In young men this is usually brought on by violent exertion, and is commonly found among strikers who wield the big hammer in foundries and other iron works, and where the utmost efforts are made during the time the iron is hot on the anvil. It is found where there has been violent exertion continued systematically in other occupations, as bargemen. The changes in the aortic valves in the young proceed more rapidly than is the case in older persons. In the young, the changes usually consist of an inflammatory action in the free edges of the aortic cusps, with some dilatation of the arterial conus, so that regurgitation is the form of disease assumed. In elderly persons, there is a growth of connective tissue at the base of the cusps, spreading up to the free edges, making the valves rigid, and so forming an obstruction to the onward flow of blood at the ventricular systole. Then there was also found a like growth in the arterial conus, which becomes contracted, and so a true stenosis is formed. The great cause of aortic valvulitis in advanced life is gout, or chronic Bright's disease; in both of which maladies there is an accumulation of nitrogenised waste in the blood and obstruction to the blood flow in the arterioles, a high blood pressure in the arteries, and hypertrophy of the left ventricle. This keeps up a state of high blood pressure in the arterial system, and the aortic valves are closed with abnormal force, and thus chronic inflammation of them is set up. Hypertrophy of the left ventricle is almost invariably found before there is disease in the aortic valves. As to the management of the first form, the main thing was to change the occupation, as soon as there was hypertrophy of the left ventricle, and an accentuated aortic second sound, telling of the violent closure of the valves on the aortic recoil. In the gouty form, much might be done by dieting the patient carefully, and by the steady administration of potash, so as to slow the morbid process as far as possible.

The lecturer next proceeded to review the diseases of the mitral valve. He pointed out that strain was a great factor in the production of mitral disease, as well as of aortic valvulitis. The mitral valve has to sustain on each ventricular contraction, an internal pressure equal to the distension of the elastic arteries; whereas the aortic valves sustain only the recoil; and from some cases which had come under his notice recently, he was inclined to believe that mitral disease was not rarely induced by strain, in the conditions of high blood pressure in the gouty, and in those who had chronic renal disease. The mitral valve was often secondarily affected in aortic regurgitation, where it was distended by the aortic recoil as well as the ventricular contractions. The great cause,

(a) Abstract of Lecture I, delivered March 27th, 1878.

however, of mitral valvulitis, is acute endocarditis usually found along with rheumatic fever. Here an inflammatory storm passes over the lining membrane of the mitral flaps, accompanied by a growth of connective tissue corpuscles in the fibrous structure of the valves, extending to the chordæ tendineæ. This growth is set up by the active inflammation, but does not usually cease with it; but goes on and on, because the valves can get no efficient physiological rest in consequence of their function. The result is that the growth goes on until the valve is much injured, the vela being bound down to the musculi papillares, the chordæ tendineæ being contracted, constituting insufficiency of the valve; or the free edges are glued together, forming the valve into a cone projecting into the left ventricle, and constituting mitral stenosis; or in other cases, the two valves are soldered together by this growth of connective tissue corpuscles, forming a diaphragm with a slit in it, known as "the button-hole mitral," where there is both obstruction and regurgitation. The lecturer said it was possible to take up the view that this connective tissue growth was a means by which physiological rest was secured for the injured valves; but a means which led to the most serious after consequences.

He went on to say that the practical use of the study of pathology was the aid it afforded us as to the mode of oncome and progress of disease. The observations as to changes in the mitral valve had not been utilised in practice to anything like the extent they might have been, and the influence they ought to exercise over our treatment of mitral valvulitis was very great. In the first place, the inflamed valves should get all the rest possible during the time of acute inflammation. This had been observed by some writers, and absolute quiet insisted upon; but, odd as it may seem, they have not followed the indications furnished by the study of morbid anatomy, and maintained the principle of absolute rest in bed until the growth of connective tissue corpuscles in the valves had ceased too. Yet it was clear that the proper treatment of mitral valvulitis, after the acute inflammatory stage is over, is still to keep the patient in bed, and to lessen the strain upon these injured valves by keeping the blood pressure in the arteries as low as possible, and thus securing such physiological rest for them as is practically attainable. By such measures the after-growth of connective tissue corpuscles will be lessened, and, as the ultimate mutilation is in direct proportion to the growth of these corpuscles, the permanent deformity limited. Such is the rational treatment of mitral valvulitis rather than the plan hitherto adopted of measuring the utility of each plan of treatment by the number of days which elapse before the patient is discharged from the hospital. The plan of giving the patient tonics, if the pulse is feeble, even digitalis, and in every way helping them to get up and about, and thus throwing more strain upon the mitral valve, is as mischievous as any that could be devised to do the patient permanent injury. In fact, at present, the patient is either left alone or is being directly damaged during the very time that treatment is most essential, and injury may be warded off which can never afterwards be undone. This would be much better than waiting till the mischief is done and then trying to set up or further a new balance by muscular hypertrophy of the right ventricle with its concomitant changes. In established mitral disease digitalis was most useful. Even when permanent and irreparable mischief is done, if the compensating changes in the right heart are good, life may be prolonged for years, even when it is necessary for the patient to labour for a living.

The pulmonary valves are rarely affected in extra-uterine existence, even when much of the stress of the systemic circulation is thrown upon them by mitral insufficiency. The tricuspid valves, however, are often affected secondarily, and when the valves become incompetent the treatment is less effectual because they have no decided muscular chamber behind them to be acted upon. Unloading the venous congestion, especially that of the valveless portal circulation, here is a good palliative measure, along with the administration of digitalis, strychnia, iron, and good food.

FRACTURE OF THE SPINE. (a)

By F. W. WARREN, L.K.Q.C.P., F.R.C.S.I.,
Late Resident Surgeon, Steevens's Hospital, &c.

PERHAPS in the whole range of surgical science there is no subject of greater interest than fracture of the spine and resulting injury to the spinal cord, both from its very great gravity and almost hopeless prognosis; and also from the many curious physiological and pathological speculations which are presented to the mind of the scientific inquirer in dealing with injury inflicted upon the cerebro-spinal axis.

As time would not permit of dwelling at any length upon *all* the points connected with a subject of such magnitude, it is my intention in this paper, to limit my observations to fracture of the vertebræ in the lower part of the cervical region, dwelling more particularly upon the thermic variations observed in such injuries, and which in the latter of the two cases, which I shall now detail to the society, were very striking.

CASE I.—John W—, æt. 32, a dairyman of extremely muscular frame, was admitted into Steevens's Hospital, Sept. 5th, 1874, under the following circumstances: Whilst doing some work upon the top of a large haystack (being at the time under the influence of drink) he missed his footing, and fell headlong to the earth (a distance of 25 feet), the vertex being the first part of his body which came in contact with the ground. He was rendered quite insensible by the fall, and was immediately conveyed to hospital.

On admission, he had recovered consciousness; there was a scalp wound over the vertex, but the bone was uninjured. The sphincter ani was paralysed. allowing of discharge of fæces; there was no incontinence of urine; the patient complained of great pain in cervico-dorsal region, and complete inability to move his lower limbs. Manipulation of the parts in the neighbourhood of the root of the neck posteriorly caused great pain. No irregularity in the line of the spinous processes of the vertebræ in this region could be detected, but such an examination was necessarily rendered somewhat obscure by the great muscularity of the patient. There was complete paralysis of both sensation and motion below a line carried round the body at the level of the nipples. He swallowed without difficulty. The upper limbs were perfectly normal as to sensation and motion. The respiratory movements were performed with great labour, the act of expiration being especially difficult. There was no priapism. Temp. in axilla 99°; pulse 80, weak, and compressible. Towards evening of the day of his admission, priapism became well marked; a catheter was introduced, and a pint of acid urine evacuated. He passed a very restless night, the dyspnœa becoming very distressing, with audible rattle of mucus; the following morning the abdomen had become very tympanitic, a catheter was again introduced, and a little acid urine drawn off. Priapism still was well marked. Temp. 101·4°; pulse 110; respiration 36. The paralytic symptoms remained as before. The patient gradually sunk and died apparently from dyspnœa twenty-four hours from the receipt of the injury. There was no rise in the temperature after death. A *post-mortem* examination was made twenty-four hours after death; the livid discolouration of the posterior aspect of the trunk, so frequently observed in these cases, being very well marked. The bodies of the last cervical and first dorsal vertebræ were comminuted in small fragments with extensive laceration of the intervertebral substance; the articular processes were forcibly separated, and the laminæ and transverse processes fractured. On opening the spinal canal, a large quantity of blood was found extravasated in the neighbourhood of

(a) Paper read before the Surgical Society of Ireland.

the fracture on the surface of the meninges, and a fragment of the first dorsal vertebra had penetrated the theca vertebralis, lacerating and destroying the *medulla spinalis at this point.*

Case II.—John D—, æt. 46, a stone-mason, was admitted to Steevens's Hospital, Sept. 10th, 1874, with the following symptoms :—The patient, though conscious, presented the symptoms of collapse, viz., pallor of the countenance, coldness of the surface and extremities, pulse weak and fluttering, about sixty in the minute. He complained of severe pain at the back of his neck, increased by pressure, or the slightest attempt at movement. There was well marked priapism. There was complete paralysis of motion and sensation below a line carried round the chest about two inches above the nipples, and including both upper extremities. When the integuments over the abdomen were pinched severely, he stated that he perceived it slightly, but in every other region of the body below the point indicated, sensation was totally lost. There was no discharge of fæces. No irregularity of the spinous processes in the cervical region could be detected ; this examination caused great pain. Temp. 97° ; pulse 80 ; resp. 22. There was a contusion of the scalp over vertex. The patient gave the following account of the manner in which the accident occurred :—Whilst engaged taking down a scaffold, one of the poles fell upon him, striking him upon the vertex, and felling him to the ground ; he was rendered unconscious by the blow, and was immediately conveyed to hospital. He was placed upon a flat mattrass, with the head slightly raised, as this position gave relief to the intense pain at the back of the neck, and the urine was drawn off. Slight rotation of the head was the only motion he could accomplish, and this caused great pain in the neck.

On the morning of the second day, the respirations had become very laborious, with accumulation of mucus in the air passages, which the patient was totally unable to expel. Priapism continued, though in a less degree. Slight reflex movements could be excited in the toes by tickling the soles of the feet. The abdomen now became tympanitic, and the face extremely livid. Temp. in axilla 103° F. ; pulse 98. At four o'clock in the afternoon, the temperature had risen to 106° F. and the pulse fallen to seventy-six per minute. Resp. 50; and that night the patient died, thirty-four hours after the receipt of the injury. I examined the temperature two hours after death, when the thermometer registered 105° in the axilla. At the autopsy, the same livid discolouration of the posterior aspect of the trunk, as in the former case, was observed. On removing the cervical portion of the spinal column, a partial luxation forwards of the fourth and fifth cervical vertebræ was discovered. When the spinal canal was opened, a small quantity of extravasated blood was observed upon the theca vertebralis. On slitting up the theca, the cord presented a perfectly healthy appearance, with the exception of a narrow band of discolouration or livid ring (about three inches in depth) opposite the fourth cervical vertebra, and on making a longitudinal section of the cord at this point, an elongated narrow clot of blood, about half an inch in length, and corresponding to the external lividity, was found occupying the centre of the medulla spinalis. The intervertebral substances above and below the fifth cervical were extensively lacerated.

In both of the above cases there was injury of the spinal cord in the cervical region, with paralysis, produced by *indirect* violence applied to the vertex ; although agreeing in these particulars, they present, however, many marked points of contrast ; thus, in the *second* case there was no fracture, but a displacement forwards of the fourth and fifth cervical vertebræ, with laceration of the intervertebral substance ; the lesion was much higher up in the cervical region, which accounted for the paralysis of the upper extremities ; thirdly, the anæsthesia was not so complete ; fourthly, the temperature was much more elevated ; and lastly, reflex movements were excitable in the lower limbs. The slight sensation on abdomen was, I think, explained by the *post-mortem* examination, which revealed that the spinal cord itself had escaped laceration or injury from pressure, and that the loss of function depended upon the extravasation of blood in the substance of the medulla towards its centre, the outer portion remaining intact and regaining its function slightly, as the effects of concussion passed away. As in the above cases, the most common period of death, after fracture of the lower five cervical vertebræ, seems to be from about twenty-four to forty-eight hours from the receipt of the injury ; but there are many well authenticated cases on record, which show that this is by no means invariably the case. Mr. Hilton records a case which survived fourteen years (*Lancet*, Oct. 27, 1860). Mr. Greenwood's case recorded in Sir Astley Cooper, "On Dislocations," p. 472, survived fifteen weeks and six days, the injury being at the fourth and fifth cervical ; and in Dupuytren's celebrated case, the patient survived four months after fracture of the fourth cervical vertebra, caused by a fall on the back of his neck. This patient had paralysis of the bladder and extremities ; he was admitted into the Hotel Dieu, and after two months and a half of entire rest, he was convalescent and quitted the hospital, with only slight weakness in his left leg, and with his head a little bowed forwards. In returning from a long walk, he fell paralysed, and remained in the open air all night ; thirty-four days from this he died. On examination after death, the body of the fourth cervical, and the processes of the fifth were found to be broken, the fourth cervical being displaced forwards, and pressing on the cord. The fracture was united by true callus. The cord itself exhibited an annular constriction, which Dupuytren conceived to be the seat of the original lesion, narrowed by cicatrisation.

In the above cases, which I have detailed to the society, death took place in twenty-four and thirty-four hours respectively. The treatment adopted was purely expectant ; laying the patient upon a perfectly flat mattrass, and evacuating the bladder at regular intervals by means of the catheter. Should the patient survive any time, bed-sores should of course be guarded against by all the usual means, and I may here mention a treatment of bed-sores when they have formed, which I never saw adopted in Dublin, but which is very highly spoken of by the most competent authorities, viz., the method of galvanism first suggested and employed by Crussel, of St. Petersburgh. It is also of the greatest value in the treatment of indolent ulcers, and Hammond, in his work on "Diseases of the Nervous System," says, he has used it in indolent ulcers with almost invariable success ; and for twelve years employed it to a great extent in the treatment of bed-sores, caused by disease of the spinal cord, and it only failed in two cases where deep sinuses had formed. Mr. Spencer Wells also says he has often witnessed large ulcers, covered with granulations within twenty-four hours, and completely filled up, and cicatrisation begin in forty-eight hours by the method of galvanism ; and, finally adds, that in his opinion, it is the best of all methods for treating ulcers of indolent character and bed-sores. It is carried out as follows :—A thin silver plate no thicker than a sheet of paper, is cut to the exact size and shape of the bed-sore ; a zinc plate of about the same size is connected with the silver plate by a fine silver or copper wire, six or eight inches in length ; the silver plate is then placed in immediate contact with the bed-sore, and the zinc plate on some part of the skin above, a piece of chamois skin soaked in vinegar intervening ; this must be kept moist, or there is little or no action of the battery. Within a few hours, the effect is perceptible, and in a day or two the cure is complete in the great majority of cases. In a few instances, a longer time is required. Mr. Hammond says he has frequently seen bed-sores three or four inches in diameter and half an inch deep, heal entirely over in forty-eight hours.

As is usually observed in injuries of the spinal cord in the cervical region, the temperature, especially in the second case, underwent great elevation, reaching 106° F., and much higher temperatures than this have been recorded. Chossat long ago published an account of some

experiments on animals, in which he found that division of portion of the spinal cord produced a remarkable evolution of animal heat, so that the temperature was raised much above the natural standard. Sir B. Brodie did the same with similar results. He records a case in St. George's Hospital, in which there was a forcible separation of the fifth and sixth cervical vertebræ, attended with effusion of blood in the theca vertebralis, and laceration of the lower part of the cervical portion of the spinal cord. Respiration was performed by the diaphragm only, and of course in a very imperfect manner. The patient died at the end of twenty-two hours, and for some time previous to his death he breathed at very long intervals, the pulse being weak, and the countenance livid ; at the last there were not more than five or six inspirations per minute ; nevertheless, when the ball of the thermometer was placed between the scrotum and the thigh, the mercury rose to 111° F. Immediately after death, the temperature was examined in the same manner, and found to be the same. Mr. Churchill records in St. Thomas's Hospital Reports a temperature of 110°F. a quarter of an hour after death, in a case of fracture of the fifth cervical vertebra. But by far the most remarkable case on record, is that by Mr. G. W. Teale, of Scarborough, in which the astonishing temperature of 122° F. was registered, after an injury of the spine sustained in the hunting field. Mr. Teale brought this case before the Clinical Society of London, and it is published in the *Lancet* of March, 1875. During the case, no fewer than seven different thermometers, made by Harvey and Reynolds, were used, of which four had received Kew certificates. The temperature was generally taken in the axilla, one thermometer on each side, and then the instruments were reversed ; usually the readings of the left side were about ½° higher than those on the right ; the pulse at no time exceeded 120, and was usually between 90 and 100. There was no notable increase in the frequency of the respiration. This patient recovered. From this case alone, we must abandon the idea that the temperature *per se* is an element of danger.

As Mr. Jonathan Hutchinson has written a good deal upon this subject, I corresponded with him, and he is of opinion that the rise in temperature is chiefly due to paralysis of the vaso-motor nerves, permitting of arterial dilation and increased blood supply, especially in the skin ; hence, increase in surface temperature, and probably increased oxidation. The removal of the influence of sensory nerves probably permits an alteration in the general state of nutrition in all the paralysed parts. This change is probably attended at first by increased waste ; hence, we have a possible explanation of part of the increase of blood temperature. Other elements to be considered are the "trophic" centres and nerves ; that the latter travel with the sensory nerves seems certain, but whether the two are distinguishable, is perhaps doubtful. Again, we have Virchow's well known doctrine of an inhibitory centre, situated somewhere in the intra-cranial nervous system, whose influence on the tissues, after injury of the spinal cord, is annulled by the severance of the channels by which it was formerly exercised.

Dr. Burdon Sanderson, writing on this subject, says :— "If in man, or in an animal, severance of the cord takes place below the origin of the phrenic nerves, the respiratory movemements, although altered in their character by the paralysis of the muscles of the trunk, continue, and consequently life is preserved. The phenomena which present themselves in these cases, from their extreme interest in connection with the heat economy of the living body, have of late years concentrated upon themselves the attention of pathologists. Those which are of most importance in relation to our present inquiry are the following : Section of the cord at the level of the seventh vertebra, or accidental destruction of the organ in man, produces as its primary effect an enormous diminution of the pressure on the arteries, in consequence of which the circulation diminishes. The influence exercised by this diminution on the temperature of the body varies both in degree and direction, according to the animal observed and the nature of its environment.

"In man, as is well known from the historical case of Brodie, alluded to above, as well as from many others, it often happens that the bodily heat rises above the normal, sometimes above that of fever. In small animals, such as rabbits, the temperature falls rapidly, notwithstanding that they are so well clothed in fur, and that the observation is made in summer weather. In animals of intermediate size, such as dogs, the result varies, according to the outside temperature and the protection which is afforded against surface cooling, either by the natural covering or by artificial clothing. Thus, if the creature is invested in an envelope of non-conducting material, and kept in an ordinary room, the temperature of the blood inevitably rises to a height which often exceeds that of fever. Without clothing, especially if it be of relatively small size, its temperature rapidly sinks until it dies in collapse.

"From these facts it is obvious that the most striking difference between the heat economy of the injured and that of the normal animal consists in this, that in the latter the bodily temperature is independent of external conditions, whereas in the former it is affected even by very slight changes in the environment. We have already seen to what an almost incredible extent this is true of man. Similarly, it is found that a healthy dog accustomed to the temperature of summer may be exposed to that of a winter's day without the slightest variation. After the cord is divided the same animal must be clothed, even when in a warm room, else it cools too much ; while if the room is only a very little too warm it passes into a state of intense pyrexia. To prevent either result, depression on the one hand, or collapse on the other, the surface loss has to be accurately adjusted to the thermogenesis by artificial means, for the animal has lost its powers of making any adjustment for itself."

Both Dr. Sanderson and Dr. Murri think that "there is no direct physiological relation between the nervous system and the chemical processes on which the production of heat depends, for it has been shown experimentally by Dr. Murri that after the severance of the cord the temperature rises, even when the thermogenitic function may undergo a very great diminution. As, therefore, there is no increase of production, the hypothesis of increased discharge, which is necessarily associated with that of increased production, falls to the ground of itself. Dr. Murri has, however, by another series of researches, furnished us with the direct proof that no such increased liberation of heat takes place. It is a fundamental and well-known fact, that in relation to the distribution of temperature in the animal body, that the greater the vigour of the circulation the less is the difference of temperature between the central and superficial parts, so that by measuring simultaneously the temperature of the skin and that of the rectum we are enabled to judge very accurately of the velocity of the blood-stream. Why this is so is easy to understand. When the arteries are distended and the blood-current is rapid, a larger quantity of blood is brought to the surface from the warmer central parts of the body than in the contrary case. The mass of blood being therefore greater, the cooling it sustains by exposure to the cooler environment of the body is proportionately less, so that it returns by the veins towards the centre at a temperature which does not differ from that which it possessed in its outward course. Consequently, if we find the temperature of the surface much less than that of the central parts we are quite certain that the circulation through the surface vessels is feeble, and that little heat is given off. We are thus thrown back (says Dr. Sanderson) on the one fact of which the importance has already been indicated as affording the most striking characteristic of the thermal state of an animal after section of the cord, namely, that the bodily temperature yields with abnormal facility to the influence of outside conditions, that the temperature equilibrium, to use Vaunyn's expression, becomes labile."

That the variation of temperature attendant on section of,

or injury to, or disease of the spinal cord and other parts of the nervous system, may be partly explained by the help of a vaso-motor mechanism is undoubtedly true, but many of the facts recorded point to a direct influence of the nervous system on the production of heat. When, after division of the sciatic or the sympathetic nerve, the temperature of the corresponding vascular area rises, this can easily be explained on the ground that a larger quantity of warm blood than usual passes through the part.

But I think it is difficult to account by any working of a vaso-motor mechanism for the marked rise of temperature often seen in slight cases of spinal disease, as in Teale's case. It seems hardly possible in such instances as I have mentioned not to entertain the idea of some direct action of the nervous system on heat producing metabolism. I think the great mass of evidence collected from all sources points to the truth of the conclusions arrived at by Mr. Corley in an able paper on this subject, read before this Society in 1874, viz., that there is a heat-regulating region of the cord extending from the third cervical to the upper dorsal vertebræ. 2. That this function resides in the grey matter. 3. That the effects of injury differ ; a simple lesion giving negative results, whilst a continual irritation produces thermal symptoms.

THE INFLUENCE OF GREEN TEA IN COUNTERACTING POISONING BY OPIUM. (a)

By JAMES SEWELL, M.D.,
Professor in the University, Quebec, Canada.

A LADY. æt. 35, had been, for several years, a sufferer from angina pectoris, for which she had consulted a number of medical men, both in America and Europe, and had taken almost every remedy recommended for this painful affection. Of course, amongst these, opium, but there is no reason, whatsoever, to believe that she had acquired the habitual use of this drug in any form.

One afternoon, having been attacked by a more than usually severe paroxysm, she took from a bottle at hand, of her own accord, as much as two drachms of Battley's fluid, and repeated this dose every half hour until she became insensible.

Dr. Sewell was called in to see her at half-past eleven p.m., and is of opinion that she must have taken at least three fluid ounces and a half of Battley's sedative solution of opium. Her condition was then as follows :—

She had had a severe convulsion, and was now cold up to the hips and shoulders, with the face cold and drawn, and the pupils contracted to pins' points. The pulse was not perceptible at either wrist, and the respirations occurred only three times in two minutes. Dr. Sewell regarded her as dying, and another medical man, one of Dr. Sewell's colleagues in the University, considered that life must be extinct within ten minutes.

Having had considerable experience of the efficacy of green tea as an antidote in other poisonous conditions of the blood, Dr. Sewell determined to try it in this case, and making a very strong infusion he threw half-a-pint up the rectum, and retained it there.

In twenty-five minutes there was the slightest possible tinge of red on the lips, and the respirations had increased to six times in the minute, instead of thrice in two minutes.

In fifteen minutes from this time, Dr. Sewell threw up another half pint of the infusion, and steadily noted progress. By four o'clock, a.m., the patient had become sensible, and recognised Dr. Sewell by his voice, but could not see, as she requested that the gas might be lighted, although the sun was shining brightly at the time, and fully so into the room.

By 8 a.m. she was out of danger.

So confident is Dr. Sewell of the efficacy of green tea as an antidote to poisoning by opium, that he says that he would have no fear for one of his children, or feel anxiety at seeing it swallow a wineglassful of laudanum, if he had only an infusion of green tea at hand.

Dr. Sewell's object in making this communication to the Surgical Society of Ireland, is the hope that the remedy may receive a trial in Dublin, and that its adoption here may prove as efficacious in saving life as it has been in Quebec.

(a) Read before the Surgical Society of Ireland, for the Author Jolliffe Tufnell, F.R.C.S.I. (hon. sec.).

EPITHELIOMA OF THE LOWER LIP. (a)

By B. WILLS RICHARDSON, F.R.C.S.I.,
Surgeon to the Adelaide Hospital.

AT the meeting of the Society held on the evening of the 8th of December, 1876, I exhibited sections of an epithelioma I removed, by operation, from the lower lip of a gentleman, then in a pay-ward in the Adelaide Hospital.

The sections, a characteristic specimen of which I have brought here this evening, show the ulcerating stage of epithelioma, with highly developed club-shaped and conical papillomatous looking upgrowths, springing from the ulcerated surface. This section will allow of the members comparing the papillomatous condition of that epithelioma with a less advanced non-ulcerated epithelioma I recently removed, by operation also, from a patient in the Adelaide Hospital. It will not be necessary to give more than a few of the leading points of the case.

The patient, John Barry by name, and about 40 years of age, fourteen months ago, commenced to suffer from a scaling irritable spot, as he called it, to the right of the centre of the lower lip. In course of time a small lump became perceptible, which, increasing in size, so alarmed him that he sought admission to hospital. He was an inveterate smoker but rarely held the pipe with the portion of lip engaged.

There was no family history of cancer. But little dependence, however, can be placed upon the information given to us by patients concerning the family history of their diseases when they venture as far back as their grand-parents, and I suspect no dependence at all upon what they state regarding the diseases of their great grand-parents. Sir James Paget has not overlooked this matter in his clinical lectures, published in 1875.

I had better now return to the case.

When Barry was admitted to hospital a nodule was found in the part of the lower lip he mentioned, a little to the right of its centre. It was nearly round in shape, extremely hard, about the size of a large marrow pea ; and, its upper surface, slightly depressed, monopolised to a corresponding extent, the place of the labial red surface. This part was formed of dense exfoliating horny-looking epithelium. No enlarged glands could be detected. I removed the nodule with small adjoining portions of the lip by a slightly modified V-incision. It is needless to go further into the steps of the operation; suffice it to mention that the wound was healed in six days, and the man returned home on the seventh.

The evening of the day of the operation I made sections of the epithelioma with the freezing microtome. They are very thin, and some of these stained with carmine, I have here this evening. But, were it not that they show epithelioma of the lip in a stage less advanced than it is usually met with, in hospital practice at all events, I should not have felt warranted in occupying the time of the Society with their exhibition. They are, for this reason, however, worthy of comparison with the section having the papillomatous projections to which I have alluded. The following appearances with a little care, can be made out in the sections of Barry's epithelioma :—

1. Great relative development of epithelium which is

(a) A paper read before the Surgical Society of Ireland.

exfoliating at the surface, and at its deepest part dislocating and invading the underlying structures.

2. Pearly globes, some of which are situated in the exfoliating epithelium.

3. Elongated papillæ of great relative length, buried in the living epithelium, and which probably would have formed papillomatous projections had the disease been allowed to run its course. Some of the papillæ span the whole field of Smith and Beck's large angular apertured 1-5th objective.

4. Enlarged sebaceous follicles, but of this I am somewhat doubtful.

I have on the table a section of the healthy lip that the members may compare it also with the epitheliomatous sections.

Clinical Records.

WEST LONDON HOSPITAL.

A Case of Impassable Urethral Stricture Illustrating the Value of Whalebone Bougies in the Treatment.

Under the care of Mr. TEEVAN.

THOMAS F., a labourer, æt. 50, was admitted into the hospital on February 11, 1878.

Previous History.—Twenty-seven years ago the patient caught a gonorrhœa, which was treated by medicine only; had a gleet on him for some time afterwards. Eighteen years ago he put himself under the care of Mr. Worle, of the City Road, who, by gradual dilatation, enlarged his stricture to No. 13, English. He was put into a very comfortable condition, and attended once a week to have an instrument passed. He then neglected himself, and on several occasions had to apply to St. Bartholomew's Hospital and Charing Cross Hospital for relief. Has been gradually getting worse for the past five years, and for the last two the urine has dribbled away "guttatim."

Condition on admission.—Is in fair health. Can only pass a few drops of water after much straining; urine dribbles away night and day. Stricture sub-pubic, situated five inches from meatus externus. No instrument, soft or metal, could be passed through the stricture.

Treatment.—The patient was put to bed and gently purged. Attempts were made every other day to introduce instruments, without success. On Feb. 18 Mr. Teevan managed to pass the smallest olivary metal catheter into the bladder and to draw off some urine. Considerable irritation followed the introduction of the instrument, although not a drop of blood escaped. A few days later, when Mr. Teevan tried to pass the same catheter he could not do so. On Feb. 28, Mr. Teevan, at 3 p.m., managed to introduce one of the finest olivary whalebone bougies, and tied it in. No discomfort was occasioned by its presence, and it was removed on March 2, at 3.30 p.m., when Mr. Teevan successively passed Nos. 12, 13, 15 olivary bougies (Charrière's guage). The man was so well that he left the hospital the same day, with orders to attend as an outpatient, to complete his treatment and learn how to pass a catheter for himself.

Remarks by Mr. Teevan.—In the first place it may be observed that the patient had never used an injection. Amongst a portion of the public there is a belief that strictures are caused by the use of injections, but it is quite fallacious, for I found that out of 412 cases of which I had taken notes, only about one-half the patients had ever used an injection, thus clearly proving the error of the belief. Happily the abortive treatment of gonorrhœa had fallen into disease, and strong injections were rarely used.

It occasionally happened that a metal catheter could not be introduced on the second attempt, owing, doubtless, to some inflammatory swelling and spasm. A metal catheter was a bad instrument wherewith to carry out the treatment by continuous dilatation, for it usually set up so much irritation that its presence could not be tolerated, and there was always the risk that the posterior wall of the bladder, which rested on the tip of the catheter, might slough and be finally perforated. Now, an olivary whalebone was very pliant, and each hour more and more tended to accomodate itself to the shape of the canal, and its olive tip prevented any injury happening to the soft parts. Catgut bougies might advantageously be laid aside for ever, for they had sharp points, which did harm, and, after a few minutes presence in the urethra the bougies became soddened, and finally unravelled into their component strands.

For the relief of retention of urine, filiform and whalebone bougies were invaluable, and, as they were much finer than any catheter, they could be introduced through strictures impassable to catheters. There was an idea in the profession that, in order to relieve retention, it was necessary to pass a catheter, but it was a delusion. If a fine bougie were introduced and allowed to remain in for a few minutes, the urine would flow on its withdrawal, and the knowledge of this fact would often save a patient from an operation. A few weeks ago I was aroused in the night to relieve an officer suffering from retention. I could not introduce any catheter, soft or metal, but managed to wriggle in a fine olivary whalebone bougie, and so relieve the retention. The ultimate cause of retention in tight strictures was often the impaction of a plug of thick mucus, and its removal was sufficient for the relief of the retention. When a bougie was tied in the bladder the patient would often inquire how he was to urinate. He could be told he need have no trouble about it, andthat the water would come by the sides of the instrument.

ASYLUM OF EVREUX.

LESION OF THE BRAIN IN AN EPILEPTIC—ABSENCE OF THE INFERIOR PARIETAL LOBULE OF THE RIGHT SIDE WITHOUT OCULAR DERANGEMENT ON THE OPPOSITE SIDE.

Under the care of Dr. CLOVIS GALLAPAIN.

Imbecility - Epilepsy—No Visual Derangement — During the last Six Months Cephalalgia—Vomiting—Somnolence—Apoplectiform Attac s - Hemiplegia of Right Side—Encephaloid Cancer of the Left Frontal Lobe, with an Extension into the Lat ral and Third Ventricles—Absence of Development of the Gyrus Curvis (*Pli Courbe*) *and of the Lobule of the* Gyrus Curvis *on the Right Side.*

Guillem, Julie-Louise, æt. 39, was admitted to the Asylum at Evreux, on the 18th May, 1875. She had been a patient at the Salpêtrière, which she entered on Nov. 6, 1851. Discharged from this hospital on the 4th July, 1860, she was admitted a second time on the 29th June, 1861, and remained there up to the period of her transfer to the asylum at Evreux. The certificate of Dr. Moreau, declared that she was suffering from epilepsy.

Guillem is an imbecile, who does not know her own age, and who has no power of "initiation." She requires surveillance and direction in all her actions, but she is quiet and is easily managed. During two years, attacks only of the *petit mal* were observed, consisting of vertigo, accompanied by some twitching of the muscles, and more frequently by convulsions of the muscles of the face: these attacks were never followed by agitation, she had a slight embarrassment of speech, and dragged, slightly, the left leg; no visual disturbance.

May 4, 1877.—Had to-day three violent attacks, not preceded by a cry, which consisted in falling, loss of consciousness, clonic convulsions, a state of coma; her tongue has been bitten deeply.

5th.—Two attacks.

9th.—Three seizures, similar to those of the 4th, not followed by agitation, but by very deep stupor. Since these attacks she continually complains of cephalalgia, more or less violent, affecting particularly the left side.

July 14th.—Obstinate cephalalgia developed, especially pronounced on the left—continued somnolence, which confines her to bed; nausea, sometimes vomiting. This state has lasted more than a month. She is often discovered striking the left side of her head with her hand.

August 7th.—Same state; constipation; prescribed *eau de seidlitz*, purgative clysters, and ptisan of barley.

15th.—Feels a little better, suffers from her head; somnolent.

23rd.—Had to-day ten or a dozen apoplectiform attacks, preceded or accompanied by vomiting, and consisting principally in loss of consciousness, muscular resolution, immobility, with swollen features, &c. (*face vultueuse*).

24th.—Paralysis of the right side noticed; deviation of the mouth and features to the left, drooping of the right upper eyelid; sensibility increased on the right; pulse strong, full; perspiration general; somnolence.

25th, 26th.—Same state; cannot take any food.

27th.—Comatose.

28th.—Comatose state still continues; pulse very strong full, *face vultueuse;* 200 grammes of blood taken away; a clyster, croton oil one drop, sulphate of soda 15 grms.

29th.—Better. The state of coma almost disappeared. Powder of digitalis, 0·10 centigrammes.

30th.—Improvement. Powder continued.

Sept. 4th.—Can raise herself, and use the paralysed limbs.

15th.—Can use fairly her right arm, but cannot walk without assistance; always complains of cephalalgia, and often strikes the left side of her head, continued tendency to sleep.

27th.—Somnolence; cephalalgia; nausea and vomiting; several slight apoplectiform seizures.

29th.—Comatose; leeches to the anus.

Oct. 2nd.—Improvement; clyster of aloes and savon, 5 grains.

9th.—Can raise herself, but has become *gateuse;* always complains of cephalalgia.

14th.—Vomiting; and apoplectiform attack; somnolence.

15th.—Vomiting; coma becoming more and more pronounced. Death in the evening.

AUTOPSY.

Cranium.—The right parietal presented towards the middle an elevation more marked than in the normal state, corresponding to a deep ovoid hollow, on the internal face this cavity measured antero-posteriorly 6 centimetres and a half, and transversely 4½ centimetres. The bone at this point is very thin.

Meninges.—On incising the dura mater, about 200 grms. of serosity flowed from the arachnoid cavity, the pia mater is vascular, but thin. Numerous corpuscles of Pacchioni are implanted on the portion of this membrane covering the feet of the second and third right frontal convolutions; they also exist at the top of the frontal lobe; the dura mater is thin and sieved. The pia mater at the top of the right inferior lobule is thickened and opaline, and raised, presenting the same dimensions as the *fosse* before mentioned; it formed a fluctuating tumour, from which escaped, on incision, a quantity of serous fluid.

BRAIN: *Right Hemisphere.*—Weight, 311 gr.

The first frontal convolution is very voluminous, and occupied almost half of the external face of the frontal lobe. The *insula* has a smooth aspect, and did not present on its surface any appearance of a convolution. The ascending frontal convolution is divided in the middle, into two trunks by a *sillon*—the inferior piece is again cut into two, by a second sillon.

In place of the inferior parietal lobule a deep ovular excavation is found, extending from the fissure of Sylvius in front, to the parieto-occipital fissure behind.

This excavation is six centimetres in length, two centimetres and a half wide, and nearly two centimetres deep, its bottom is a plane surface, corresponding in its anterior third to the external face of the *corpora striata.* Behind, the excavation is separated from the lateral ventricle, by a membrane from 1 to 2 mm. in thickness. The ascending parietal convolution only exists for a length of two centimetres and a half. In a word, this excavation resulted from the absence of development of the inferior thirds of the ascending parietal, of the superior extremity of the first temporal convolution, and especially of the "pli courbe" and its lobule, of which there is not even a trace. The superior parietal lobule is normal. The superior parieto-occipital fissure is very developed, as well as the paracentral lobule.

Left Hemisphere.—Weight 531 gr.

The pia mater is so adherent to the subjacent tissue, for the greatest part of the external face of the frontal lobe, that it was impossible to detach it. This surface embraces the second frontal convolution, and part of the inferior bifurcation of the first, the latter being atrophied.

The third frontal convolution is normal; the insula is very voluminous and composed of fine convolutions, forming a very prominent lobule, elongated antero-posteriorly and presenting a crest rising above the lips of the fissure of Sylvius. The ascending parietal convolution is thinned at its superior extremity. The para-central lobule is less developed than the right. A soft pulpy mass (reddish white) filled the lateral ventricle, and this substance passing by the foramen of *Monro* occupies the third ventricle. After opening the lateral ventricle, we noticed that the tumour had made its way into this cavity, by the vault of the ventricle, and we find a regularly rounded pedicle, about five centimetres in diameter. Between the tumour and the caudal nucleus are many small clots.

An incision into the middle of the tumour reveals to us that the centre is formed of yellow resisting tissue infiltrated with calcareous granulations, whilst a second incision on the smooth plate noticed on the anterior and superior part of the frontal lobe, shows a nucleus the size of a chestnut, formed of a white resisting milky tissue, also infiltrated with calcareous granulations. The cortical substance (very much altered) of the frontal convolution, and the pia mater, which is intimately adherent to it, form a thin shell, covering a pulpy tissue mixed with blood clots. The white and grey substance of the frontal convolutions are completely destroyed or altered.

The cerebellum and bulb, 150 gr., did not present anything particular, the floor of the fourth ventricle was abnormally vascular.

The heart natural, cavities filled with blood clots. Some tubercles in right lung, other viscera healthy

CLINICAL SOCIETY OF LONDON.

FRIDAY, MARCH 22ND, 1878.

CASES OF EFFUSION INTO THE PLEURAL CAVITY.

Dr. W. H. BROADBENT read notes of three such cases.

CASE 1. *Rapid Effusion of Bloody Fluid into the Right Pleural Cavity at the age of 76; Paracentesis; Recovery.* A gentleman æt. 76, under the care of Mr. Meehan and Dr. Broadbent, unusually vigorous for his years, who had for a few days suffered from dyspnœa after exertion, was found on May 16th, 1877, to have fluid in the right side of the chest up to the level of the nipple; the heart and other lung being sound. Next day the pleural cavity was nearly full, and on the following day quite full. The patient could not now turn in bed without serious shortness of breath. Under these circumstances, paracentesis was considered to be urgently required; and after consultation with Sir William Jenner, was performed on May 19th. Eighty ounces of fluid were withdrawn. The fluid had almost the colour of blood, and rapidly deposited a layer of blood corpuscles nearly an inch thick. Notwithstanding this, the patient made a good recovery, and still remained well. The points worthy of remark in this case were considered to be—2. The rapid

effusion of the fluid, which was unexampled in the experience of the reporter. 3. The large amount of blood which, with the rapidity of the effusion, was suggestive of malignancy. This, however, might be considered as set aside by the recovery and present good health of the patient. Probably the cause was undue exertion. 1. The age of the patient. Advanced age was taken by Dr. Broadbent as a reason for early operation when the pleural cavity was full of fluid. The patient was then less able to bear a long illness, and the want of elasticity of the structures rendered the pressure effects more dangerous, and prevented the falling in of surrounding parts during resorption, should the lung fail to expand.—CASE 2. A second illustration of recovery after paracentesis thoracis in advanced life, was a case of pleurisy with effusion, at the age of 73. The patient, a billiard maker, was admitted into St. Mary's Hospital on September 24th, 1874, with all the signs of effusion into the left pleural cavity, filling it completely, and displacing the heart. On October 6th, five pints of clear fluid were drawn off; and on the 17th, he left the hospital convalescent. He resumed his occupation, and was well twelve months later, but died in 1876.—CASE 3. *Pleurisy of the Right Side, with Effusion; Sudden Death.*—A gentleman, æt. 24, of a phthisical family, but personally healthy, began to suffer pain in the left side in August, 1877; a fortnight later he was compelled, by shortness of breath, to give up cricket and violent exercise generally, but he continued to go out up to September 24th, when Mr. Wigmore was called in; and finding signs of fluid in the left pleural cavity, confined him to his room. On September 28th, the patient was seen by Mr. Wigmore and Dr. Broadbent in consultation, and it was agreed that paracentesis should be performed next day at 4 p.m. There had been no dyspnœa nor other urgent symptom. At 6 a.m., on waking up after a good night, he was suddenly seized with shortness of breath; and after a struggle of two or three hours, died. A *post mortem* examination could not be obtained; but probably the cause of death was thrombosis in the veins of the compressed lung extending to the heart.

THE APPLICATION OF MAGNETS FOR THE REMOVAL OR DISPLACEMENT OF IRON OR STEEL CHIPS FROM WITHIN THE EYE.

Mr. MACDONALD MCHARDY read notes of a case illustrative of such use of magnets. The patient, a man, æt. 31, came under treatment at the Royal South London Ophthalmic Hospital during July last, for an injury to his left eye, caused by a chip flying from either a steel tool, or the hammer with which he was striking the tool. Twenty-four hours after the accident there was commencing slight iritis; an altered reflex from a portion of the cornea indicated where the steel chip had impinged. Before dilatation of the pupil, no lenticular opacity could be detected, and the ophthalmoscope revealed nothing abnormal in the vitreous. Tension was normal. There was but insignificant tenderness. The eye was far easier than on the night after the accident. Atropine drops, two grains to the ounce, were prescribed. The next day, forty-eight hours after receipt of the injury, the eye was quieter. The pupil was widely dilated. Vision equalled six-twelfths. The corneal surface was almost normal, but there was a fragment of metal upon the anterior surface of the lens, occupying a situation downwards and inwards from its centre, and so placed as to be completely concealed, except when the pupil was widely dilated. The lens was seen to be perfectly transparent, except at the small area hidden by the chip, which was a long narrow strip. From the position and shape of the chip, Mr. McHardy judged that if left alone, it was certain sooner or later to gravitate down behind the iris, and lead to destructive mischief of one or both eyes; hence, that its removal was imperative. Recognising the possibility of the lens capsule being wounded by the chip, notwithstanding the continued transparency of the lens, possibly through the chip by its very presence plugging a laceration in the lens capsule, and thus excluding the aqueous; he could not feel sure that the lens capsule was then so damaged as to necessitate the formation of cataract. He hesitated to subject the eye to the dangers attending the extraction of a transparent lens by the scoop, and was not satisfied that such a measure would insure the removal of the chip. The use of forceps for removal or di lodgment of the chip was undesirable, as they would almost certainly wound the lens capsule, and through occasioning a loss of the aqueous, would cancel the hydriatic action of the atropine, so as to conceal the chip from view. To meet the requirements of the case, Mr. M'Hardy devised a magnetic spatula, which, being inserted through a needle-puncture which it just plugged, would prevent an escape of aqueous, and the attendant diminution of the pupil, so allowing the foreign body to be manipulated whilst fully in view. Mr. McHardy had preferred a spatula which was an electro-magnet, as he could apply such an one to the chip before calling the attractive force into play; and this power could be interrupted at pleasure, so that any undesirable position of the fragment, with reference to the spatula, might be changed, thus obviating the risk of damage to the lens capsule which would be incurred if the chip were induced to jump across, on the approach of a permanent magnet. Seventy-two hours after the accident, when the condition of the eye was that described on the previous day, his colleague, Mr. Brundell Carter, suggested that before introducing the spatula, it should be tried what, if any, influence a magnet would exert through the cornea upon the chip. Accordingly, Mr. McHardy sat the man up in a chair, held before his eye a powerful electro-bar magnet, with the result that when its pole was four inches from the cornea, the chip was seen to spring away from the lens to the inner surface of the cornea. On withdrawal of the magnet, the chip fell into the anterior chamber, whence it was evacuated through an ordinary iridectomy incision. As soon as the chip left the lens, it revealed a patch of opacity precisely of its own size; it was, therefore, evident that complete cataract might be anticipated. This followed, and the injured lens underwent absorption without setting up any inflammatory reaction. Atropine was continued during the absorption, and the patient, who was present, had normal distant vision with a lens of twelve dioptrics, and read No. 1 of Jaeger's types with a lens of fifteen dioptrics:—the most favourable possible issue to such a case, and one that had been attained without subjecting the eye to any danger other than that directly produced by the entrance of the chip. Mr. McHardy was indebted to Mr. Ladd for the loan of the large magnet, as well as for valuable hints respecting the battery power to be used; and to Mr. Faveaux, of the firm of Messrs. Weiss, for the great prompt and faithful pains he had taken in carrying out the suggestions for making the electro-magnetic spatula which was exhibited. In his concluding remarks, Mr. McHardy quoted from a paper by Dr. McKeown, in the *Dublin Journal of Medical Science*, who had successfully used magnets for the removal and diagnosis of chips of steel or iron in the vitreous. He said that this case had so enlisted his interest in the subject, that he looked forward to carrying out investigations with a view to ascertain the most favourable conditions under which the magnetic power could be applied for these purposes.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

AT the meeting of the Society held 26th ult., Dr. GEORGE THIN read a paper

ON THE CONDITION OF THE SKIN IN TINEA TONSURANS,

in which he described the appearances seen in section through the entire thickness of the skin of a horse affected with ringworm. The spores of the tricophyton tonsurans are found amongst the most superficial scales of the horny layer of the epidermis. They are found in the cutis only in the shaft of the hair, and between the shaft and the internal root-sheath, hair-root, or hair-papilla, or connective tissue surrounding the hair-follicles, in no living tissue in fact. The changes observed in the cutis and rete mucosum, are of an inflammatory nature. The spaces between the bundles of connective tissue are more or less infiltrated with colourless blood-corpuscles (pus-cells), the walls and immediate neighbourhood of the blood-vessels being thickly studded with them. Retrogressive changes are found in the nuclei of the cells of the rete mucosum, and at some parts the epidermis has completely broken down, leaving the cutis denuded. In the latter case the surface is found covered with pus-cells. Small localised abscesses are found in the internal root-sheath and in the rete mucosum. The author suggested that these changes are due to irritation, produced by the absorption of soluble matter set free during the growth of the fungus. The parasite feeds upon effete epidermic structures, and can only assimilate by decomposing them. The incapacity on the part of the fungus to exist in living animal tissues explains the *modus operandi* of the very numerous methods of curing ringworm. Many of the substances applied are simple irritants, whilst the paraiticides in common use are also irri-

tants. Inflammation, when sufficiently acute, cures ringworm, as is shown by the fact adduced by the author, in which a simple wound through a ringworm spot cured the whole patch. It is thus that the beneficial effect in chronic case of a continued slight congestion is explained.

Dr. F. TAYLOR said he was engaged in a similar examination of a portion of the scalp of a child affected with ringworm, and so far as he had gone his results agreed with those of Dr. Thin.—The PRESIDENT said that according to his experience, ringworm was more prevalent among the children of the better classes than among the poor, and Dr. Thin said it was certainly more common in London than in many other places.—Dr. THIN added that the best method to prepare the skin for microscopical purposes was to harden it in alcohol, and after making thin sections, to place them in water, and then in caustic potash.

Another paper was read by Dr. LAIDLAW PURVES, on the

RESULTS OF 100 CASES OF PARACENTESIS OF THE TYMPANIC MEMBRANE.

Of the different methods employed—the knife, the trephine, acids, oils, and ointments, pancreatine, and the galvano-cautery—the galvano-cautery, combined with pressure and ointments, is preferred for maintaining or attempting to maintain a permanent opening, but the maintenance of such is exceptional. The frequent repetition of the paracentesis causes a permanent thinning at the spot perforated, which acts to a certain extent in the same way as a perforation. Of eighty-three individuals operated on, forty-six were benefited temporarily or permanently. In cases of tinnitus one-fourth were benefited. In acoustic affection no improvement occurred. Of thirty-nine cases of cataractous drums twenty-three were improved; five out of seven relaxed drums improved. Of twenty-one paracenteses for the removal of substances from the cavity fifteen were benefited.—Mr. DALBY said that, excluding Astley Cooper's practice, the first in this country to advocate operations on the tympanic membrane was the late Mr. Hinton, in 1868; and he had seen him perform the operation two or three hundred times. But his opinion had changed since then. In many cases in which the operation is performed, there is no fluid in the tympanic cavity, but either thickening of its lining membrane, or inspissated and altered secretion. In such cases paracentesis could do no good.—Mr. C. BROOKE said he was in 1817-18, the subject of that operation at the hands of Sir Astley Cooper. The operation was for deafness from enlarged tonsils, and was attended by complete relief. How long the openings remained patent he could not say.—Dr. C. BRANDEIS spoke in favour of the operation. A permanent opening might, if necessary, be effected by resorting to excision of a portion of the membrane. Not only is the division of the drum membrane seviceable in such cases in which there is a morbid secretion or an obstruction in the normal aeration of the tympanic cavity, but it is called for in cases where there is a disturbance of the natural contour of the membrane, or an anchylosis of the chain of bones, or an impaction of the stapes in the fenestrum rotundum. In these cases paracentesis of the membrane in the posterior inferior quadrant will serve to admit the sound waves directly into the tympanum, whence they can reach the lamina membranacea covering the fenestrum rotundum, and thus reach the labyrinth. The division of the membrane, however, is only of temporary service; it is necessary to maintain a permanent opening if any lasting improvement is to follow. This is best done by introducing a small aluminium canula, as recommended by Voltolini, a millimetre and a half in diameter, and from six to nine millimetres in length. The great difficulty met with is the tendency of the membrana tympani to throw off any foreign body, and this can best be obviated by a consideration of the configuration of the parts. At the proximal extremity of the external meatus there is a normal depression of the canal, and the distal end of the canula must rest in this depression, while the other end impinges upon the inner wall of the tympanic cavity, in order to prevent a displacement of the tube.—Mr. CUMBERBATCH agreed with Mr. Dalby as to the necessity of restricting the operation to cases of fluid accumulation in the tympanic cavity.—Mr. LENNOX-BROWNE was of a similar opinion, and that it was also applicable to the class of cases in which Dr. Purves had been most successful, namely, those of lax membrane which had been cured by cicatrices of repeated punctures.

SURGICAL SOCIETY OF IRELAND.

THE Eighth Meeting of this Society, took place on Friday evening, March 15th, 1878, Dr. COLLES, the senior member of the Council of the Society present, in the chair. The minutes of the previous meeting having been read by Mr. B. WILLS RICHARDSON and confirmed,

Mr. F. W. WARREN read a paper on

FRACTURE OF THE SPINE,

which will be found on page 291.

Mr. TUFNELL asked whether Mr. Warren had ever seen galvanism used in the treatment of bed-sores, because in cases of injury to the spine that was what he (Mr. Tufnell) had the greatest difficulty in contending with. He had never used galvanism himself, but he had seen sloughing going on in spite of everything he could devise, and in spite of the use of water-cushions from the first moment, and going on to such an extent that both trochanters were exposed, so that the patient could not be turned in bed.

Dr. O'LEARY wished to know what was the reaction of the urine, particularly immediately before death; also what was its specific gravity, and the amount of urea, as that information would be interesting in connection with the high temperature.

Dr. HENRY KENNEDY said that although he could throw no light on the cases, he might mention that in the "Clinical Reports" there were, to the best of his recollection, several cases, certainly some given, in which bed sores were treated by galvanism. By that means the sore was healed, but it broke out again and again, though still the galvanism was sufficient to heal it. The galvanism did not, however, alter the state of the parts sufficiently long to keep the sore permanently healed. In reference to the general question of temperature, it must not be forgotten that a large number of cases of medical disease gave rise to temperatures of a very considerable height. It would appear as if they were far more common in England than in this country, for they were constantly seeing details in the periodicals of cases where the temperature ran up to 109° and 111°. He had never seen a temperature of 109° in our city. He knew there were some cases on record, but they were exceedingly rare in comparison with England. In any explanation of the fact, then, they must take into account that those high temperatures were attained not after any injury, in the common sense of the term, but without any injury to the spine at all. Mr. Weir Mitchell, in his very interesting book (he did not know whether Mr. Warren alluded to that work in his paper), alluded specially to the treatment of some of those cases where the nerves were injured, and where galvanism was used with very good effect. It was certainly a means they should not overlook, especially where an illness was likely to be prolonged.

Dr. WARREN, in reply, said, with regard to Mr. Tufnell's questions, that he had never seen galvanism used himself in Steevens's Hospital or anywhere else. He merely had read of it, and seeing it backed up by such great authorities, and spoken of with such great emphasis, he thought it was worth mentioning. He was very glad that Dr. Kennedy had seen it do a great deal of good. With regard to the urine, the cases were so very acute, and death taking place in 34 hours and 24 hours after the receipt of the injury, he did not think it necessary to make a very careful examination of it, but he tested its reaction, and it was acid. To the eye it looked quite normal.

Mr. TUFNELL read a communication by Professor SEWELL, of Quebec, on

THE USE OF GREEN TEA IN COUNTERACTING POISONING BY OPIUM,

which will be found at page 275.

After having read the paper,

Mr. TUFNELL stated that Dr. Cameron, the city analyst of Dublin, had promised to undertake a series of experiments as to poisoning by opium, and the efficiency of green tea as an antidote. Perhaps on a subsequent occasion they would be able to learn what the result of Dr. Cameron's experiments on the lower animals had been.

Dr. HENRY KENNEDY said there were one or two points in connection with medical theories in the communication that he thought would mystify any person, and that prudence would therefore make them slow in accepting the

results set forth by the writer of the paper. In the first instance, the writer himself mentioned that to the best of his belief, the patient had taken 3¼ ounces of Battley's solution. That was not a positive fact—not such a fact as would satisfy them in accepting the whole of the conclusions based upon it. Three and a-half ounces of Battley's solution, which was known to be a very strong preparation of opium, was an enormous quantity. It did not appear, as far as he heard from the paper, that Professor Sewell had used an emetic or the stomach pump to clear out the stomach, and to suppose that 3¼ ounces of such a fluid should pass away, and allow the patient to recover without any real difference, was certainly a straining of anything they knew on the subject. There was another point, too, connected with the details of the case that he thought would also stagger most people—that was, the rapidity with which the patient recovered. It had been his lot to see several cases of poisoning--five or six—by opium, and even when they did recover the recovery occupied a very much longer time than that recorded in the case now under notice. This lady was seen first at 11 o'clock at night, and by 4 the next morning the symptoms had so far improved that the patient was recovering, and by 8 o'clock she was quite herself, as regarded danger to her life. That was not in keeping with what he (Dr. Kennedy) had seen of cases of the sort. They required very many hours before they recovered] Without throwing the slightest slur upon what had been detailed by the writer he (Dr. Kennedy) would try to explain the result of this case differently from what he had done. In reference to the antidote that was used, the late Dr. Maxwell published a paper many years ago, in which he recommended green tea for use in fevers. There was also a further contribution on the subject by Dr. Grimshaw, who gave a number of cases. He (Dr. Kennedy) had used it very largely, and it was a very useful stimulant in the low state to which fever brought a patient. Coffee had been long recommended for the antidotal effect it had on persons who had taken too much opium, and he need not tell this meeting that coffee and tea were precisely the same, except in this respect—that tea had a trifling quantity of thein that coffee had not. However, at the present day, he need scarcely mention that they had another antidote to which he imagined the gentlemen present would surely have recourse rather than to tea, with the slight experience that they had of the use of the latter at the present moment. He alluded to belladonna, which, in a case of poisoning by opium, should be used; and there were many cases—probably many of the members present knew of them—in which the specific effects of belladonna seemed to be very antidotal to those of opium, and he thought, with the knowledge that they had at present, that belladonna should be had recourse to before tea, after emptying the stomach by the aid of the stomach-pump. That should be the means adopt to counteract the bad effects of opium.

Dr. E. H. Bennett thought before the close of the discussion that it would be out of place to proceed further before he moved a vote of thanks to Professor Sewell for his communication, because, not being a member of the Society, and setting the ball going with reference to a new matter, they owed him certainly their thanks, whether they agreed with his opinions or not, or whether they could put those opinions to test if opportunity offered, certainly for his communication Professor Sewell deserved their thanks. He (Dr. Bennett) was entirely with Dr. Kennedy in his views. He thought the evidence before them was not sufficient to make them accept all the facts, and the same was the case with almost every case of recovery from poisoning put on record. With reference to the very matter to which Dr. Kennedy alluded, the relief of opium poisoning by atropia or by belladonna, the most recent cases—recorded within the last month—showed that enormous doses of atropia, to such a degree as Dr. Harley had pointed out—so far, at all events, as experiments were concerned—the combined effects would be poisoning, no matter whether given antidotally or not. He did not know anything of the effects of green tea. In conclusion he moved that the thanks of the Society be given to Professor Sewell for his communication.

Dr. Bigger had great pleasure in seconding the motion. He thought consideration ought to be made in Mr. Sewell's case for the period at which it was estimated the antidote was given, and the immediate effect it had in counteracting the poison. If he had waited until the case had progressed it would have been downright stupidity, and it would have been very difficult to bring anything to bear upon it. He had seen a case in which a gentleman suffering from stone in the bladder was in the habit of taking a certain quantity of drops made up in doses in ounce bottles. As he was going to the country suddenly, the bottle was sent to the apothecary, who returned it filled with laudanum. Unfortunately it was mistaken for one of the dose bottles, and the gentleman took the whole quantity, The effects of the laudanum were immediately produced, and stupidity to a frightful extent ensued, the patient falling about the room in the most helpless way. He, however, outlived the accident. Coffee was very largely used in the treatment of that patient—not by enema. He knew that turpentine was also used. The patient was put into a carriage and driven violently about and constantly kept in motion for a long time, although emesis did not occur for some time. The stomach-pump was used, but he did not think they got any laudanum from the stomach. When emesis did occur laudanum was smelt in the discharges. Although the patient recovered, he never was the same man again. There was another case in Dublin in which the sister of a gentleman of considerable notoriety in the city was in the habit of taking more than an ounce of laudanum every day. She lived a very long time. He treated her for some time, until he got wearied and tired, and felt that the patient was committing suicide under his auspices. She afterwards was in the hands of several other practitioners, but she ultimately died. The effects produced were very curious. She half slumbered during the day, but the moment night came on, and she got her dose, she had the people in the house running about in every direction to get impossible things, and that lasted until towards morning, when she got another dose. That lady went so far that the apothecaries refused to sell her laudanum, and she then made it herself.

Dr. Bennet—What did she make it of?

Dr. Bigger—Out of opium, I suppose. Dr. Bigger continued to say that there was another case in which a gentleman was in the habit of taking doses of solid opium in very large quantities. He had seen that man take six-and-twenty grains. He had seen him do it several times. He was now in a lunatic asylum. That man's case would be a very fit case, if he could be got at, for making some of the researches which had been proposed, and if he could be treated with green tea it would be a most excellent case. He was still living, and in very fair health, although he had been confined for several years. He had been a long time in an Eastern climate, and there acquired the habit of taking large quantities. He always carried it about in a box with him. Yet, at times that man was perfectly calm, quiet, and deliberate, and as full of mental energy as any one could be.

The resolution proposed by Dr. Bennett was then put from the chair, and passed by acclammation.

Mr. Tufnell, who replied on behalf of the author of the communication, said that with reference to the quantity of Batley taken, he might state that after Dr. Sewell had sent him the notes of the case he (Mr. Tufnell) thought it was very desirable to write them out, and to return them to Quebec for Dr. Sewill's revision before they were read before this Society, and Dr. Kennedy would observe that the quantity he (Mr. Tufnell) put down was three fluid ounces, and that Dr. Sewell had added "and a-half" afterwards. In a letter Dr. Sewell had written to him (Mr. Tufnell) he stated—"Your description from my notes is perfectly correct, with the exception that you are short by half-an-ounce of the quantity which was taken." What led Dr. Sewell to believe it was that quantity was from knowing what quantity was originally in the bottle, and what quantity was left. With reference to belladonna, they were aware of its influence in these cases, but the great point, and what was desirable in practice, was to have a remedy which was at hand, and which could be used. They knew very well that the public, even the profession, hardly knew how to use belladonna, and the way to give it as an antidote to opium; but they knew also that any old woman could make an infusion of green tea, and administer it per rectum. He was not really prepared to say what was the difference in the effect as between ordinary black tea and green tea. Dr. Cameron had, as he had said before, kindly offered to conduct a series of experiments, and to give the Society the results, and as the Professor of the Royal College of Surgeons in Ireland, and as public analyst of the City of Dublin, he (Dr. Tufnell) thought his opinion on the case would be very desirable. There was a great deal of argument now-a-days about green tea—whether it was prepared by being

done in copper vessels, and so on; but there was no doubt about this—that it was extremely stimulating.

Dr. B. WILLS RICHARDSON then read a paper on

EPITHELIOMA OF THE LOWER LIP,

which will be found at page 275.

The members having inspected the specimens prepared by Dr. Richardson,

The Society adjourned to the 29th ult., when the last meeting of the Session will be held.

THE SCOTTISH UNIVERSITIES.

THE Royal Commisioners appointed to inquire into the Universities of Scotland have issued their report, which is the result of their having held 93 meetings and examined 112 witnesses. The following is a summary of their recommendations as regards the medical departments of these corporations:—

That every candidate for a degree in Medicine shall, before commencing his professional course, be required to pass the "First Examination" with the modifications stated in paragraph 14, and shall thereafter devote not less than four years to the course of professional study at present prescribed.

That no candidate for a degree in Medicine shall be admitted to examination in Human Anatomy or Physiology, or in any purely medical subject, unless he has passed an examination in Natural Philosophy, Chemistry, Physiology, Botany, and Zoology, as constituting the second and third groups of the fifth or Natural Science department for the degree of M.A

That the final examination for the medical degree shall be confined to the practical subjects of Medicine and Surgery, both systematic and clinical, Obstetrics, Pathology, Therapeutics, Medical Jurisprudence, and Hygiene; and that no candidate shall be admitted to examination in these subjects unless he has passed in the other subjects of the medical curriculum.

That the degree of Bachelor of Medicine shall not be granted without a degree in Surgery, the degree to be granted in Surgery along with the Bachelorship of medicine being that of Bachelor in Surgery (Ch. B.) which has been recognised as a registrable title by the Medical Practitioners Act, 1876; and that the examination fees to be paid by candidates for the double degree shall be 20 guineas (£21), to be paid in instalments at different stages of the candidate's examination.

That the degree of Master in Surgery (C.M.) shall be made attainable separately at a future time, under similar conditions to those which now apply to the degree of Doctor of Medicine (M.D.)

That for the degree of Bachelor of Science (B.Sc.) every candidate shall be required to pass the "First Examination," with the same options as those which apply to candidates for degrees in Medicine; and that, after passing that examination, he shall be required to attend and to pass an examination in either (1) courses in the subjects included in the fourth or Mathematical Science department for the M.A. degree, and also the subject specified in the second group of the fifth or Natural Science department for the same degree; or (2) the courses specified in any three of the groups of the fifth or Natural Science department.

That while no entrance examination, a failure to pass which would exclude from the University, ought to be instituted, it shall be the rule of the University that no attendance by a student given before passing the "First Examination" shall be available for any degree; but that a power of dispensing with this rule in cases where the circumstances may seem to justify the relaxation shall be reserved.

That in the University of Glasgow a new professorship shall be instituted—viz., a professorship of Pathological Anatomy in the Faculty of Medicine, and a lectureship on Mental Diseases.

That in the University of Aberdeen a new professorship shall be instituted of Pathological Anatomy in the Faculty of Medicine; and that there shall also be instituted a lectureship on Mental Diseases.

That in the University of Edinburgh the name of the chair of General Pathology in Edinburgh shall be changed to Pathological Anatomy; and that a lectureship on Mental Diseases shall be instituted.

That the following provisions for assistance and apparatus shall be attached to different chairs in the Universities of Edinburgh, Glasgow, and Aberdeen, viz.:—To the chair of Institutes of Medicine or Physiology, two assistants, one at £150, and the other at £100 a year: also a sum of £1,000 for the purchase of apparatus and material of a permanent kind, with an annual sum of £100 for the maintenance and provision of new material. To the professorship of Botany, two assistant demonstrators at £100 each, if the class numbers as many as a hundred; any additional demonstrators beyond two, if required by the size of the class, being provided by the professor; and, if the class does not much exceed fifty, one assistant demonstrator being sufficient. To the professorship of Pathological Anatomy, an assistant at a salary of £100. To the professorship of the Practice of Physic, an assistant at a salary of £50; and to the Professor or Professors engaged in clinical instruction at the infirmary a clinical tutor at a like salary; also for the two professorships of Pathological Anatomy and Practice of Physic an annual sum of £100 for the maintenance of a joint class museum. To each of the professorships of Surgery and of Clinical Surgery (where such a chair exists), an annual allowance of £50 for the purchase of instruments and mechanism; and for the Professors engaged in clinical instruction in Surgery at the infirmary a clinical tutor at a salary of £50.

That, as far as possible, and subject to exception where a Professor's teaching duties are very light, as well as where the Professor properly associates professional practice with the discharge of his academic duties, provision shall be made whereby the emoluments of a Professor shall not be less than £600 a year; the endowment of any Professor whose emoluments are now less than that sum being fixed at such an amount as with his estimated probable income from fees may bring up his total emoluments to not less than £600 a year.

That in each of the Universities of Edinburgh, Glasgow, and Aberdeen, the salary of the Principal shall be increased by £200, so as to raise the salary in each of the former Universities to £1,200, and in Aberdeen to £800 a year.

That the conditions of retiring allowances to Principals and Professors retiring on the ground of age or infirmity shall be revised to the effect—(1) Of allowing an addition of fifteen years instead of ten as at present, to the actual period of service in computing the amount of retiring allowance. (2) Of allowing a Principal or Professor, at an age of sixty-five, to retire on the retiring allowance applicable to his period of service, without the necessity of his producing a medical certificate of incapacity. (3) Of reckoning each academical year of service as a year in computing the years of service. (4) Of allowing years of service in any of the Queen's Colleges in Ireland to be reckoned by a Professor who has held office there previously to becoming a Professor in Scotland.

THE annual death-rate last week in the four principal cities of the United Kingdom were—London 24, Edinburgh 26, Glasgow 29, Dublin 32 per 1,000 of the population. Plymouth still maintains the highest rate in the United Kingdom, viz., 34 per 1,000, the excess being chiefly attributable to whooping-cough.

ST. PETERSBURGH has still the highest death-rate in Europe, the mortality last week being 60 per 1,000 of its population. Out of 776 deaths, the enormous proportion of 180 occurred from typhus and enteric fevers. Munich is next highest with 45, Rome 41, Buda-Pesth 40, Venice 35, Turin 34, Vienna 33, Brussels 33, Rotterdam 30, Geneva 29, Paris 27, New York 25. Of the Indian cities Madras shows a death-rate of 84, Bombay 46, and Calcutta 31 per 1,000.

A PUBLIC meeting in aid of the London Hospital will take place to-morrow, under the presidency of the Lord Mayor, who will be supported by the Duke of Cambridge, the Duke of Westminster, and other persons of distinction.

REGISTERED FOR TRANSMISSION ABROAD.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, APRIL 3, 1878.

WILLIAM HARVEY.

MONDAY, the 1st of April, was the 300th anniversary of the birth of William Harvey, the discoverer of the circulation of the blood; and we should be wanting in respect for that great name if we did not make a few remarks in acknowledgment of the claims he has upon our memory.

Several incidents have lately occurred to direct more than ordinary attention to Harvey's valuable discovery. Only a few months ago the original notes of the first lectures which he delivered in the College of Physicians in 1616, as Lumleian Lecturer on Anatomy and Physiology, were re-discovered in the British Museum. Soon after that event Dr. Sieveking delivered his able and learned Harveian Oration, in which special allusion was made to these precious manuscripts; while still more recently we have had Professor Huxley's lucid and popular exposition of the originality and unrivalled merit of Harvey's great discovery. Unfortunately there has been another memento of a less pleasing nature. There have not been wanting those who have detracted from the fame of the great physiologist. He has, in fact, in this respect shared the fate of many other great men; and just as Bacon's reputation as a philosopher has not escaped the captious animadversion of his critics, so that his claim to be the apostle of the inductive or experimental philosophy has been disputed, and he has been called an "impostor" in respect of his scientific pretensions, in like manner there have been those who have questioned the merit of Harvey as a great discoverer, and have refused him that great honour which has been accorded to him by the all but unanimous assent of the civilised world. Only last year we were all startled by the announcement that on Oct. 30th a monument of Andrew Cesalpino was unveiled at Rome, on the ground of his being the first discoverer of the circulation of the blood. Dr. Guilio Ceradini, Professor of Physiology at Genoa, asserted on that occasion that Cesalpino produced experimental proof of the circulation in 1593, and that Harvey's merit only consisted in having sustained a battle against ignorance and prejudice by divulging the discovery of Cesalpino. Fortunately, however, for Harvey, his fame rests upon too strong a foundation to be even shaken by the rude shocks of his detractors. While the latter may be counted on the fingers, his defenders are innumerable. The unanimous voice of his own countrymen, the testimony of his most respected contemporaries, and the all but unanimous assent of foreign nations, are the best guardians of his fame; and he is more to be envied for the unapproachable position he holds at the present day among great discoverers, than to be pitied for the petty jealousies and criticisms that his great reputation has in a few instances excited. We were reminded by Dr. Sieveking of some of the great men who readily acknowledged Harvey to be the real founder of the doctrine of the circulation. The celebrated Descartes, in 1637, spoke of the English physician as a man to whom the world was indebted for this knowledge. Professor Waldæus in Leyden, in 1640, Joannes Trulsius in Rome, in 1651, and Plempius in Louvain, in 1652, supported the new doctrine. The learned Schlegel makes the same admission, and says that having been in familiar intercourse with the most distinguished anatomists of Padua, Venice, and throughout Italy for some years, he had found "the movement of the blood almost entirely unknown, or that it was certainly regarded as incredible." Later on, Flourens, in his "Histoire de la Circulation du Sang," says that when Harvey appeared, all was hypothesis and conjecture; nothing was established.

It must, however, be admitted that there have been few great men whose discoveries in science have not been based upon some previous knowledge of the subject. As Dr. Whewell as shown in his "History of the Inductive Sciences," there have been few discoveries in physics, in astronomy, in geology, in botany, and in physiology, which had not their "preludes," and which were not foreshadowed, or even partly anticipated by some able but less successful, labourer in the field of science. As long ago as 300 years B.C., Erasistratus laid the foundation of the theory of the blood by his discovery of the valves of the heart. He noticed that this organ was furnished with valves which admitted of the blood flowing in one direction, but not in another. He did not, however, make any further advance; and observing that the arteries were usually empty after death, he fell into the error of supposing this was their normal condition, and that during life they are filled with air. More than 400 years afterwards, the celebrated Galen, whose great genius and anatomical labours have earned for him the reputation of being the founder of experimental physiology, not only showed by experiments on living animals that the arteries are as full of blood during life as the veins are, but he almost entirely demonstrated the pulmonary circulation. He correctly asserted that the ramifications of the pulmonary artery in the substance of the lungs communicated with those of the pulmonary veins by direct, though invisible, passages, called by him anasto-

moses ; but he supposed that a large part of the blood in the right ventricle passes directly through certain invisible pores in the septum, into the left ventricle. He thus knew that the blood passes from the right side of the heart, through the lungs to the left side, and that, moreover, it undergoes a great change in quality and in colour, brought about by its relation with the air in the lungs. But while he had a very good idea of the pulmonary circulation, and some conception of the process of respiration, he knew nothing about the systemic circulation. Nor did the great anatomists who lived in the fifteenth and the beginning of the sixteenth centuries, add much to what was previously known respecting the functions of the heart and great vessels. Vesalius added much to our knowledge of the structure of the human body, but he did nothing towards removing the prevailing errors respecting the movements of the heart and of the blood. Servetus did little more than confirm the doctrine of Galen with regard to the pulmonary circulation, and the first anatomist that declared that the septum of the ventricles is imperforate, and that all the blood of the right ventricle traverses the lungs in its passage to the left ventricle, was Realdus Columbus, Professor of Anatomy in the School of Padua. Columbus, therefore, as acknowledged by Ambrose Parè in 1579, was the first to establish the existence of the pulmonary circulation, in the modern sense of that term ; and, as Professor Huxley very justly remarks, he was the only physiologist, between the time of Galen and that of Harvey, who made any important addition to the theory of the circulation. For so far was Cæsalpinus from anticipating Harvey's great discovery, that he did little more than reiterate the teachings of Columbus. Dr. Sieveking observes, that Cæsalpinus was not himself conscious of having made any discovery, "for he introduces the subject of the circulation incidentally in a chapter headed, *Cor non Solum Arteriarum set et Venarum et Nervorum Principium*, and nowhere lays stress upon what is now claimed as his prerogative." Nor did the contemporaries of Harvey have a clear idea of the systemic circulation. The most celebrated of them, Van der Spieghel, or Spigelius, taught that the pulsation of the arteries had an effect in promoting the motion of the blood in the veins, but this was the only fresh step that was made towards arriving at the truth. "From Galen to Spigelius," says Professor Huxley, "they one and all believed that the blood in the vena cava and its branches flows from the main trunk towards the smallest ramifications," and that most of the blood distributed by the veins is derived from the liver. "According to the view of Harvey's predecessors, the veins may be compared to larger and smaller canals, fed by a spring which trickles into the chief canals, whence the water flows to the rest. The heart and lungs represent an engine set up in the principal canal to aërate some of the water and scatter it all over the garden. Whether any of this identical water came back to the engine or not would be a matter of chance, and it would certainly have no sensible effect on the motion of the water in the canals. In Harvey's conception of the matter, on the other hand, the garden is watered by channels so arranged as to form a circle, two points of which are occupied by propulsive engines. The water is kept moving in a continual round within its channels, as much entering the engines on one side as leaves them on the other ; and the motion of the water is entirely due to to the engines."

Professor Huxley, from whose able disquisition we have made the above quotation, alludes to the controversy there has been respecting the method by which Harvey obtained the results which have made his name famous. Those who have advocated the propriety of scientific men making more use of the deductive method of reasoning than they are in the habit of doing, have contended that Harvey discovered the circulation of the blood by reasoning deductively from the disposition of the valves of the veins. Unless we are mistaken, Buckle, in his "History of Civilisation," shares this opinion, no doubt influenced by a conversation that took place between Robert Boyle and Harvey himself. Professor Huxley, on the other hand, only allows that Harvey was "induced to think of a circulation of the blood" by considering the disposition of the valves of the veins, and denies that Harvey reasoned out the circulation from the datum of the veins. In order to show the justice of his views, the Professor quotes at length that celebrated passage which contains the fullest account of the considerations which led to the doctrine of the circulation. In our opinion, however, this very passage shows that if Harvey did not reason out the circulation from the datum of the valves only, he reasoned from other previously established facts in a manner that warrants us in concluding that the *theory* of the circulation flashed across his brain in consequence of his *deductive* reasoning, and that what was for a time a theory was afterwards shown by experiment, by *inductive* reasoning, to be a great reality. Want of space will not permit of us mentioning these data, but the last sentence of this well-known passage is very significant. He says, "So I began to think whether there was a kind of motion, as it were, in a circle ; this I *afterwards* found to be true." The question, however, is not one of much importance. Deductively or inductively, William Harvey made a grand discovery, and laid posterity under obligations, which even we, at this distance of time, gladly acknowledge—a discovery which will continue to awake the admiration and the gratitude of generations to come, as long as medicine is studied as a profession and physiology as a science.

THE ARMY MEDICAL DEPARTMENT.

Mr. Hardy's parliamentary utterances have made it sufficiently obvious that the state of the Army Medical Department is, confessedly, one of disorganisation. The War Secretary has adopted a very frank and honest course under the circumstances. He has applied direct to those who are in contact with the student, asking advice from them as to the causes of the unpopularity of the service. The letter thus addressed to the Medical Schools is as follows :—

War Office, 21st March, 1878.

Sir,—I am directed by Mr. Secretary Hardy to acquaint you that it has been brought to his notice that a great unwillingness to compete for commissions in the Army Medical Department has for some time existed on the part of Medical Students, and this, notwithstanding that many measures for the improvement of the Department have been introduced by Mr. Hardy and his predecessors. Mr. Hardy is most anxious

to place the Department in such a condition as to attract the best candidates in the profession—and with this object in view he will be much obliged if you will favour him unreservedly with the opinion of the Royal College of Surgeons, Dublin, as to the specific causes which produce the existing difficulty in obtaining candidates for the Department.

I am, Sir,

Your obedient servant,

Signed RALPH THOMPSON.

At the present moment the schools are engaged in considering their reply. The Royal College of Surgeons in Ireland has appointed a committee to consider and report to the Council on the subject, and that committee has taken steps to ascertain the actual opinion of the Army Surgeons themselves in a manner which will leave no room for doubt as to their feeling on the subject. They have issued to them the following circular :—

SIR,—The President and Council of the Royal College of Surgeons in Ireland, being desirous of learning the actual state of feeling now existing in the Army Medical Service relative to the Unification and Regimental systems respectively, have considered that the best way of ascertaining the same would be by ballot.

I am therefore directed to enclose to you a Voting Paper, and the President and Council will feel obliged by your kindly putting a X before the system (Unification or Regimental) which you yourself prefer, and which you think will induce the best men to enter the Service, and to forward the same paper to me in the enclosed envelope by return of post, if possible.

Should you also desire to offer any suggestions for the improvement of the Army Medical Service, or to point out any abuses which you feel to be now existing in it, the Council will be glad to receive the same; and as the sources from which such information is derived will be totally unknown, you may without hesitation *unreservedly* give your opinion and experience to the Council for their guidance.

I remain, &c.,

Your obedient Servant,

J. STANNUS HUGHES,

Secretary, Royal College of Surgeons in Ireland.

We apprehend that the Secretary for War will learn from the replies to his letter more than he has ever known respecting the feeling of the Army Medical Officers and the causes of abstention of students. Without doubt, the three principal causes are :—*a*. The Short Service System. *b*. The abolition of the system which associated the doctor with his brother officers. *c*. The uncertainty of tenure and of position which has been created by the frequent violation of the warrants. The Unification System must—we imagine—be taken as inevitable, but the Ten Years' System must be got rid of if the Service is to be recognised.

LUNACY IN ITS RELATIONS TO THE STATE.

LAST year a Select Committee of the House of Commons was appointed to inquire into the operations of the Lunacy Laws, so far as they afforded security against violations of personal liberty. A large number of witnesses were examined; but so voluminous, and, in some respects, so contradictory was the evidence received, that the publication of the Report of the Committee was deferred to the present year. That Report is not yet published, and while we, in common with the general public, are anxiously waiting for its appearance, our attention is drawn to a pamphlet in which the author, Sir James Coxe, M.D., F.R.S.E., Commissioner of Lunacy, Scotland, has endeavoured to bring into clearer relief the more valuable portions of the evidence on which the Report will be based.

The subjects brought before the notice of the Select Committee were so numerous that we can only briefly remark on those on which the question at issue chiefly turns, and which most directly affects the interests of the public. These questions have reference to the kind of supervision the State has, first, over the admission of lunatics into public and private asylums; and, secondly, over their detention after admission. Now, the State supervision with regard to the admission of patients into asylums (public and private) differs in England and Scotland. In England, observes Sir James Coxe, no judicial authority is necessary for the purpose, the action of the relieving officer, with the perfunctory assistance of a justice or clergyman being, along with one medical certificate, all that is required for the purpose in the case of paupers; while, in the case of private patients, two medical certificates and a request for admission by a relative, or, indeed, by anybody, fulfil all the requirements of the law. In Scotland, on the other hand, an order by the sheriff is required for the admission of private and pauper patients alike, and two medical certificates are necessary in both cases.

Before, however, we compare the relative merits of these two systems, we must dwell a little on the subject of medical certificates, about which there has been almost as much discussion and as much difference of opinion as on any question of lunacy. For the question has been very generally raised, whether it should be in the power of anyone to place a relative or friend into an asylum on the certificates of two medical men, whose only qualifications may be that they are both duly registered practitioners. Consequently, some of the witnesses examined by the committee, advocated the appointment of skilled experts, who should be deputed to examine all alleged lunatics, and determine whether they were or were not insane. Now independently of the practical difficulties there would be in the way of carrying out such a plan, and the delay there would often be in securing the attendance of the expert, there are good reasons for approving of the confidence which the State has hitherto placed in the evidence of the ordinary physician or practitioner. For a very significant fact in favour of the present system, is that those very witnesses who recommended the employment of skilled experts, were obliged to admit that cases in which a sane person had been dealt with as a lunatic were exceedingly rare; so rare that men with large opportunities of observation could scarcely recall a single case. It cannot, therefore, be contended that the present law with regard to the signing certificates of lunacy has in any appreciable degree jeopardised the liberty of the subject. It may even be doubted whether the appointment of experts would not do more harm than good. Lord Shaftbury's opinion, as quoted by Sir James Coxe, is on this point very decided. "I confess," he said, "I should be very much alarmed if special doctors of that kind should be instituted. They would so completely surrender everything to science, that they would take leave of common sense . . . . . you may depend upon this if ever you have special doctors, they will shut up people by the score." This observation is certainly not very complimentary to a class of specialists whose experience and learning should claim for them a more respectful opinion; but his lordship's sarcasm is not altogether unwarrantable, even on the sup-

position that nearly all the cases of alleged lunacy that come up for examination are of a very doubtful nature. For the mind of the expert being biassed by opinions and impressions which long devotions to one pursuit has engendered, his judgment might often be less sound and practical than that of the ordinary practitioner, who, taking a more comprehensive, practical, and common sense view of the case, would be more likely to give the patient the benefit of the doubt, and consequently secure his personal liberty. But are these cases, as a rule, of a very doubtful nature? We all know that they are not. Generally speaking, when medical men are called upon to sign these certificates, the symptoms of insanity are so evident that few people could mistake them; and where there is any doubt, the penalty which the medical attendant knows he is exposed to by making a mistake, usually induces him to decline all responsibility in the matter, and to request the relatives of the patient to have a higher opinion. Besides, it should be borne in mind that every year, as the standard of medical education improves, the ordinary practititioner will be more and more fitted to make a correct diagnosis, even in the more doubtful forms of insanity. Some time ago, in an article on the Study of Psychological Medicine, we urged the necessity of making this study a part of the medical curriculum of the student, or, at least, of its receiving more consideration from the lecturers on medicine than is usually accorded to it. This step has indeed already been partly taken, and students have inducements held out to attend lectures on Psychological Medicine, as well as to attend the practice of some asylum. If, therefore, when the study of insanity formed no necessary part of medical education, the committal of sane persons to asylums was, nevertheless, a matter of exceedingly rare occurrence, how much less likely is such a mistake to be made, and how much less reason will there be for the State to delegate to experts an office which has been hitherto entrusted to the ordinary practitioner, when a knowledge of insanity is demanded of every candidate that presents himself for a license to practise medicine.

We may therefore venture to question whether the Select Committee will, in their forthcoming Report, think it advisable to make any change with respect to the class of practitioners by whom certificates of lunacy should be signed; but we have still to consider whether the other provisions relating to the admission of lunatics into asylums are more open to criticism, and in what way they might be altered for the better. In the first place, the very fact of these provisions differing, as we have seen, in England and Scotland, appears to us a serious objection; for surely in such an important matter as that of placing patients in asylums, there should be some uniformity in the procedures adopted in both countries. With regard to the relative merits of the English and Scotch systems, the evidence given before the Select Committee does not afford much ground for decision. Of the witnesses questioned on the point, those residing in England were in favour of the English system, while the Scotch witnesses were in favour of their own; but, as Sir James Coxe justly remarks, the opinions taken were those of persons concerned in administering the statutes, and not of members of the general public, whose persons and interests are disposed of under them. If the question were put to the latter under which system they would prefer to be dealt with, the answer, in the judgment of the above physician, would be under the Scotch system. Nor are we disposed to differ from him in this opinion, for the procedure adopted in Scotland seems, as far as the interests of the patient are concerned, to have certain advantages over the English practice. The course pursued in Scotland is the same for all classes of patients. An order by the Sheriff is required for the admission of private and pauper patients alike. Two medical certificates are necessary in both cases. A patient may be received into an asylum on what is called a certificate of emergency, which may be granted by any one medical man, and even by the medical officer of the asylum, and which is in itself sufficient authority for detention for a period of three days. Whereas, moreover, in England no limit is placed to the duration of the order, in Scotland it runs out in three years, and is then only continued in force by the declaration of the superintendent of the asylum that he has fully considered the case of the patient, and is of opinion that further detention is necessary. By this declaration the sheriff's order acquires renewed authority for another year, at the expiration of which the medical officer of the asylum is again called upon to certify to the necessity of continued detention, and this certificate has to be repeated every year so long as the patient is detained. It is obvious that the interests of the patient and his relatives are more considered in the above system than in that pursued in this country. The certificates of emergency not only afford security against undue haste in having recourse to permanent asylum treatment, but it obviates the objection to the sheriff's order, which, coupled with the fact that it only holds good for three years, and has to be reinforced by a proper certificate every year afterwards, is calculated to inspire the public with confidence in the assurance that no one can be deprived of his liberty unless upon grounds sufficient to command the acquiescence of a high legal authority. This supervision of the certificates by the sheriff may be said to have its counterpart in the same supervision by the English Lunacy Board, but then it must be borne in mind that the inspection of the English Commissioners is not made till after the patients have entered the asylum; and considering how desirable it is to avoid if possible "the brand of lunacy," the examination of the certificates by the sheriff before admission is, as Sir James Coxes justly urges, a preferable procedure to the examination by the Commissioners after the patient has been admitted and proclaimed a lunatic.

From the foregoing facts, however, and more especially from the circumstance that the committal of sane persons to asylums is of exceedingly rare occurrence, it is evident that the personal liberty of the subject is not in much risk of being violated through the present provisions of either the English or Scotch lunacy law with regard to the *admission* of patients into lunatic asylums. It is not, in our opinion, of the course now pursued before the lunatic is admitted into an asylum, that the Select Committee will report so unfavourably, but rather of the provisions of the law with regard to the supervision of patients during their detention in the asylum. It is questionable whether in the former case any very material alterations will be deemed advisable; but with regard to the limits of

detention, and the safeguards of patients after they have entered an asylum, the present law is, as we shall hereafter see, more open to objection; for insanity may last many years, "and there is no statutory provision under which a patient, unless his recovery is absolute, must necessarily regain his liberty, or even have his case brought under review."

Notes on Current Topics.

Apothecaries' and Other Weights.

THE Weights and Measures Bill prepared by the Board of Trade, and now before a Select Committee of the House of Commons, is a much-needed consolidation of the many Acts or parts of Acts in the British code which relate to weights and measures. It proposes to repeal, and practically to re-enact in one, the whole or sections of twenty-two acts from Magna Charta downwards. It is reviewed by the *Chemist and Druggist* which points out that the majority of the provisions of the Bill do not greatly concern chemists and druggists generally, but considers that an unnecessary confusion has been occasioned by what seems to us the insufficiently-considered opposition which the Pharmaceutical Council has seen fit to offer to the desire of the Board of Trade to abolish the apothecaries' weight. The grain, as the 1-7000th part of an avoirdupois pound, is now a recognised weight. The troy ounce of 480 grains, which is the same as the apothecaries' ℥, is to be retained. What more is needed? Quinine and some other medicines, it is said, are sometimes asked for by the drachm or scruple. Surely they could be sold by the 60 or 20 grains. The absurdity of having among our weights two quite different drachms, one being the 16th part of an avoirdupois ounce and the other rather more than double that value, is not worth perpetuating. The signs ℈ and ʒ might be legalised to represent 20 and 60 grains respectively, and thus, as we conceive, all inconvenience would be obviated. The Bill, as it now stands, however, is rather indistinct on this point. The preliminary memorandum says that, "By 5 and 6 Will. IV. c. 63, s. 10, all articles sold by weight were required to be sold by avoirdupois weight, except gold, silver, and precious stones, which, under 16 and 17 Vic. c. 29, s. 1, are to be sold by the troy ounce, or by multiples or decimal parts of that ounce, and except drugs, which, when sold by retail, may be sold by apothecaries' weight; a weight with respect to which no enactment is made." Clause 20 of the proposed Bill requires that all articles sold by weight shall be sold by avoirdupois weight, except (1) gold, silver, platinum, precious stones, &c., which *may be* sold by troy weight, and (2) drugs, by retail, which *may be* sold by apothecaries' weight. They *may* also, we presume, be sold by avoirdupois weight, so that if we go to a shop and ask for an ounce of diamonds the jeweller may legally give us 437½ grains, or 480 grains, as he may think best.

FOOT-AND-MOUTH disease is prevalent among the swine in Berlin to such an extent, says the *Veterinary Journal* for April, that in one week more than a thousand head were compulsorily slaughtered by order of the veterinary inspectors.

The New Sydenham Society's Publications.

WE noticed recently the issue by the Society of Dr. Neale's "Medical Digest," the publication of which we conceived to be essentially the work of such a society. We are glad to observe by the Annual Report that another very important work of the bibliographic class was offered to the Council by Dr. Waring, and has been accepted, and is in course of printing. Under the title of "Bibliotheca Therapeutica," Dr. Waring has compiled a synopsis of the literature of therapeutics and materia medica, classified, first, alphabetically, and secondly, according to subject. The titles of all works, and their place and date of publication, are given with, in many instances, a short abstract or descriptive reference. These, works between nine and ten thousand in number, divided into sections and arranged in chronological order, constitute an instructive history of therapeutics and materia medica from the introduction of printing to the year 1875. The author mentions the public libraries of Great Britain where copies of most of these works are to be found.

Without making any absolute pledge as to those which will be issued in 1878, the Council mention as probable the following:—Dr. Waring's "Bibliotheca Therapeutica," the third volume of Smellie, the second fasciculus of the "Atlas of Pathology," and the second series of Charcot's "Lectures." Should the accession of new members be large it is quite possible that the Society's funds may afford a fifth issue in one or both of the years 1877 and 1878, and if that is the case the first part of Mayne's "Lexicon," the second volume of Latham's works, and Dr. McDonnell's edition of Colles' works, will probably be available.

The Weather and Victims to Fashion.

IT is not generally known, even to members of the profession, that the present fashion in ladies' dress has, at this season of the year, much to do in the causation of the severe colds, sore throats, and rheumatism that are now so prevalent. There is no disguising the fact that one object of the present mode of dressing is to show the figure to more advantage than was formerly attainable under the old system of hoops, crinoline, stiff petticoats, &c.; and so far as the present style of dress is in more conformity with the natural shape of the body, we may congratulate the fair sex on the change that has taken place. From a hygienic point of view, however, the extent to which some would carry the present fashion is a strong temptation to discard that warm clothing which is so often indispensable in a treacherous climate like ours. Quite recently, we have been called to two cases, one of severe "cold," and one of rheumatism, in both of which the affection was owing to the patient having left off a portion of her dress with the view of more strictly conforming to the dictates of fashion. It is also a fact, not generally known, that the young ladies who officiate in the costume departments of our great drapers' establishments, are restricted to the smallest possible underclothing in order that their customers may see to advantage the dresses that are tried on. We venture to draw the attention of our readers to these facts, in the hope that young women will not be tempted to sacrifice their health to their vanity and love of dress.

Government Grants for Research.

Amongst the grants to be paid from the Government fund of £4,000, on the recommendation of the Royal Society, within the present year, we find the following :—

W. Saville Kent, St. Heliers, Jersey.—To pay for Microscopical Apparatus for the Further Prosecution of Investigations into the Structure and Life-History of certain Lower Protozoa - - - - - - - £50

Dr. W. A. Brailey, 38 King's Road, Brownswood Park, Green Lanes, N.—For Researches on the Causes determining the Tension of the Globe of the Eye in Man and Animals, and on the Physiological Influence on this Tension of such substances as Atropia, Daturin, Eserine, and Pilocarpine - - - - - - - £25

Dr. C. R. A. Wright, St. Mary's Hospital, Paddington.—For Continuation of Researches on Certain Points in Chemical Dynamics ; on the Determination of Chemical Affinity in Terms of Electrical Magnitudes ; and on some of the lesser-known Alkaloids - - £100

Also "personal" grants to—

Prof. W. K. Parker, 36 Claverton St., S.W.—For Assistance in Continuation of Researches on the Morphology of the Vertebrate Skeleton and the Relation of the Nervous to the Skeletal Structures, chiefly in the Head £300

Prof. A. H. Garrod, 10 Harley Street, W.—For Aid towards Publication of the Second Fasciculus of an Exhaustive Treatise on the Anatomy of Birds - £100

Also to Drs. Brailey and Wright for the same purposes as noted above, £25 and £200 respectively.

Tests of Endurance.

The recent extraordinary pedestrian competition at the Agricultural Hall, has given rise to a spirit of inquiry amongst scientific men, and even by Her Majesty's Government, which may eventuate in statistics of considerable value from a military point of view. The Anthropometric Committee under the direction of Dr. Farr, are particularly desirous of obtaining measurements of persons engaged in athletic sports ; and we understand that Mr. Gant, who was professionally engaged to examine the men during the recent six days walking match, has been asked to assist the committee in their investigations.

Oxygen in Sea Water.

Mr. J. Y. Buchanan, the chemist on board the *Challenger*, gave an account of his experiences to the Chemical Society on February 21. The most interesting discovery he made seems to have been the fact that the proportion of oxygen in the sea gradually decreases down to a depth of 300 fathoms, and from that point to the bottom it gradually increases. It is as well that every little scrap of information furnished by the officers of that scientific trip should be carefully preserved, for the country had to pay pretty handsomely for it, and the total results have not yet startled the world.

Extract of Pimentum as a Counter-Irritant.

This preparation has been lauded by some French physicians as a valuable revulsive, not being so fugacious as mustard, nor so irritating as antimony or croton oil. It begins to act in from ten to thirty minutes, according to the delicacy of the skin, causing heat, a slight tingling and redness, which go on increasing for about three hours, when they remain stationary. The plaster may be applied for eight to ten hours in children, and for twenty to twenty-four in adults. No great irritation capable of impeding occupations ensues, and it may be best compared with that of a sinapism arrived at half its power, and so maintained for the twenty-four hours.

Lectures on Heart Diseases.

We give in our present issue an abstract of the first of a series of lectures just commenced at the West London Hospital, by Dr. Milner Fothergill, no mean authority on the subject of heart diseases. The first lecture is on "Valvulitis," and the remainder, which will be delivered each alternate Wednesday, from April 3rd until May 1st, at 3 p.m., will be on "Hypertrophy and Dilatation," "The Gouty Heart and Fatty Degeneration," "The Neurosal and Reflex Disorders." The course is open free to medical men and students on presentation of card. We hope te lay copious abstracts of the entire series before our readers, and doubt not they will be appreciated.

At the last Antrim Assizes Dr. Spearing, of Antrim, sued Dr. Killen, of the same place, to recover the sum o £114 for medical services. It appeared from evidence that Dr. Killen, defendant, sustained an accident in December last, which occasioned a severe fracture of the leg, and was caused by a collision on the Northern Counties Railway line, near Antrim. Plaintiff paid 119 visits to defendant. For defendant it was contended that a large number of unnecessary visits were paid, and that some were friendly visits, for which no charge should have been made.

His lordship said it appeared from evidence that defendant had received as compensation for his accident the sum of £3,250 from the railway company, and also that when the company awarded to him that sum they had before them the account of plaintiff, and consequently made allowances for his services.

The jury found for plaintiff the full amount claimed.

The Pharmaceutical Society of Great Britain has just issued an excellent catalogue of the fine collections of Materia Medica and chemical products in their museum in Bloomsbury Square. The catalogue is the work of the Society's Curator, Mr. E. M. Holmes, F.L.S., and includes a great deal of information regarding the several products mentioned. The alphabetical classification of the plants according to their genera in each order, and the numerous references to figures in English, American, and foreign works, will make this book valuable, not only to students of the collection it illustrates, but also for handy reference on the subject generally.

An individual, named Charles Cherwood, representing himself as an American physician, has been arrested in London, on a charge of forging amounts on cheques by means of chemicals. Prisoner's *modus operandi* is very simple. He purchases goods to a small amount for which he pays in bank notes, asking for the change in a cheque. Having thus obtained the *bonâ fide* signature of a firm, he obliterates with chemicals the small amount thereon, filling in the line for hundreds of pounds. In one case he succeeded in obtaining £500 on a cheque which was

originally filled in for £5 only. It is now thought that the ranks of the profession in America will be *minus* one member for some time to come.

THE Chair of Dermatology at the Royal College of Surgeons, England, created by the munificence of Professor Erasmus Wilson, F.R.S., and subsequently held by him, has become vacant by the resignation of that gentleman. It is generally understood that Mr. Jonathan Hutchinson will be his successor, than which, a more acceptable choice could scarcely be made.

FORTY-TWO deaths occurred from small-pox in London last week, being fewer by eleven than the previous week. Of these, 30 occurred in public institutions, and 12 in private dwellings. Whooping-cough is, at present, the most fatal of the zymotics in London, 124 children having died from this cause last week. With these exceptions, the mortality is much lower than the average of this season of the year.

BY telegram we learn that typhoid epidemics have been carried from the seat of war into the interior of Russia, where the population of several towns and localities have been almost decimated by infection.

DR. FORBES WINSLOW and Dr. Winn, who were appointed to examine the mental condition of the Rev. Mr. Rodwell, who was convicted for misdemeanour in shooting at the Master of the Rolls, have reported him to be quite sane.

THE death is announced of Dr. J. R. Mayer, of Heilbronn. The deceased was famous as the propounder of the mechanical theory of heat.

Correspondence.

SUPERSTITIOUS MATERIA MEDICA.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Seeing an article in your issue of the 6th of March, with the above heading, I think it may not be uninteresting to give a few "remedies" in common use among the poorer classes in the South of Ireland.

For Epilepsy.—Stuffing the mouth with salt.

For Thrush.—Blowing the breath of an orphan (if a bastard, so much the better) into the child's mouth.

For Coughs.—A tumbler of punch, with a lump of fresh butter in it. A decoction of gorse (in the South called Furze) blossoms.

For nettle-rash, produced by urtica ureas—Put a dock-leaf to the part stung, really useful, as I have often experienced.

To Increase Labour Pains.—Get the seventh son of a seventh son (rather a *rara avis* I should say), to give the woman three rolls in his arms.

To Check Uterine Hæmorrhage after Labour.—Tie all the limbs at short intervals with woollen threads. A rough idea of auto-infusion.

For Worms.—Large doses of saltpetre. A most mischievous remedy. I have seen violent gastritis set up by it more than once.

For Measles.—At first, hot-porter and sulphur, then new milk and sheeps' dung. Almost universal among the ignorant. Many a little life I have seen cut short by hot porter and sulphur within the last three months!

To Produce Vomiting.—Chewing tobacco, and swallowing the spittle.

For Warts.—"The fasting spit," *i.e.*, the first secretion of saliva after waking in the morning.

For Colic.—Application to the stomach of hot boards.

For Menorrhagia and Infantile Diarrhœa.—A decoction of blackberry bark. I have found this most useful in diarrhœa. Also mentioned by Dr. Churchill, in his work on diseases of children.

For Burns.—Strip off the raised cutical, and apply cabbage leaves. A most mischievous practice.

For Deficient Action of Kidneys.—A decoction of parsley. An excellent diuretic, as proved by personal experience.

For Sore Eyes.—Walking three times round a "holy well."

For Herpes Zoster.—Writing the patient's name over the spot. Dusting the vesicles with burnt wheat.

To Stop Bleeding from a Wound.—Cover the part with cow dung, A farmer's son once came to me with a wound in his cheek, and his face *masked* in cow dung; his very eyes full of it.

For Thecal Abscess, a very common complaint.—Bathe the part frequently in the patient's urine. Micturating over the affected fingers is a favourite method of "irrigation."

For Mammary Abscess.—Poultices of cabbage. The midwife will not allow her patient to sleep for two hours after delivery, for fear of flooding. The patient invariably gets a half-glass of whisky after the placenta comes away. She is made to sneeze with snuff, if the placenta does not come away immediately. The child is held up by the legs to open its stomach, and gets three turns from right to left. The reason for this I could never make out.

All the above "remedies" are so common that they have ceased to cause the slightest wonder, and are habitually practised in a district which contains three National Schools, which has a railway running through it, carrying the travellers in an hour and a half to Cork, and which was at one end to within two-hundred yards of the large town of Fermoy, and to within six miles of the town of Mallow at the other.

I am, Sir,

Your obedient servant,

THS. P. TUCKEY, M.B.

MEDICAL EVIDENCE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Please let me know if it is quite the etiquette of the medical profession for members of it, when properly feed, to attend assizes and be prepared to swear to matters—on behalf of the side from which the fee came—in a case they never saw either during life or after death, and said evidence to be diametrically opposite to that sworn to by another member, who not only attended the case while alive, but who made the *post-mortem* examination afterwards? I am, &c.,

IGNORAMUS.

[Any medical practitioner is fully entitled to attend and give evidence when requested as to matters of opinion either as regards diagnosis or treatment, although he may not have seen the case, and although his opinion, when given, may not be found to be applicable. If his opinion happens to be at variance with that of the medical attendant he will give it nevertheless, but it will probably carry little weight unless he has had personal knowledge of the circumstances. —ED. M. P. & C.]

EXPERIMENTAL PHYSIOLOGY IN THE UNIVERSITY OF DUBLIN.

A DECISION arrived at last week by the Board of Trinity College in reference to the question whether experiments upon the lower animals, for purposes of research, should be permitted in their Medical School, has given occasion for much astonishment and no little displeasure within the profession. Since the passing of the Anti-Vivisection Act, the University has made no application for a license for

a place to carry on experimental physiology, although other schools in Dublin have applied for and obtained such authorisation. Recently the application was made by the Professor of Institutes of Medicine, and on its being submitted to the Academic Council of the University, it was approved with all the reserve proper to the granting of such a permission. This resolution was, we understand, referred by the Provost and Senior Fellows, to whom it came for confirmation, to the Professors in the School, who by a majority of one decided *against* granting the authority to ask for a license, and this decision was endorsed last week by the Board, who have thus reversed the decision of the Academic Council, and refused permission for the pursuit of experimental research in physiology within the walls of the University. This determination has been received with much disappointment, and it has evoked a memorial which—in the following terms—is now in course of signature by the Doctors of Medicine and Masters of Surgery of the University.

Memorial to the Rev. the Provost and Senior Fellows of Trinity College, from Doctors in Medicine and Masters in Surgery of the University of Dublin.

We, the undersigned Doctors in Medicine and Masters in Surgery of the University of Dublin, beg most respectfully to petition the Board of Trinity College, to reconsider their decision of the 23rd March, 1878, as to the question of registering certain places within the precincts of the University, under the Act 39 and 40 Vic. chap. 77.

In support of our petition, we beg to state that—

1. By the decision in question, all original research in the domain of experimental physiology, pathology, and therapeutics is absolutely prohibited. No professor can legally make the simplest observation on any living vertebrate, if the conditions to which the animal is subjected can be supposed to give the slightest pain. Considering the very strict provisions of the Act, and that over and above these the Board would always have full power to make whatever regulations might be deemed advisable, we cannot but regard the decision as needlessly sweeping; and we are of opinion that it will not only debar the University from the performance of a most important duty, but that it will tend to cause clandestine experimentation.
2. While most willing to comply with the provisions of the Act, which require that no painful experiment shall under any circumstances be shown to a class, we are of opinion, that the demonstration of certain vital phenomena, such as can be shown only on the lower animals, is of paramount importance in the teaching of physiology; and physiology we consider to be the basis of medical education. Hence, as the decision of the Board puts a complete stop to all such teaching, we cannot but regard it as highly detrimental to the educational powers of the University. The effect most certainly will be, that students who are thus debarred from learning their profession scientifically in the University, must go elsewhere if they are to learn it scientifically at all.
3. We are of opinion that the decision will have the effect of deterring competent and efficient men from coming forward to fill the Professorships.

In the interests of the University, and of its reputation as a scientific institution of the highest rank, we greatly regret the course adopted by the board and the professors. Without going as far as the memorial does in saying that the students cannot learn their profession scientifically without vivisectional experiments, we feel that the University lost somewhat of its scientific character when its government gave expression to doubts as to the value of experimental physiology and as to the humanity of its own professors. We are sorry that occasion should be given to anyone to say that the University has failed to appreciate the services of experimental physiology to medicine and to science, and has mistrusted the disposition of its own teachers in their method of using the permission sought for.

If for no other reason, we regret the position taken by the board because it is, in a certain sense, a recognition and acknowledgment of the altogether false assertion of certain fanatics that vivisection is, under no circumstances, justified by its scientific results.

We can hardly experience much surprise that a conclave of severe elderly clergymen should take this view, but it is almost humilitaing to think that they have been prompted to it by a majority of the professors of the school, who would seem to have allowed themselves to become unacquainted with the usage of other schools in this respect, and to have been unaware of the progress of physiological science within recent years. We hope it may not be too late to repair the error committed. The board should be at liberty to hedge with any restriction they please, the permission which they are asked to grant, but they certainly ought not to refuse to their medical school the opportunities accorded to others, nor ought they to let the University of Dublin be placarded in company with those whose ignorance of physiological science allows them to declare vivisection unjustifiable.

Medical News.

University College Hospital.—The annual general meeting of the governors and subscribers to this charity was held on Saturday last, under the presidency of Mr. J. Chisholm Gooden. The report showed a total under all heads of 18,077 patients relieved against 15,810 in the previous twelve months. Of these 2,131 were treated in the hospital, the other 15,946 being out-patients, whose total attendances numbered 65,823. The total expenditure was £15,387, of which £2,057 was on account of the debts of the previous year; £3,100 had been added to the invested funds. After deducting the estimated annual cost of out-patients, &c., the total cost per bed in the hospital was £79 2s. 6d., the average per bed occupied was £92 8s. 2d. The balance at the end of the financial year was £1,175, and the outstanding debt was £3,555. The total receipts for the year, including legacies and balances from previous quarter, and a loan of £1,000 from the bankers, amounted to £18,158. The committee of the Hospital Sunday Fund had awarded £975, and £151 had been granted by the Hospital Saturday Committee. It was intended to make some alteration in the hospital, the estimate for which was about £4,000, to provide which amount the committee trusted their friends would assist them. On the motion of the Chairman, seconded by Sir George Young, the report was adopted. After a short discussion, in which the contemplated improvements in the hospital were fully ventilated, the question of private wards for paying patients being touched upon, the hospital committee for the ensuing year were appointed, and the meeting closed with the customary vote of thanks to the chairman.

NOTICES TO CORRESPONDENTS.

☞ Correspondents requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

READING CASES.—Cloth board cases, gilt-lettered, containing 26 strings for holding each volume of the MEDICAL PRESS AND CIRCULAR can now be had at either office of this Journal, price 2s. 6d. The postal regulations not allowing the Journal to be stitched, these cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

NOTICE TO SUBSCRIBERS.—Subscribers who have not already paid their subscriptions for last year are reminded that they are now due, and should be sent to the publishers, who will be happy to acknowledge their receipt.

DR. MORGAN WILLIAMS, Cardiff, is thanked.

DR. BERNE, Madras.—Communication received, and will be considered. The preparation about which you inquire is a decided improvement upon anything hitherto in the market. The profession are using it largely in this country.

MR. DICKINSON, Pailton, Rugby, will please receive our best thanks for his encouraging note.

A CANDIDATE FOR THE SERVICE.—Matters look a little more reassuring now than a week ago, and it is probable "the rush" will not take place.

A SUFFERER FROM QUACKS should have consulted his family medical attendant at first and kept out of the hands of the notorious Hunter and others. We never prescribe in our columns. We are sorry he has spent all his money upon quacks, but that is not a reason why he should be "doctored" by respectable men for nothing.

HOLLOWAY'S PILLS.—At the recent trial of the case of alleged poisoning in Galway, the following occurred in the examination of Professor Cameron by the Attorney-General: Prof. Cameron—I analysed Holloway's pills that were sent me; the deceased was not poisoned by the pills. I think the pills consist of aloes and some coloured matter—it might be *gamboge*. Seven of Holloway's pills would not injure him, 200 would not do him much harm.

DR. E. P.—We cannot undertake to advise you as to a London practitioner to be consulted in the speciality to which you refer.

THE MEDICAL SOCIETY OF THE COLLEGE OF PHYSICIANS, IRELAND.—This evening, at 8 o'clock, the following communications are set down for reading: Dr. Williams, "The Treatment of Pleurisy and Empyema." Dr. Harvey, on "So-called Compensatory Emphysema in Acute Thoracic Diseases." Patients presenting interesting forms of disease will also be exhibited by some of the members.

HARVEIAN SOCIETY.—Thursday, 8 p.m., Mr. Hy. Morris's "Report on Diseased Kidney." Dr. Griffith, "Case of Congenital Displacement of Heart." Mr. Teevan, "The Importance and Means of Effecting an Early Diagnosis of Stone in the Bladder."

DR. BUCKNILL will deliver the Lumleian Course of Lectures at the Royal College of Physicians of London on April 5, 10, and 12, at 5 p.m. each day. The subject chosen is "Insanity in its Legal Relations." Members of the profession will be admitted on presentation of card.

DR. CROFT.—The post-card you received is but one specimen of many we may expect if the obnoxious "Dental Reform Bill" becomes law. "To what depths," &c.; quotation very *apropos* just now.

AN Evening Meeting of the Pharmaceutical Society of Great Britain will be held on Wednesday, April 3rd, 1878, at 8 o'clock.

OBSTETRICAL SOCIETY OF LONDON.—Wednesday, April 3rd, at 8 p.m., Specimens: A Fœtus whose Head was Ruptured by means of the Forceps, by Dr. Cory; Cancerous Polypi removed during Pregnancy with microscopical sections, by Dr. Galabin. Papers: Mr. Lawson Tait, "Two Cases of Repair of the Female Bladder and Urethra." Dr. Hicks and Dr. Skinner, "Cases of Rupture of the Uterus."

PROF. GALEZOWSKI'S paper "On Hysterical Contraction of the Muscle" shall appear in an early number.

DR. HAMILTON'S "Method of Removing Tumours," Dr. Atkin's "Othœmatoma," and Mr. Swan "On Spinal Curvature" papers received.

COMMUNICATIONS, Enclosures, &c., have been received from—Dr. Andrew Clark, London. Dr. Beaney, Melbourne. Mr. William Adams, London. Mr. Erichsen, London. Dr. Ferrier, London. Dr. de Fourmartin, Chelsea. Dr. Adams, Ashburton. Dr. Tuckey, Castletownroche. Mr. Marlett Boddy, Camberwell. Mr. G. P. Field, London. Mr. Burdett, Greenwich. Mr. G. Jesse, Henbury. Mr. Campbell, London. Dr. Greene, Peckham. Mr. Hay, Hull. Dr. Ogden, Toronto. Dr. Powell, London. Dr. Balthazar Foster, Birmingham. Dr. Gowlland, London. Mrs. Waring-Curran, Mansfield. Dr. Braithwaite, Leeds. Dr. Dolan, Halifax. Mr. Jabez Hogg, London. Dr. Gouzaley, Madrid. Mr. Jupp, Brompton. Mr. Lawson Tait, Birmingham. "A Member of the British Medical Association." Dr. John Drysdale, Liverpool. Mr. Seymour Haden, London. Mr. Lennox Browne, London. Mr. Holmes, Dublin. Dr. Ledwich, Dublin. Dr. Hamilton, Edinburgh. Dr. Smith, Manchester. Dr. Williams, London. Dr. Peirson, Scarborough. Dr. Jagielski, London. Dr. Edmunds, London. Dr. Stretch-Dowse, Hornsey. Dr. Richardson, Dublin. Dr. McGrigor Croft, St. John's Wood. Mr. Notter, Netley. Dr. Maclaghan, Dundee. Mr. Tufnell, Dublin. Mr. Watson, London. Mr. Nugent, Liverpool. Dr. John Williams, London. Dr. Meymott Tidy, London. Dr. Howard, New York. Mr. R. Skinner, Winchelsea. The Secretary, Royal Humane Society. Mr. Lepage, Calcutta. Dr. Bayes, London. Dr Rees Powell, Cwmpadest, Brecon. Dr. Barnard, Buxton. Dr. Milner Fothergill, London. Dr. W. Johnston, Leicester. Mr. Horsman, London. Dr. Herbert Major, West Riding Asylum, Wakefield. Dr. Walbaum, German Hospital, Dalston. Dr. Morgan Williams, Cardiff. Dr. Wolfenden, Tutbury. His Grace the Duke of Westminster. Mr. Hyslop, Church Stretton. Mr. G. M. Dickinson, Pailton, Rugby. Dr. Thornley, Newry. Dr. J. Kent Spender, Bath, &c., &c.

VACANCIES.

Athy Union, Athy Dispensary.—Medical Officer. Salary, £130. Election, the 9th inst.

Birmingham Queen's Hospital.—Physician. Honorary. Applications, with testimonials, to be forwarded on or before the 13th inst.

Bootle Borough Hospital.—House Surgeon. Salary, £80, with board. Applications to the Hon. Sec. before the 10th inst.

Bristol General Hospital.—Physician's Assistant. Salary, £50, with board and lodging. Election, April 25. Applications to the Secretary.

East London Hospital for Children.—Resident Medical Officer. Salary, £60 per annum, with board, &c. Applications to the Secretary on or before April 11th at the Hospital, Shadwell, E. (See Advt.)

Ennis District Lunatic Asylum.—Resident Pupil. Salary, £50, with apartments and rations.

German Hospital, Dalston.—Assistant Surgeon. Honorary. Candidates must be German, or thoroughly conversant with the German language. Applications, with diplomas, to the Hon. Sec., on or before May 1. (See Advt.)

Leeds Public Dispensary.—Junior Resident Medical Officer. Salary, £80, with board. Apply before the 10th inst. to Dr. Churton, Leeds.

Royal Cornwall Dispensary.—House Surgeon and Secretary. Salary, £200, with furnished apartments. Applications to the Hon. Treasurer at the Hospital, Truro, before the 24th inst.

Roscommon Infirmary.—Apothecary and Registrar. Salary, £60, with apartments, rations, &c. Election, the 19th inst.

St. Thomas's Hospital.—Ophthalmic Surgeon. Honorary. Full information of the Secretary. Election, the 17th inst.

Warneford Hospital.—House Surgeon. Salary, £100, with board. Applications, with testimonials, to the Secretary at the Hospital, Leamington.

APPOINTMENTS.

GOULD, A. P., F.R.C.S.E., an Assistant Surgeon to the Westminster Hospital.

HOLLAND, L., M.B., M.D., Aural Surgeon to the Newcastle Dispensary.

KYENE, J., F.R.C.S.E., Aural Surgeon to the Westminster Hospital.

LUSH, J. S., M.R.C.S.E., Medical Officer for the Seventh District of the Devizes Union.

PERCIVAL, G. B., M.B., M.R.C.S.E., a Surgeon to the Northampton General Infirmary.

ROE, St. George J., L.R.C.P., L.R.C.S.Ed., Medical Attendant to the Royal Irish Constabulary, Coolany and Templehouse, co. Sligo.

Marriage.

DE MONTMORENCY—KEMMIS.—March 28, at Booterstown, co. Dublin, the Hon. Arthur Hill Trevor de Montmorency, M.D., L.R.C.S.I., to Caroline, youngest daughter of the Rev. George Kemmis, of St. Helen's, Blackrock.

Deaths.

BROWN.—On March 22, at Milford Hants, Dr. Robert Brown, late of the Bombay Army, aged 75.

DICK.—On March 24, at West Claremont Street, Edinburgh, Robert Dick, M.D.

GANE.—On March 19, at Clifton, James Gane, M.R.C.S.E., aged 74.

KITCHING.—On March 25, at Heworth, near York, John Kitching, M.D., aged 65.

MARA.—On March 23, at Athy, co. Kildare, William Francis Mara, L.R.C.S.I., L.K.Q.C.P.I.

MORRISS.—On March 17, at Trieste, Samuel Morriss, L.R.C.S.I., Resident Medical Officer of the Borough Gaol, Liverpool.

PITMAN.—On March 22, at Acacia House, Highgate, Robert Pitman, L.R.C.P., &c.

ROBERTS.—On March 23, at Cimiez, Nice, John Roberts, M.R.C.P.L., late of Upper Norwood, aged 65.

THOMSON.—On March 22, at Partick, Glasgow, Wm. Cooper Thomson M.D.

TOOTELL.—On March 24, at Mitree, Scinde, Edward Tootell, L.R.C.P., Surgeon, 30th Regiment of Native Infantry, aged 28.

THE CAUSES AND COURSE OF DISEASES OF THE HEART, WITH SPECIAL REFERENCE TO PREVENTION AND TREATMENT. (a)

A Course of Lectures delivered at the West London Hospital.

By J. MILNER FOTHERGILL, M.D., M.R.C.P.,

Assistant Physician to the Hospital, and to the City of London Hospital for Diseases of the Chest, Victoria Park.

Lecture II.—Hypertrophy and Dilatation.

The lecturer commenced by saying that it was commonly stated in text books that hypertrophy was to overcome obstruction, thus endowing the tissues of the heart with a species of intelligence. Certainly, obstruction to the onward flow of the blood is a common cause of cardiac hypertrophy, but by no means the only one. Whenever the pressure within the cardiac cavities is increased, and the heart walls are unwontedly distended, then changes are set up which will ensue in pure hypertrophy; in a blended condition of hypertrophy with dilatation, or in simple dilatation, according to (1) the amount of distending force; (2) the time allowed for muscular compensation; and (3) the nutritive powers of the individual. If the conditions permit of pure hypertrophy, a perfect compensation may be attained, which may last for many years, the patient not being conscious of anything being amiss with him. If, on the other hand, simple uncomplicated dilatation be the consequence, then the patient's powers are much crippled, and he, or she is to all intents and purposes an invalid.

The causes of obstruction to the onward flow of the blood leading to hypertrophy are aortic stenosis, the high blood pressure of chronic renal disease, and thoracic deformity distorting the aorta. When such obstruction is offered to the onward flow of the blood on the ventricular systole, the ventricle is incompletely emptied, and a certain amount of blood is already present in the chamber when the blood rushes in from the gorged pulmonic veins. The blood rushes in until the pressure within the veins and the ventricle is equal, the contraction of the auricle increasing the pressure within the ventricular chamber, and thus great distension of it results. This over-distension is the first step in the production of hypertrophy or dilatation; for they are not separate processes, but parts of one process. Over-distension is produced, too, in aortic regurgitation, where the ventricle is distended by the new current coming in through the imperfect aortic valves, as well as the normal current. Here there is usually massive hypertrophy, and yet the obstruction offered by the shrivelled valves is small. But the force of the incoming current, driven backwards by the powerful aortic recoil, is great. If it were not for this massive muscular growth, the left ventricle would soon be over distended to the point of paralysis by the incoming current. When the muscular walls become fattily degenerate, the dilating process goes on again, and death from paralysis of the chamber in diastole is common in the later stages of aortic regurgitation. This massive hypertrophy in aortic regurgitation has been spoken of by some writers as "over-compensatory;" and certainly it is over-compensatory to any obstruction to the blood flow which exists, but not over-compensatory to the force of the current flowing into the ventricle backwards through the incompetent aortic valves. Certainly this enlarged and powerful ventricle ruins the arteries from the distension to which it subjects them on its systole. Here again, too, we find, as Niemeyer points out, that in mitral regurgitation there is also often found a condition of hypertrophy of the left ventricle. Here, surely, there is no obstruction to be overcome, for there is an unchanged aortic orifice with a second orifice in the leaking mitral valve. But again we find an increase in the internal pressure during diastole, for the blood in the pulmonic veins is driven onwards by an enlarged right ventricle, and this current is met by the backward current through the insufficient mitral valve, so that the pulmonic veins are gorged. The blood rushes into the ventricle till the pres-

(a) Abstract of Lecture II. delivered March 27th, 1878.

sure within it and the veins are equal, and so over-distension of the left ventricle is produced in mitral regurgitation. In mitral stenosis, where the impact of the current from the gorged veins is broken by the narrowed ostium, the left ventricle is not so over-distended, and no change is set up, unless it be that at times the left ventricle is somewhat diminished in size. Increased internal pressure in diastole is then the exciting cause of hypertrophy and dilatation.

In order to comprehend this properly the lecturer said it was necessary to remember that the cavities of the heart are not of fixed and unalterable size. If a thin man be taken, and a finger placed on his apex beat, and he be told to hold his breath, the apex beat is soon lost, as the right ventricle becomes distended with blood. When the breathing is resumed the apex beat soon becomes again distinct. We know, too, that jugular pulsation is produced by over-distension of the right ventricle until the tricuspid valve flaps become insufficient, as a temporary condition. The same thing occurs in the left ventricle, and a mitral systolic murmur is heard along with a dilated left ventricle, and is lost when the ventricle recovers its normal size. Dr. George Balfour denominates this condition, "Curable Mitral Regurgitation." Dr. Broadbent has at St. Mary's Hospital an out-patient with aortic regurgitation, in which there is now secondary mitral regurgitation. The lad was confined to bed with an illness, and on getting up again the ventricle was found reduced in size, and the mitral murmur gone. On resuming exertion, the ventricle again enlarged, and the mitral murmur returned. These passing changes in the cavities of the heart may become more permanent as dilatation; and the same means by which temporary conditions are recovered from, are those by which the more permanent conditions are remedied. Claude Bernard held that the cardiac ventricles were, to some extent, reservoirs of blood at times.

As to how increased internal pressure leads to hypertrophy, we know that the more functionally active muscular fibre is the more blood it attracts to itself, and persons can voluntarily add to their muscular power by exercising their muscles. Also, too, we know that when a motor nerve is irritated, not only is its associated muscle set in action, but the blood-vessels belonging thereto are dilated; and this dilatation of the vessels is produced even when the muscle is paralysed by curara. We know too that when blood is experimentally driven into the heart with unwonted force, more rapid and more powerful muscular contractions follow. The sense of distension of the heart walls is transmitted by the sensory nerve of the heart to the cardiac ganglia, and more energetic nerve discharges lead to more powerful muscular contractions. Section of the vagi does not affect this. The more energetic muscular action is accompanied by dilatation of the blood-vessels and a more liberal supply of nutriment, and so hypertrophy of the muscular structure is brought about.

But for the development of hypertrophy it is necessary that the change necessitated be not too sudden; if too rapid, there is not time for the compensatory muscular growth to take place, and dilatation is unavoidable. It is also essential that the nutritive powers of the individual be good, else the growth is imperfect. Thus in women conditions of high blood pressure in the arteries in chronic renal disease, are commonly productive of dilatation, with more or less hypertrophy, where pure hypertrophy is the rule in men. Sex then influences the result. Position in life, the capacity to procure a sufficiency of food, and to avoid toil, affects the result; as does also the opposite condition of poverty. Rest in bed for a time will often enable a crippled heart to go on fairly well for some time.

From this review of the causal associations of hypertrophy, we can see how we may help the efforts of the organism to set up hypertrophy when not quite able to achieve it unassisted. We can enforce rest, furnish food suitable in quality and quantity, and improve the blood by iron. At the same time we can increase the energy of the ventricular contractions by acting on the cardiac ganglia by digitalis, strychnia, or belladonna. By such means we may in many instances build up hypertrophy around a dilated ventricle, even when we cannot succeed in reducing the enlarged chamber to its normal size.

The lecturer then referred to the progress of hypertrophy, and pointed out that when it was associated with aortic regurgitation it was not usually durable, because the blood, no longer caught by the aortic cusps on the aortic recoil, did not continue to fill the coronary vessels. When the coronary vessels were well filled the case might go on for a great number of years. When the structure of the heart is undermined by fatty degeneration, the walls yield, dilatation is unarrested, and the case is apt to end suddenly from over-distension of the decayed walls and arrest of the heart in diastole. Physical signs alone could not distinguish betwixt a heart once hypertrophied commencing to undergo the dilating process from decay of its walls, and a heart, where hypertrophy blended with dilatation had existed for a long time; here disease of the heart is not a matter to be settled by the stethoscope. The diagnosis here turns on the concomitant general condition.

As to the question, Is hypertrophy ever harmful? It must be admitted that it carries with it certain consequences of its own. By maintaining the high blood-pressure in the arteries in chronic Bright's disease, it leads to atheroma of them; while in aortic regurgitation, the large and massive ventricle ruins the arteries by suddenly throwing an abnormal amount of blood into them with unwonted force. The hypertrophy which was of use to resist the new and potent distending force, in its turn was ruinous to the arteries.

As to the treatment of hypertrophy, the lecturer said, the great point was to conserve it as long as possible. Certainly nothing should be done to attempt to reduce it, except by doing away with the exciting cause, as where it is associated with gout. The great dangers were the reduction of the powers till the hypertrophy became blended with dilatation; and the ultimate fatty degeneration of the muscular fibrillæ. In hypertrophy of the heart, small doses of digitalis only were permissible, and large doses were fraught with danger. While, in simple dilatation, it was questionable if a patient could be poisoned by medicinal doses of digitalis. Where there was good hypertrophy, the patient might take a fair amount of exercise, or work for a living; but with dilatation, the powers were greatly crippled, and rest and good nutrition, with the exhibition of appropriate medicinal agents, were doubly necessary. By judicious treatment, many dilated hearts might be reduced in size; and even where reduction to the normal size was unattainable, it was possible to surround the dilated chamber with an hypertrophied wall. In all cases the aim of the medical man should be to aid the natural efforts to attain hypertrophy and to avoid dilatation.

ON DERANGEMENT OF VISION IN HYSTERICAL PATIENTS.

(*A Lecture delivered in the Salpêtrière Hospital, Paris, by* Professor CHARCOT).

Translated by ARCHIBALD H. JACOB, M.D., F.R.C.S.,
Formerly Ophthalmic and Aural Surgeon to the City of Dublin Hospital, and the Dublin Eye and Ear Infirmary.

(*Continued from page* 253.)

THE following is a combination most interesting from a clinical point of view, and which has been met with several times by M. Charcot:—

The patient suffers only on one side, the right, for example, from slight analgesia of the trunk and limbs, while in the face, at the same side, there is complete and

well-marked anæsthesia. At the same time achromatopia is absolute in both eyes, or at most, the patient perceives with the left eye, and that only by moments, the peripheric colours—viz., blue and yellow.

This combination has shown itself among others in a very clear manner, in the case of a young woman, an hysterical patient, sent to M. Charcot by Dr. Fieuzal, and whom he has introduced during his lectures on colours. In those cases, the contraction, to a certain extent normal of its kind, of the field of vision in the comparatively healthy eye, has been exaggerated to such a degree (and it is in this that the anomaly consists) as to be almost equal to the contraction which takes place in the eye primitively and principally affected. This anomaly points out, if one can thus express oneself, the *high road* to the interpretation of certain cases of hysterical amaurosis, in which the existence of hemi-anæsthesia, and of several other permanent and fundamental symptoms of diathesis, are either wanting, or are very slightly indicated.

However remarkable they may be, it should be clearly understood that, setting aside the frequent mobility of symptoms and the almost necessary coincidence of the other phenomena peculiar to the diathesis, these symptoms of hysterical amblyopia do not properly belong to hysteria. This is the point upon which M. Charcot has long insisted. He has shown (*a*) that all of them are found in various shades of development in monocular amblyopia, accompanied by sensorial and sensitive hemi-anæsthesia arising from lesions in the commissure of the brain, which occur in the posterior parts of the internal capsule at that point which he has designated in his lectures under the name of *carrefour sensitif* (*b*)—the same diminution of acuteness of vision, the same concentric and general contraction of the field of vision for colours, marked in both eyes, but predominating to a high degree in the eye corresponding to that side opposite to that which is the seat of intra-encephalic lesion, the same absence in the body of the eye of lesions appreciable to the ophthalmoscope.

The various characteristics of this species of amblyopia belong, then, as may easily be seen, to cerebral hemi-anæsthesia in general, and not to hysterical hemi-anæsthesia in particular. The interest afforded by this relation can be easily understood, not only from a practical point of view, but also from a theoretical point of view. For example, the position occupied by the organic lesions of the commissure capable of determining the production of total hemi-anæsthesia—sensorial and sensitive—of cerebral cause appears to point out naturally the position of the lesions which are inappreciable to our actual methods of investigation, *dynamical*, as they are sometimes called, which control the corresponding hemi-anæsthesia of hysterical patients.

These latter lesions, therefore, are probably seated either in the fibres which traverse the sensitive ganglia, or in their prolongation on the surface of the brain, or in all these positions.

M. Charcot has, in the same lecture, pointed out another species of derangement of vision, long since remarked by him, and considered by him as being very frequently met with in hysterical patients, and which, to his knowledge at least, has not yet been described.

It is known that various and strongly-marked hallucinations of vision are, so to speak, normal accompaniments of the delirium of hysterical patients. Now, hallucinations of this kind exhibit themselves very frequently in patients in the intervals between the convulsive attacks, in their track, or even at the time when the patient is menaced by them..

It is very common to see hysterical patients, in their periods of calm, seated tranquilly at needlework, get up, leave their seat, uttering a cry as if they had been surprised by the sight of some terrible object with which they wish to avoid all contact. If they are interrogated as to the motive of these unexpected movements, they declare that they believe they saw animals, particularly rats, sometimes cats, and at other times fantastic beasts, running on the floor, or on the neighbouring wall; more rarely, it is the appearance of grimacing heads which causes this terror. One learns further that imaginary animals, generally grey or black in colour, sometimes, but more rarely brilliant red, are perceived by each patient always on the same side; and the side on which the hallucination takes place is always that which corresponds to the hemi-anæsthesia, and consequently to the amblyopia.

Thus, if hemi-anesthesia occur on the right side, it is always at the right of the patient that the imaginary animals appear; while if hemi-anesthesia occur on the left, they appear at the left.

The animals pass usually in a line, and run rapidly, coming from behind the patient and moving forward. They generally disappear when the patient turns her eyes directly towards the side on which they appear. However, it may happen that the hallucination persists much longer in all its vigour when the patient is on the verge of a sharp nervous attack, in the middle of the attack, or recovering from a fit.

M. Charcot has shown to his audience, and interrogated before them ,a certain number of women in whom is exhibited habitually, and in a very clearly-marked manner, this species of derangement of vision.

1. M.—Hemi-anesthesia of the left side. Dischromatopia of the left eye. Often sees grey and black rats running to her right on the floor, or on her bedclothes.

2. W.—Total anæsthesia, but predominating on the left side; achromatopia of the left eye; double predominant uvairitis at left side. Coming out of these attacks she is often tormented by the vision of lions, whose figures stand out in brilliant red on the white wall of the room in which she is lying. These animals always appear to the left-hand side of the patient; they pass rapidly, and disappear when she looks at them full in the face.

3. V.—Sees, in the intervals between the attacks, but above all, when one is on the point of seizing her, sometimes a black cat, sometimes a white phantom appearing to her left. The patient suffers from total anæsthesia and double uvairitis, but these phenomena predominate on the left. Dischromatopia of the left eye.

4. B.—Even when this patient is in a state of calm she is often frightened by the sudden and unexpected arrival of a large grey cat at her right side, which appears to jump upon her suddenly, and which she even believes she feels the touch. This patient suffers from hemianesthesia on the right side.

5. G.—Suffers from hemi-anesthesia and achromatopia at the right side. Often sees to her right cats and black rats running on the floor, which seem to come from behind her.

6. A.—Lost her sight almost entirely in infancy, in consequence of disease of the centres of the eyes. When threatened by an attack she imagines she sees red men appearing suddenly to her right. This patient suffers from hemi-anæsthesia, and uvairitis on the right side.

Numbers of such examples might easily be given. These are the principal derangements of vision which are usually met with in epileptic hysteria—hysteria major; and also frequently in common hysteria—hysteria minor. Many other derangements of vision may also be observed under the same circumstances; but are much more rare, such as faults of accommodation, certain forms of diplopia, &c. Such have been observed in the case of a patient sent by M. Galezowski; and the latter has, at the request of M. Charcot, entered into a description of them, the substance of which I hope to give at another time.

ON THE VICIOUS SYSTEM OF DRAINAGE PREVALENT IN WEST-END HOUSES. (a)

By Dr. FITZPATRICK.

Introductory.

I should like to begin by making a slight alteration in the title of my paper. When first communicated to our Society it stood thus—"On the Defective State of the Drainage in West-End Houses, with Cases of Zymotic Disease arising therefrom," and it is so printed in the medical journals. On consideration I would prefer to style it—"On the Vicious System of Drainage Prevalent in West-End Houses, &c.," because the idea I wish to express is not that the drainage in such houses is a minus quantity, or less in extent than it ought to be, but that it is designed on an entirely erroneous system. It affords ample facilities for the deportation of refuse matter, but exposes the inmates of the houses to a reflux of unhealthy gas. This is really the point of my paper, and, in order to illustrate it satisfactorily, it will be necessary to make a few prefatory remarks on house drainage in general. I hope it will be no disparagement to the knowledge of my professional brethren to assume that this subject does not ordinarily much occupy their attention. In point of fact, theory and practice in this department have advanced so rapidly within a short period that few of those engaged in it would submit to be judged by the work done or opinions advanced only two or three years ago, and it is because circumstances have made me familiar with its latest and most approved developments that I have been encouraged to bring the subject under your notice.

We know it is not taught as a branch of medical education. I do not remember having ever seen it adverted to amongst the multifarous subjects that form the staple of our introductory lectures, and I had occasion to remark that all mention of it was omitted from a late Presidential address delivered before this Society, in which the outgoing President specially occupied himself in delineating the acquirements of the ideal physician of the future.

Nevertheless, Sir, I think it can hardly been contested that for medical men engaged in the daily practice of their profession some acquaintance with the question of drains and drainage would be of great utility. *Rerum cognoscere causas* is an acknowledged part of the *rôle* demanded by public opinion of modern professors of our art. It will no longer suffice to inform a patient or his friends that he is the subject of typhoid fever, for simultaneously the question will arise how and where the disease has been acquired. It is an accepted and well-attested theory that sewer gas, or certain organisms resident in it, is a factor in the production of a whole class of diseases, and therefore, I submit, it is convenient, perhaps important, to some of us to know the conditions under which so deleterious an agent is likely to produce its effects. What is the nature of sewer gas? Where is it generated? By what channels does it obtain access to the interior of a house? By what means is its presence to be prevented or counteracted? These are a few of the questions that meet us on the threshold of this inquiry.

It will not be necessary here to enter into an examination of the numerous chemical constituents of sewer gas. It is enough to know that it is a product of decomposing excrementitious matters; that it is extremely light and volatile, and readily affected in its diffusive powers by variations of atmospheric pressure. Some other of its physical qualities I shall have occasion to point out as we go on. It is generated wherever there are decomposing excrementitious substances, and most freely from an admixture of solid and liquid sewage. Practically, as regards London houses, its principal source is the main sewer in the roadway, and, owing to the difference of atmospheric pressure, which is always less in the interior of houses than in the sewers, particularly in summer, and from the acquired warmth of the apartments, there is generally a current from the sewer into the house.

(a) Paper read at the Harveian Society.

Next, by what channels does this noxious agent obtain entrance into our dwellings? This is the most important question of all, and, as an eminent member of our own body expresses it, "is still very imperfectly understood by the public, by the majority, I fear, of builders, and by not a few house surveyors and engineers"—I would add, also, by some of our leading architects. To make this matter plain, it will be as well now to ask your attention to these drawings, and we shall take the water-closet as the starting-point of our descriptions. When excrementitious matter of any kind is deposited in the pan of the w.c., and the valve withdrawn, it is carried by the agency of the water into the soil-pipe. This is the vertical lead pipe, usually four inches in diameter, figured here descending to the house drain. In most London houses the water-closets are built at the back, so that, in order to reach the main sewer in the roadway, it is necessary to construct a drain which passes from rear to front under the basement. By this channel the contents just discharged from the water-closet are carried to the main sewer in the street. Now it is evident that the gas accumulated in the main sewer and subjected to atmospheric pressure, will readily find a way back through the house drain to the soil pipe, where we will assume it is temporarily arrested by the valve of the water-closet. Remove the valve, displace the column of water resting upon it, and immediately a door is thrown open for the entrance of sewer gas. II. But that is only one mode in which it finds admission to the house. Let us now examine a second. We all know that in London houses water is stored in cisterns. It is admitted to the cistern through an open pipe, which closes as the cistern becomes full, by the automatic action of a ball-cock. But if, through any hitch, this ball-cock ceased to act, the water would continue to flow uninterruptedly, and the house be flooded. To guard against so disagreeable and injurious an accident, every cistern is furnished with an overflow-pipe or waste, the open trumpet-shaped extremity of which stands a little above the surface of the water when the cistern is full, and the incoming water has ceased to run. Where does this pipe, ordinarily 2″ in diameter, terminate? Either in the drain or in the soil pipe; so, you see, here, again, is another channel for the admission of foul air, whence it is not only diffused into the atmosphere of the house, but becomes absorbed by the water in the cistern. Thirdly, there are the sinks (as you see here) situated in various parts of the house. There is usually one in the scullery, one in the pantry, one on each floor for the housemaid, and the gentleman of the house has probably one arranged as a lavatory in a corner of the w.c. on the ground floor. The wastes from those sinks run into the drain, or into what is equally bad—the trap of the water-closet, and thus afford, as you can readily see, another avenue for the entrance of sewer air. Nor is this all, for there exists yet another source of danger in the rain-water pipes. You see these descend from a balcony, it may be, or a flat, from the floor of a conservatory, or elsewhere, and run uninterruptedly into the drain. Thence, of course, the sewer gas is free to ascend and enter the open windows, or mingle its pestilential breath with the fragrant odours of the flowers in the conservatory. Thus there are five channels, as I have pointed out, by which this poisonous gas makes its way from the main sewer into the house: 1. The soil pipe; 2. The overflow pipes or "wastes" from the cisterns; 3. The "wastes" from sinks and baths; 4. The rain-water pipes; and, 5. The house drain itself if it should be anywhere imperfect. I shall have to advert to yet another source of contagion, independently of the sewers, but that will be more conveniently explained further on. Now, for the sake of simplicity, I have omitted in this brief sketch all mention of "traps," whose varieties are legion, but which have for a common object the exclusion of sewer air from the house. The principle on which they are all constructed is that of interposing a stratum of water between the house on one side, and the sewer gas on the other. One of the simplest is that which is usually introduced into the overflow pipe of the cistern—so simple, indeed, as, in practice, to be utterly fallacious.

A bend is made at one point of the pipe, so that, as it runs, some water is deposited there; but, practically, the ball-cock apparatus of the cistern always acts, and the overflow pipe is rarely, if ever, traversed by water. The consequence is, that whatever water was originally left in the bend very quickly evaporates, and the way is again perfectly open for the passage of the sewer gas. Another contrivance, similar in principle, is the ordinary D trap. This trap is a sort of fetish amongst builders, and, in their system of defence against sewer gas, they invariably assign to it the post of honour at the bottom of the water-closet. In that situation it is an unmitigated nuisance. It does not serve the purpose for which it is employed, and, by retaining a portion of the soil passing through it, it tends to become very foul, and forms itself a small cesspool. On no account is a D trap to be tolerated in a water-closet.

Let us now assume, for a moment that this D trap may itself, in the course of a year or two, become foul and coated with excrementitious matter. It will then form a further source for the discharge of sewer gas, either directly through the water closet, or indirectly in the following way: underneath the seat of every water-closet is what plumbers call a safe; it is a flat leaden tray, surrounded by a high flange, resting on the floor, and designed to catch any accidental overflow, such as slops, escaping between the pan and seat of the water-closet. It is, of course, provided with a waste to carry off its contents. and this waste is made to terminate in the trap. You see, therefore, there is an open pipe communicating between this independent focus of sewer gas and the air of the apartment.

Lastly, how are these evils to be prevented? Only in one way, which is almost self-evident from the statements I have made of the several modes in which contamination occurs. Every pipe leading from cistern, bath, and sink, and every rain-water pipe, must be "disconnected"—that is, instead of terminating in the soil pipe, or the D trap, or the drain itself, it must discharge its contents in the open air. You need not have a better illustration of the principle than this, where the set of pipes represented here are carried outside the house over an open water head (as here). Similarly, the "wastes" on the ground floor discharge in the area over gully traps; the rain-water pipes do the same.

DISCONNECTION

Can be applied without difficulty or hesitation to those pipes that carry only the waste water from baths, sinks, and cisterns, or the rain-water from roofs and balconies. In the case of the soil pipe there seems, antecedently, an insuperable objection to applying the same principle, for it is evident you cannot allow soil to be discharged in the area over the opening of a trap. But by more than one simple modification the disconnection can be virtually effected. The object of all disconnection is to admit atmospheric air to the pipes instead of sewer gas. Builders had an inkling of this, and attempted to effect it by what they call ventilating the soil pipe. This was done by inserting in the angle of the soil pipe, where it forms a bend to reach the topmost w.c., a smaller pipe, which was carried above the highest windows and surmounted by a cowl. It was thought that this pipe favoured the escape of the sewer gas pent up in the soil pipe, and so relieved its pressure upon the water-closets, and diminished the danger of its passing by those channels into the house. I am not prepared to deny that it may have some such effect, and, at any rate, I admit that this additional pipe, intended to act as a funnel to the sewer gas in the soil pipe, is a step in the right direction. But, as a whole, the arrangement is quite inadequate to the purpose intended. In the first place, the soil pipe ought to be carried above the highest windows *in its integrity* and not merely tapped by a smaller pipe of half the diameter inserted into it. And more than that, it is essential that air be admitted to the soil pipe from below, so that it be traversed by a perpetual current. The latter may be done in two ways—either as you see here, by a vertical shaft extending from the area into the drain; or as in this drawing, where the drain is virtually disconnected, and discharges its contents along this sunk channel into the syphon trap.

(To be continued.)

ON THE VALUE OF KOUMISS IN THE TREATMENT OF NAUSEA, VOMITING, AND INABILITY TO RETAIN OTHER FOOD IN THE STOMACH (*a*)

By N. JAGIELSKI, M.D., M.R.C.P.L.,
Physician-in-Ordinary to the Infirmary for Consumption, Diseases of the Chest, &c.

THE author selected ten remarkable cases on this subject that had come under his own observation, five cases successfully treated with koumiss by other medical practitioners, whose names are given below.

The first case described by Dr. Jagielski was a patient of Mr. Wallis Mason and Mr. B. Floyer, a very anæmic lady, who was confined with twins at full term. General paralysis followed, her prostration had become extreme in six days after the confinement in consequence of her inability to retain any food on her stomach; and when seemingly dying the koumiss was given to her in small quantities at frequent intervals. All nausea and vomiting disappeared during the exclusive treatment with koumiss, which proved, besides to nourish the patient alone sufficiently, to increase her strength and bodily weight in a very short time. The three medical attendants were firmly convinced that in this case life was saved by the koumiss.

2. A case of pregnancy with hæmoptysis, subsequent vomiting, and inability to retain anything on the stomach, in which the treatment with koumiss allayed the vomiting speedily, and enabled the patient to come safely over her confinement, her health remaining very good afterwards.

3. Acute attack of chronic bronchitis, with excavations in both lungs, &c., in a gentleman 78 years old, whose hapless condition on the sixth day of his severe illness caused Dr. Jagielski to give him the sparkling koumiss, under the influence of which the constant vomiting was readily overcome, and the rapidly declining strength renewed. His excessive expectoration diminished, his sleep returned, and his relative health was soon restored.

4. A case of most obstinate gastric catarrh, with all the appearance of a carcinoma pylori, complicated by very distressing vomiting and consecutive exhaustion, which resisted all drug treatment, and all varieties of dietetic food, soon yielding to the exclusive use of koumiss.

5. A case of uninterrupted hæmoptysis during nine weeks, with vomiting and inability to keep down any food, in which the styptic treatment was continued all the time with no good results. The koumiss treatment was followed by rapid improvement and complete recovery.

6. A case of pleura-pneumonia dextra followed by intractable vomiting and inability to retain food in the stomach, treated successfully by the koumiss. Equally favourable results, by the sole use of sparkling koumiss, were quoted by Dr. Jagielski in the following cases:

7. A lady, 66 years old, with pleuritis exudative dextra, a long sufferer from chronic bronchitis, with very severe vomiting, and scarcely any food in the stomach for ten days.

8. A case of old mitral incompetency, with anasarca and gastric catarrh, with constant vomiting.

9 and 10. Two cases of diabetes mellitus. Almost in a dying state from inability to retain food on the stomach and consecutive irritation.

Further, Dr. Myrtle's, of Harrogate, four cases described

(*a*) Abstract of a paper read in the Section of Medicine at the Annual Meeting of the British Medical Association in Manchester, August, 1877.

in the *Lancet* of December 12th, 1874, one of marasmus in the adult, with unchecked vomiting—successful; one of pyæmia, with sickness and unchecked vomiting—successful; one of phthisis (advanced) with ulceration of mucous membrane, diarrhœa and hectic—successful; one of rheumatic fever, with gastric irritability of a most formidable nature—successful; and Mr. Carter Wigg's case, of Southminster, Essex (see the *Lancet* of January 9th, 1875), of heart disease and albuminuria, with constant sickness, retching, and vomiting, likewise successfully treated with koumiss.

In concluding, Dr. Jagielski recommended the koumiss treatment as harmless at the worst, and the more rational means with which to commence the early and primary treatment of disease for which it is suitable.

THE PULSE-RATE CONSIDERED IN RELATION TO *POST-PARTUM* HÆMORRHAGE. (*a*)

By J. ASHBURTON THOMPSON M.D.

THE author began by referring to the well-known assertion that if, after delivery, the pulse beat at or about 100, the patient cannot be considered safe from hæmorrhage, which, on the contrary, is, in that case, to be apprehended. He then remarked that this assertion, which, if true, is of great value, is based upon the opinion only of a number of authors who do not offer any series of precisely recorded observations in support of it. The object of the present paper was to ascertain, from a number of records of the pulse-rate in various cases, beginning immediately after delivery, what is the behaviour of the pulse in uncomplicated cases, and what its behaviour in cases of *post-partum* hæmorrhage. The total number of cases dealt with was 63; 54 of these were cases uncomplicated by hæmorrhage, and 9 were cases of hæmorrhage of different degrees of severity, which were classified according to Dr. George Johnston's mothod, and, moreover, showed the exact amount of blood lost in each. The observations in both kinds of cases began two minutes after delivery, and were taken at short intervals during the first thirty minutes. At every observation the watch was used, the pulse counted during not less than thirty seconds, and the result written down at once. In cases of hæmorrhage the observations extended over a longer period. The 54 uncomplicated cases resolved themselves into three classes, as follows:—In the majority, or 39, the pulse fell within a few minutes of delivery by from 3 to 29 beats (average 13½), a reduction which did not always bring it below 100. In 6 cases it remained absolutely steady at the first observed, or initial, rate, and this was also not always below 100. In 9 cases a rise from the initial rate was observed, in this case, also, bringing the rate above 100. The author concluded that the pulse may rise from, fall from, or remain steady, at its initial rate after delivery; that it may rise to, fall to, or remain steady at, a point above 100; that it is very commonly irregular for several hours; that it may intermit, after labour uncomplicated by hæmorrhage or by constitutional disease. A table of the 9 cases of hæmorrhage was then shown, and the author said that for his present purpose he preferred to call them cases of *post-partum* inertia of the uterus, since that is the essential condition of this kind of hæmorrhage, and since he wished to exclude very carefully cases of hæmorrhage from lacerations of the uterus or other soft parts. From this table it appeared that degrees of hæmorrhage requiring active interference are compatible with steady pulse rates of 60 (1st degree), 70 and 76 (2nd degree), or with a rate varying from 96 to 108, as in one case of the third degree. The author then inquired whether the causes of *post-partum* inertia are always such as are likely to influence other parts of the system, and observed that this complication is known to occur under a variety of circumstances in which no condition common to all can be discovered. But he observed that shock to the system is often accompanied by relaxation of the uterus, and by five other cases he showed that the pulse follows a very marked course, steadily rising while the state of shock (and hæmorrhage) persists, and steadily falling as recovery from the shock sets in. Here a coincidence might be observed between the hæmorrhage and the pulse rate, but it was accidental merely, because both were results of the condition of shock common to all the cases. This description of a characteristic behaviour of the pulse in cases of hæmorrhage originating in shock (from laceration of uterus, sudden laceration of perinæum, concealed accidental hæmorrhage, or extreme systemic exhaustion from tedious labour) the author believed to be original.

(*a*) Read before the Harveian Society of London, Feb. 1878.

Clinical Records.

MERCER'S HOSPITAL, DUBLIN.

Under the care of Mr. O'GRADY,

Surgeon to the Hospital; Member of the Surgical Court of Examiners, Royal College of Surgeons.

THE following cases have recently been under observation in the surgical wards.

Severe Smashing of Left Foot consequent on a jump from a height.—A girl, æt. 23, whilst partially under the influence of liquor, jumped from a fourth-storey window into the area of the house. She seems to have first struck the ground with the left foot, and then to have fallen over heavily on the right side. When brought to the hospital, the foot was found to have lost all shape and form, it was a crushed bruised mass, the great toe lay transversely across the bases of the other toes, pointing directly outwards; the whole organ was enormously swelled, and when touched conveyed to the hand, in all directions, the sense of grating bones. Though the skin was badly lacerated and torn here and there, none of the fractures were compound. By manipulation the great toe was restored, and the foot gotten into such shape as was practicable; in the first instance it was merely steadied by loose bandaging to a high foot board adapted to one of the ordinary fracture boxes of the hospital, and cold lotions constantly applied; as the swelling began to subside, the hollow of the foot was kept carefully padded, and suitable pressure maintained by a shaped pasteboard splint on the dorsal aspect. The girl made an excellent recovery, leaving the hospital in twenty-seven days, with a well consolidated and shapely foot, no trace whatever of the accident recognisable, with every prospect of an unimpaired limb. The region of the right hip where she fell was severely contused; the trouble here, too, speedily passed away.

Perforating Wound of Foot.—This injury occurred in a lad, æt. 14, under the following circumstances. He was endeavouring to raise the body of a donkey cart, one of the wheels of which had came off, when it slipped from his grasp, and a bolt or rod of iron projecting from the bottom impaled the foot, transfixing the outer metatarsal space, and carrying before it and out through the sole a circular piece of leather, as large as a fourpenny bit, punched out of the "upper" of his boot, and which when the lad came to the hospital was projecting from the orifice of exit on the sole of the foot. At first iced- and subsequently cold-water dressings were applied; no bad symptoms of any sort occurred. When discharge was taken nine days after the accident, the little wound had very nearly healed.

Strangulated Femoral Hernia, Reduction effected after Tapping the Sac.—A woman, æt. 70, was admitted with strangulated femoral hernia of the right side; on this occasion it was three days "down," and the symptoms were very urgent, there was much local pain, constant and most distressing vomiting. Taxis, freely tried outside, was again unavailingly attempted. The sac was of large size, and contained a quantity of fluid; on tapping with a small hydrocele trochar some ounces of reddish fluid

escaped ; the gut was now easily reduced. The symptoms at once ceased, and the case did well.

Extensive Sloughing of Piles.—A source of material palliation occurred in a man, æt. 47, who from time to time had been under treatment for large masses of piles mainly intermediary. They were a source of much annoyance, principally from their bulk. Without obvious cause sloughing occurred, there being, when the man was admitted to the hospital, two large gangrenous masses extruding from the anus. These separated in due course, eaving clean granulating surfaces which healed steadily.

Excision Elbow was necessitated by extensive disease associated with necrosis of ulna, the patient being a strumous boy, æt. 8. The single posterior incision was selected ; convalescence, though tedious, was eventually very satisfactory ; when the boy left the hospital, some six weeks after the operation, his health had much improved, and though one small sinus (from which, however, there was scarce any discharge) still remained patent, there was considerable and increasing powers in the limb, with nearly normal control of motion.

Compound Comminuted Fracture of Leg, attended with much damage to soft structures and extensive comminution of both bones occurred in a groom, a healthy man, æt. 47, in consequence of a horse falling on him ; the accident was followed by diffuse and prolonged suppuration along the intermuscular planes, necessitating a stay of three and a-half months in hospital, ere satisfactory consolidation took place. A large piece of the tibia exfoliated.

Trismus following Severe Burns.—The patient here was a girl, a prostitute, æt. 19, whose clothes took fire whilst drunk, causing extreme and very deep burns of the right upper extremity and back. The tetanoid trouble became manifested at the end of a week, when the sloughs were separating. The treatment, mainly by chloral, proved unavailing, the patient succumbing on the fourteenth day.

ROTUNDA LYING-IN HOSPITAL.

Case of Arm Presentation in which Decapitation was practised.

Under the care of Dr. LOMBE ATTHILL,
Master of the Hospital.

Reported by JAMES C. CAMERON, M.D. Montreal.

ELIZA FEATHERSTONE, æt. 19, admitted 9th December, 1877, at about the eighth month of her first pregnancy. Patient had well-marked signs of secondary syphilis. She stated that the pains began at 3.30 a.m., and continued regularly and of good strength till 12.30, when the waters began to drain away ; the pains at once diminished in strength and frequency. On admission at 8 p.m., by means of internal and external examination, the child was found to be in the dorso anterior position, the os about the size of a sixpence, and the left elbow presenting. Although the elbow was made out, still the presenting part was so high, and it was so difficult to examine thoroughly, that chloroform was administered at 10 p.m., and the diagnosis cleared up. There being no doubt that the pelvis of the mother was roomy, the child premature, and probably dead, it was decided to wait in the hope that spontaneous expulsion might take place. At 11.30 p.m. the left arm descended and the hand protruded through the vulva. At 12 the temperature was 100·4°, pulse 112, pains short and chiefly in front. The patient was left undisturbed till 2.30 a.m., by which time the temperature had risen to 100·8°. and the pulse, though constant at 108—112, had become much feebler. The pains were almost constant, and occasioned her great distress, so that she kept rolling and tossing from side to side, crying out bitterly the while. The arm still protruded, and not the slightest advance had been made during the last three hours. Chloroform having been administered at 3 a.m., Dr. Atthill introduced his hand into the vagina and two fingers into the os, which was very rigid, and endeavoured, by combined internal and external manipulation, to push up the shoulder and bring down the head, but without avail. Next he attempted to pass up his fingers to seize a foot and perform ordinary version, but so firmly and so accurately were the walls of the uterus contracted about the child that no amount of force which he could apply made the slightest impression upon the child. The only alternative then being decapitation or evisceration, Dr. Atthill determined to decapitate. First, with a pair of long and strong curved scissors he endeavoured to divide the neck, but found it impossible to sever the neck with the scissors, and was obliged to resort to the blunt hook, by means of which he very readily separated the head from the trunk. The body was then without difficulty extracted, and immediately afterwards the head. The child was putrid. During the administration of chloroform her pulse became at several times indistinguishable, and on two occasions breathing ceased for a few seconds.

Dec. 11th.—A.m., temp. 100·8°, pulse 84 ; p.m., temp. 101·2, pulse 96. Feeling tolerably well ; complains a little of abdominal pain.

12th.—Temperature 100° ; pulse 86.
13th.—Temperature 100·2° ; pulse 90.
14th.—Temperature 99·6° ; pulse 100 ; slight rigor.
15th.—Temperature 99° ; pulse 90.
18th.—Discharged quite well.

Dr. Atthill, in his clinical lecture, pointed out that in cases of presentations of the upper extremities, where the child is premature and the pelvis roomy, it was right to wait and see if nature would effect delivery by "spontaneous expulsion" —that is, by the fœtus being expelled doubled up, the breech being gradually forced down. When the child is premature, and especially if it be dead, as was the case with this patient, "spontaneous expulsion" frequently occurs, but in this instance the pains were so inefficient that no progress was made, while the pulse and temperature rising simultaneously rendered delivery imperative. The difficulty, however, of effecting this was considerable ; the os was not more than half dilated, while, the waters having drained away many hours before, the uterus had contracted so firmly that it was closely moulded to the fœtus, rendering any attempt at turning impossible.

Dr. Atthill then pointed out that the choice under such circumstances lay between evisceration and decapitation, and commented on the numerous objections which existed to the former operation, and the reasons which induced him to decide on performing the latter. In this case he succeeded in severing the head by means of an ordinary blunt hook, but had the child been older, and not partially decomposed, it would not have proved an efficient instrument, and he would, under such circumstances, advocate Paget's method of decapitation by means of a piece of whipcord, which, being passed over the neck, should then, by a see-saw movement, be made cut through the neck. Decapitation once effected, no difficulty, as a rule, is experienced in extracting the body. The head, too, is generally removed without difficulty.

Transactions of Societies.

DUBLIN MEDICAL SOCIETY.

THE Fifth Meeting of the Session was held on Wednesday, March 6th, 1878, Dr. GORDON, President of the College of Physicians, in the chair.

DISTRIBUTION OF CHOLERA IN DUBLIN IN 1866.

Dr. GRIMSHAW made a communication to the Society on the subject of the distribution of cholera in Dublin in 1866, and its relation to the geological formation of the Dublin district, in which he gave details of the death-rate and geological formations of the portion of the Dublin district which were visited by the malady. The highest death-rate occurred in a district containing most pervious strata, and the greatest number of deaths occurred either on pervious strata or close to old river sources. The facts adduced by the writer of the paper concerning Dublin went to corroborate the views of Pettenkofer.

The PRESIDENT said he believed it was pretty well established that cholera kept to light gravel surfaces.

Dr. LALOR said there was one thing which struck him with regard to the paper generally, and that was that it excluded altogether what, to his mind, was a very important point in reference to the propagation of cholera contagion. He was a very strong believer in contagion, and his experience would lead any man who had similar experience to come to the same

conclusion—that cholera was a very contagious disease. The time allowed for making remarks on papers was too short to enable him to give the results of his experience, but he was a strong believer in contagion; and any theory that excluded the consideration of the theory of contagion, was, in his opinion, radically at fault. In reference to cholera following the course of being connected with certain strata—gravel beds and water courses—his earliest reading about cholera, calling now but the dim recollection to his mind, was that at that time cholera was considered to follow the courses not of extinct water beds, but of rivers, and at that time it was explained on the theory of contagion, which was then the favourite theory, and that cholera was carried along the course of those rivers which were covered rivers. In reference to the question in Dublin, with all respect for the reader of the paper, he would object to the use of the name altogether, for in his humble opinion there was no such thing as a river in Dublin (laughter.) The Liffey was an open sewer, the Dodder was not much better, and the Pottle was a covered-in sewer. In reference to the strata of Dublin, he was not a geologist, but as far as his experience went of the locality in which he resided—in the 56 acres of the Richmond Lunatic Asylum—all the gravel beds that he had been able to find were those of what was vulgarly called gravel bed. The Richmond Lunatic Asylum had a substratum of alluvial cultivated soil cultivated as market gardens. Immediately below these was generally a stratum of what was commonly called gravel, but what was really alluvial soil—rich garden soil. In some portions of the grounds there was a stratum of fine river salacious sand, which was only about one-and-a-half to two inches in thickness. In reference to what was called gravel, he would point out that there was no extent of gravel—that if there was any subsoil of gravel, as gravel was commonly understood (that was limestone gravel)—that the existence of such a bed was disproved by the fact of the exceedingly bad materials provided for their streets in Dublin. He thought one very considerable cause of the dirt and unwholesomeness of their streets was that they had no limestone gravel; that they had nothing to put upon their streets of a porous character, such as lime-stone gravel, which would empty the *brackish* surface water, whether that water was pure rain water or water impregnated with noxious matters; that they had no stone or gravel to empty that. The stone all around Dublin was calp—an exceedingly bad building stone—which was to a certain extent a pervious stone, but not a pervious stone of the same nature as lime-stone gravel, which allowed the percolation of fluid matter, whether that water was pure or impure. The stone was not of that nature, it was exceedingly soft, and in that way it was an exceedingly unwholesome material for the surface of their streets. As far as his experience went, they had no gravel as it was understood in the central part of Ireland, from which he came. They had no limestone gravel in Dublin, or within ten miles of it, and what was called gravel was either a mixture of calp or *aluminous* soil, or what was called blue marl, which was not gravel proper. As to cholera taking the course of old river beds, he would object to any general conclusions being formed upon that subject from the experience of one cholera outbreak in 1866; and he would also object to any general conclusion being formed that excluded the question of contagion. He would also object to any general conclusion being formed as to the city of Dublin on the ground of the general and indefinite use of the term gravel. Above all, and before all, he would object to any general conclusion being formed as to what caused propagation of cholera principally in the city of Dublin, in reference to water courses, whether open or closed, or extinct, which did not deal with the question as to what the definition of that water course was—whether it meant a river, simply meant what he said in Dublin was the true definition of its water courses—sewers either open or closed.

Dr. H. KENNEDY, in reference to the question of rivers being conducting agents for cholera, reminded the meeting of the very elaborate report of the late Dr. Graves. That was the point with which the writer started, and started in the strongest possible way. He (Dr. Kennedy) thought that in any discussion such as the present, the name of Dr. Graves should not be forgotten. He (Dr. Kennedy) had, at the time cholera first appeared in this country, been sent at one time to Finglas, and at another to Dalkey, and resided at both of those places, at each of which he saw the disease in a very virulent form, more particularly on the quarries at the last-mentioned place. With regard to the important question of contagion, it was discussed by the Society a few years ago, when medical officers who had seen cholera in India were present, and were unanimously against the opinion that it was contagious. He thought those were points which they should not forget in reference to the spreading of the disease. Any extension of epidemics should attack anything in the nature of a living thing. It should not apply to human beings alone. He could easily understand the circumstance of the increasing mortality amongst human beings, from their residence, civilisation, and other things; but any general theory that should be started about the causes of epidemics, should take in other creatures besides man. Epidemics were known to rage amongst the lower animals, just as amongst mankind. Otherwise how were they to explain the reason that birds of the air and fishes of the sea suffered so much. He thought theories on those points to be accepted, ought to take in every living thing. The remark applied even to vegetables.

Dr. CRANNY would like to ask Dr. Grimshaw whether he could give any information as to the districts outside Dublin, if cholera followed gravels in other parts of the country as well as in Dublin.

Dr. DARBY thought the Society was greatly indebted to Dr. Grimshaw for the paper, and for the attempt he had made to throw light upon a most obscure and difficult problem. Dr. Darby then spoke of a case of cholera that he had seen with the late Professor Smith in Red Cow Lane, Dublin, where an old man was dying in a corner of a small room, and the dead body of his wife lying beside him. There were such numbers of neighbouring young boys and girls about the place that they had difficulty in jostling their way into the room where the sick man lay. There were, as far as they could ascertain, no cases arising out of that case, and he thought they might fairly infer that if contagious, the disease would have spread amongst those people. He happened to be in Paris when people were dying very fast of cholera, and at the Hôtel Dieu, Charité, and three or four other hospitals, he saw all cholera cases brought in, without having any special cholera ward, and placed amongst fever and chronic cases. The authorities there evidently had no idea that cholera was contagious, or they would not have acted in the way he described. There was, however, one hospital in the neighbourhood of the Madeleine where there were cholera wards. He did not agree with Dr. Lalor as to his theory of contagion. He (Dr. Darby) had seen cholera on the banks of rivers, and he had seen it also on the tops of mountains.

Dr. WILLIAM MOORE thought it was desirable that they should have some idea of what was meant by contagion. According to his idea of Pettenkofer's theory, it, above all others, started the idea of contagion. He would certainly expect to find typhoid fever moving over gravel beds. He thought there could be little doubt that the virus passing from the patient at the beginning of the epidemic, was discharged into the gravel bed, where it underwent a process which rendered it fertile, and caused the disease to spread in the neighbourhood. If that was true he considered that the theory of Professor Pettenkofer would be strongly in support of the theory of contagion.

Dr. GRIMSHAW, in reply, said he stated in his paper that one of the points assumed was that the disease was contagious, and if cholera was not contagious, in the true sense of the word, Pettenkofer's theory would not hold water in any shape. He would have to account for it in a totally different way to what he did. The discharge from the patients' bowels, or the product of that matter, promoted cholera, and there was no other cholera contagion known. Dr. Lalor had told them very truly that there was no real river in Dublin. With reference to cholera following river courses, the disease followed the river course because it was the run of traffic, and it followed a river course in the same way as it followed a railway, and other lines of traffic, whether by rail, road, or river. That was admitted by almost all persons. He did not think any person had argued against cholera following the direction of great rivers, just in the same way that it followed the course of the Great Southern and Western Railway, which it undoubtedly did in the last epidemic, and also the road to Balbriggan. With reference to the geological strata of Dublin and gravel, Dr. Lalor evidently wanted a definition of gravel. Dr. Lalor, in speaking of gravel, had described a thing that was pebbles imbedded in boulder clay, and that was the same impervious strata that he (Dr. Grimshaw) had spoken of in his paper. Finglas was a cholera focus, and ought to have cholera, according to Pettenkofer's theory. Kingstown was, as most people knew, on granite, but Juggy's Well—a celebrated well there—proved by a rather serious ex-

periment to be one source of cholera. It broke out in Holyhead, and was brought thus from London to Dublin. But it was also proved conclusively that the water brought from Juggy's Well to the mail steamboats caused cholera on board boats; and upon inquiry, that water was condemned. He held that an isolated case did not prove the absence of contagion; but it was very hard to trace contagion. They did not know anything about the incubation stage of cholera. Pettenkofer seemed to think it was indefinite; and moreover that writer held the opinion that cholera contagion might be carried by a person who did not get cholera himself at all. He thought Pettenkofer had so far proved a good case, and he had not been shown to be wrong; and the end of his (Dr. Grimshaw's) paper was simply to test Pettenkofer's views by the experience of Dublin, and the test of Dublin was very much in favour, he believed, of Pettenkofer's theory.

The Society then adjourned.

WEDNESDAY, APRIL 10, 1878.

REPORT OF THE SELECT COMMITTEE ON LUNACY LAW.

THE Lunacy Committee who met last session, and occupied their time in examining Government officials, discharged and *quasi* lunatics, and medical officers of asylums, have at last issued their Report. We must confess that, considering the vast amount of evidence placed before them, they have utterly failed to grasp in a material way the question *sub judice*. The points to which the Committee direct our attention are: 1st. Whether a possibility exists of persons being unduly deprived of liberty by a false allegation of lunacy? 2nd. Whether persons properly detained are placed under restraint of a nature calculated to retard their cure and consequent discharge? 3rd. Whether undue obstacles are opposed to their release when restored to sanity? The Committee received upon each of these questions copious evidence, and made a careful examination of such, which consisted in petty squabbles between officials and medical experts, always ready to air their grievances, exaggerated statements of discharged lunatics, dating back for a considerable period of years, opinions expressed by various medical specialists, but giving results diametrically opposite. With such a blaze of bewilderment it is not to be wondered at that the Committee were unable to separate the wheat from the chaff, and arrive at a definite and rational conclusion. With regard to the first of the questions to be considered—the possibility of detaining a person on a false allegation of lunacy—the Committee state that the allegations of *mala fides*, or of serious abuses, were not substantiated. To the second and third questions, we reply that, if no serious abuses were proved, there could be no instances of improper detention or treatment. The Committee seem to have failed to distinguish between harmless and dangerous lunatics, and regard the two classes as being in different categories. We maintain that if a man is of unsound mind there is every justification for his detention in an asylum as a lunatic, and such an act is not an improper or illegal one. If we were to accept the view that harmless lunatics ought not to be confined in asylums, we should at once liberate all our demented cases, and simply retain as inmates acute and dangerous lunatics. Such an interpretation of our lunacy law is not, happily for society in general, as well as for the protection and, well-being of the lunatic, acknowledged by those who are competent to give an opinion on the subject. The Committee pass on to compare the trifling nature of the abuses alleged, as compared with the horrible cruelties with which lunatic asylums were conducted less than half-a-century ago, and the exposure of such atrocities before select committees of the House of Commons on various occasions. They contrast the chains and ill-usage then employed with the occupation and amusement "which may be said to be the universal characteristics of the system in this country at the present day."

Attention is drawn to the importance of the treatment of insanity in its earliest stage, and the Committee suggest that provisions might be made for this in many cases outside the precincts of an asylum, but in the majority such a proceeding would be impossible, as also the establishment of an intermediate hospital, which was suggested to the Committee. Objection is raised to the power given in Scotland by which a certificate of emergency may be signed by the medical officer of the asylum. The Committee state that the order upon which the patient is admitted should continue in force for a limited period not exceeding three years, and at the end of this time a special report of the patient's state should be made by the medical superintendent, and repeated at the end of each subsequent year. This report is to be sent to the Commissioners. It is difficult to realise such a suggestion emanating from the Committee. What do the Committee imagine the Commissioners are doing at each of their six visits made to all lunatics asylums during the year? Can they be aware of the fact that the Commissioners in Lunacy carefully examine each individual case, and inspect the case-book kept at the asylums, and they do so in a thoroughly effectual way? Any case they are not satisfied with

they instruct the medical officer to send a full statement of such to the board. The Committee now go on to consider the signing of the order of admission, and here again they fail to grasp the subject. They recommend that the "Order" should be signed by the nearest relative of the patient, and that the reasons should be given stating by what authority he intervenes. Such a provision is happily found in the present Order, to which it would have been advisable for the Committee to have referred before drawing up their Report. One good suggestion is, however, made that the person who signed the Order should visit the patient once in every six months, and this applies not only to those in asylums, but to single patients in unlicensed houses. We cannot, however, endorse the expressed opinion of the Committee that the detention of persons should cease "as soon as they are no longer dangerous to themselves or others, and are not likely to be benefited by further detention." The Commissioners are to decide when the time has come for this discharge. We think that the present provisions in our lunacy law are sufficient, which enable the Commissioners to discharge a patient, if after two visits, a certain interval elapsing between them, they can detect no symptoms of insanity. We think it would be a most hazardous practice to empower the Commissioners to discharge a lunatic on one single visit. We are unable to endorse the opinion that a report should be sent to the Commissioners of patients kept under restraint in private families "not for profit." If a person has a sister or a near relative insane, and is desirous of maintaining them at home, there appears to us to be serious objection to making such a proceeding a formal one, and quite undesirable. We, however, agree that the patients who are confined in religious houses, should be reported to the Comissioners. We cannot see the force of the argument that the Commissioners in Lunacy should, in the discharge of their duties, follow the example of the Chancery Visitors, which consists in the personal examination of the lunatic. Here a lamentable want of knowledge is again shown by the Committee. Both the Chancery Visitors and the Commissioners in Lunacy inspect and personally examine the lunatics, the former those found lunatic by inquisition, and the latter not only these, but also the other inmates of asylums; whilst the former visit the asylums *once* a year, and the latter *six* times. An amalgamation is suggested between the two bodies of officials—the Chancery Visitors and Commissioners in Lunacy. We heartily endorse the statement that in the admission of boarders into licensed houses it is unnecessary to restrict this privilege to those who have been placed under certificates. By such a provision we shall be enabled to admit into our asylums dipsomaniacs—a want long felt. This is by far the most important suggestion made by the Committee. These voluntary boarders have to be reported to the Commissioners within twenty-four hours from admission. We are glad that the condition of private asylums is considered to be such as to receive the laudatory remarks of the Committee. Suggestions are made that in each of the rooms of asylums a notice should be affixed setting forward the right of appeal of patients by letter to the Commissioners. It is also suggested that all letters which have not been forwarded to the persons to whom they are directed, should be sent to the Commissioners in Lunacy. We cannot, however, see the advantage of this, for at the present time all letters which are not forwarded are placed before the Commissioners at the time of their visit. Most serious consequences would result from following out the suggestions made that patients on their discharge should have access to all documents connected with their detention; this would give rise to endless family disputes, and probably, in some cases, to a life-long misery. We think that the present system of permitting patients to inspect their certificates upon which they have been admitted is quite enough for the purpose, and that any further steps would be inadvisable. We cannot regard the Report, taken as a whole, as one likely to be of any benefit. The suggestions, with the exception of that which refers to "boarders," are mostly useless, and a certain inability is shown throughout the inquiry to grasp the question at issue. The Committee have utterly failed in establishing any cases of illegal detention on which assumption they started, and it is a satisfaction to us to know that after a long and tedious inquiry by a Parliamentary Committee, no material alteration has been suggested in our present Lunacy Laws.

THE PARLIAMENTARY DEBATE ON VACCINATION.

None of our readers will be surprised that the long debate on the vaccination laws which took place in the House of Commons resulted in the discomfiture of those who would relax the penalties at present inflicted upon parents who disobey the law. Mr. Pease formally moved the second reading of the Vaccination (Penalties) Bill, the object of which was to amend the law with reference to accumulating penalties, by providing that no parent should be liable to be convicted for neglecting to have a child vaccinated, or for disobedience to an order directing vaccination if he had been previously fined 20s., or had been twice adjudged to pay any penalty. On the House dividing, however, the motion was lost by a majority of 189, 271 voting against the second reading, and only 82 for it. Many hon. members, among whom was Mr. Gladstone, took part in the debate, but very few reasons were brought forward in support of the motion. Mr. Pease himself merely stated that a large number of children had died in consequence of the operation, but he did not adduce any evidence in support of this assertion. He also expressed his conviction that if the proposed bill were passed it would put a stop to a great deal of public agitation. Mr. Forster was convinced of the great efficacy of vaccination as an almost certain remedy for one of the most terrible scourges that afflicted humanity; but it could not, he said, be concealed that there were people who entertained conscientious objections to the practice, and their constant prosecution excited more sympathy and agitation than would be the case if the state ceased to interfere after a certain amount of punishment had been inflicted. Nor did Mr. Gladstone bring forward any better arguments in favour of the bill; but he drew the attention of the House to the

fact that they had a vaccination law working in two ways in the two kingdoms of England and Scotland. In the former country they had cumulative penalties, but Scotland (or Ireland) were not subject to cumulative penalties.

But, while not even a plausible reason could be given for relaxing the penalties to which the opponents of vaccination are now exposed, very cogent reasons were given why Mr. Pease's bill should not become law. Even allowing that the subject of cumulative penalties might be dealt with, the Government could not give their assent without qualifications to the present bill, as they were convinced that if any material change took place the Anti-Vaccination Society would readily relieve persons from the payment of penalties, and thus nullify the Act of Parliament. Besides, as Sir J. M'Kenna said, and we ourselves urged more than twelve months ago, the passing of this bill would be offering a positive premium to obstinate resistance to a law which had done much for the health of the people. Or, as Mr. Mitchell-Henry put it, it was an immoral thing to say that persistence in refusal to obey the law should produce an immunity from its penalties. Dr. Lyon Playfair also remarked that the passing of the bill would be "selling a legal indulgence to disobey the law."

It will, however, be in the memory of our readers that we have all along thought it at least questionable whether some alteration should not be made in the law so far as these accumulating penalties are concerned. There can be no doubt that they excite a good deal of animosity and hostility among the opponents of vaccination; that they are regarded as a species of petty and unwarrantable persecution on the part of the State, and that even as the law stands, these repeated penalties are often paid by the Anti-Vaccination Society. Besides, it is evident that the Government have some misgivings on the subject, for we find Mr. Sclater Booth himself confessing that in some cases it would be advisable if fewer prosecutions had been instituted, and he "would be glad if magistrates had a discretion as to issuing an order or enforcing a penalty." Surely this admission is nothing less than a confession of weakness on the part of the Government, of which the opponents of vaccination will not be slow to take advantage. Either the law respecting accumulating penalties is just and politic, or it is not so. If just and politic, why should the authorities flinch from acting upon it; and why should it, at the option of the magistrates, be at one time compulsory, and at another time a permissive law. As we long ago suggested, the difficulty might, in any future amendment of the law, be got over by not prosecuting the offender more than once, or at most, twice; with this provision, however, that in the event of his child contracting and dying from small-pox, he should be liable to a very severe punishment, equal to or approaching that at present inflicted in cases of manslaughter. If a parent wilfully neglects to have medical advice for his sick child, he is, in the event of that child dying, in the eyes of the law, guilty of manslaughter, and we are at a loss to conceive why a parent who allows a child to catch and die from small-pox, when such an event might have been certainly prevented by vaccination, should not be subject to a similar punishment.

THE ART OF PRESCRIBING.

In a recent number of *Guy's Hospital Gazette*, it is mentioned as a fact that candidates for the second M.B. Lond. are often incompetent to write an ordinary prescription; a remark which is also applicable to a large number of far less ambitious candidates than those who aspire to the above degree. It is indeed a very common complaint against half the students who appear before the different Examining Boards. Nor is it difficult to account for this deficiency in a somewhat important part of a medical man's education. A writer in the journal just mentioned, says, that as a teacher of pharmacy, he is able to understand the difficulties which lie in the way of a medical student acquiring the art of prescribing. He states that there is not—as there should be—any provision made for the systematic teaching of this art; that a good knowledge of Materia Medica, Practical Chemistry, and Practical Pharmacy, is essential to a good prescriber, and that unfortunately these subjects are taught in the first year, when the mind of the student is not sufficient to grasp the importance of the facts which come from the lecturer. He further, and very justly, adds that Practical Pharmacy is very rarely well learnt by students, and that the art of prescribing is almost entirely left to be picked up by him as best he can.

With some of these remarks we unhesitatingly agree, but notwithstanding the importance of the subject, there are serious objections to either making special provisions for teaching the art of prescribing, or to the teaching of Materia Medica and Chemistry at a later period of the curriculum. As far as lecturing and demonstrations go, there ought to be a good opportunity for the student to acquire a knowledge of this subject during the course of lectures, and the course of instruction that are respectively given on Materia Medica and Practical Pharmacy; and that he has not this opportunity is not so much his own fault as that of the lecturers themselves. It is well known that no subject of study is so unpopular among students as that of Materia Medica. Students that have distinguished themselves for their knowledge of Medicine, or Surgery, or Pathology, have shown a lamentable amount of ignorance of the doses of, and the mode of prescribing, the commonest drugs. Students who have passed with credit the higher examinations of our great universities, have, through their ignorance of Materia Medica, had the mortification to be rejected at the Apothecaries' Hall. One reason, no doubt, of this, is the fact that to the medical student Materia Medica and Pharmacy is only one, and the least attractive one, of many subjects to which he has to give his attention; and consequently at the end of his curriculum of studies his knowledge of pharmacy and the Pharmacopœia is such as the most ordinary candidate for the licence of the Pharmaceutical Society would be thoroughly ashamed of. On the other hand, the future chemist knows that to pass the examinations of this Society he must have a good knowledge of practical pharmacy and pharmaceutical chemistry; consequently his whole attention is given, and therefore successfully given, to those subjects. So again the candidates for the "Assistantship" of the Apothecaries' Hall always show a far better knowledge of these subjects than those medical students who go up for the primary examination. But this consideration, it

will be said, is one that cannot be got over, as Materia Medica, &c., will always form but a part, and a very unpopular part, of the medical student's studies. Then all the more reason, we say, for making the lectures on these subjects a little more attractive and more practical than they are at present. All the less important drugs and the less important preparations should be kept in the background, all petty details respecting the natural history, preparation, chemical constitution, &c., of a drug should be strictly avoided. On the other hand, all the great and indispensable medicines should be brought into bold relief. A knowledge of their action, their uses, and their official preparations should be, by all means, impressed upon the student's memory. He should be taught the most usual and most useful combinations of medicines; and there should be a *practical demonstration* of those which are incompatible with each other.

Lastly, the abolition of the system of apprenticeship is another reason why many candidates for a medical diploma or license are imperfectly acquainted with practical pharmacy. Formerly every student had, before he entered a hospital, an opportunity of compounding medicines, and of getting a good practical knowledge of the doses and uses of drugs, of the chief constituents of the most important compound preparations, of the mode of making tinctures, infusions, &c., and of the most common combinations of one drug with another. He had probably made several tinctures, rolled out thousands of pills, spread a few plasters, and dispensed a variety of mixtures, draughts, powders, &c. The sons of medical men do not in this respect labour under the same disadvantage as do the sons of gentlemen who do not belong to the profession; for they have in most cases the same opportunities of learning practical pharmacy as were offered under the old system of apprenticeship. But the boy who directly marches from his school or college to the hospital, enters upon his medical curriculum without the slightest knowledge of materia medica and pharmacy, and other and more attractive subjects engaging his attention, the former are either altogether neglected, or studied in a very perfunctory manner.

It is to be hoped, therefore, that more attentien will be given to these subjects at our medical schools, and that the usual course of instruction on Materia Medica, as well as that on Practical Pharmacy, will, in future, at least, enable a candidate to write an ordinary prescription.

Notes on Current Topics.

Dr. Bucknill on Insanity in Relation to the State.

Last Friday, Dr. Bucknill delivered at the Royal College of Physicians the first of his lectures on insanity in its relation to the state. The subject, said the lecturer, was one of great importance to the general practitioner, who was liable to be called upon to give his opinion in the witness box; besides which, his peculiar position as the family medical man gave him an advantage over the expert, inasmuch as he had the opportunity of seeing and treating the incipient lunatic at an early and more remediable period of his disease. It was very difficult, however, to say what insanity is, and what it is not, and the difference of opinion among lawyers and physicians, as to the proper definition of the term "insanity," arose from the fact that the two professions looked at the subject in very different lights, the physician looking chiefly at the causes, the symptoms, and the treatment of insanity, while the lawyer had, in his definition, to regard the question of the actual existence or not of the disease, and the conduct of the supposed lunatic. In all such questions there should be a compromise between the two professions, each borrowing from each other's peculiar department of knowledge, whatever facts threw most light upon any particular case. A contrast was then drawn between our past and present knowledge of insanity, but whereas formerly, as in the time of Willis, our knowledge was very gross and imperfect, so that the above physician divided all states of insanity into the *high* state and the *low* state, there was now a vicious tendency to refine too much, and to multiply unnecessarily the different forms of the disease. This error, said Dr. Bucknill, arose from the habit of indulging too much in hypotheses, of admitting such terms as "the insane neurosis," and of extending the meaning of insanity beyond its legitimate limits. When the profession did this, it was only right for the lawyers to step in and interfere.

In reference to another subject, the lecturer remarked that the question of capital punishment had very much influenced the decision of professional witnesses with regard to the responsibility of criminals, although, it was clear that medical witnesses had nothing to do with the kind of punishment that would be inflicted upon the criminal if found guilty. With regard to the law of insanity in questions of criminal responsibility, the guilt or innocence of the prisoner was made to turn, upon whether the prisoner at the time of his committing the crime knew right from wrong. But, as Dr. Bucknill long ago insisted, criminal responsibility depended more upon the power than upon the knowledge of the criminal; and for some time this legal definition of insanity has given much dissatisfaction even to some of our most eminent legal authorities. Lord Chief Justice Bramwell was satisfied with it in a logical point of view, but in actual practice found that it did not embrace those concrete cases that came before him for judgment. Lord Chief Justice Blackburn also acknowledged the great difficulty there was in making a satisfactory legal definition of insanity, and in the case of a woman who had murdered her infant during a fit of temporary insanity, he directed the jury in her favour, on the grounds that although she did know what she was about, the crime was evidently committed under an uncontrollable impulse. The lecturer then dwelt at some length upon the law as amended by Sir Fitzjames Stephens, according to which the question of criminal responsibility depended upon *whether the criminal was, from a diseased state of his mind, prevented from controlling his own conduct.* Lastly, attention was drawn to the difference between our knowledge of the morbid anatomy of insanity, and that of the true pathology and practical diagnosis and treatment of insanity. The former was certainly only in its infancy, but much had been done to extend our knowledge of that rational pathology upon which we base

our judgment with regard to the existence, the nature, and the causes of the disease. It is, moreover, to be regretted that owing to absence of inquiry on the part of prison authorities, and others, and to want of funds, there is often a miscarriage of justice, and that as Lord Godolphin Osborne once said, a large number of criminal lunatics have been found guilty, and have suffered the extreme penalty of the law, while on the other hand, many perfectly sane criminals have been released on the plea of insanity.

The Coming Arctic Expeditions and Total Abstinence.

THE summer of 1878, says a lay contemporary, promises to be a memorable one in the annals of Arctic discovery, or at least, attempts at discovery. The Dutch have almost completed their preparations for a northern reconnaissance. Professor Nordenskjold is preparing to make an effort to sail along the Arctic shores of Europe and Asia. The Americans have a sort of tentative expedition afloat; and now Mr. Gordon Bennett, of the *New York Herald*, has chartered Sir Allen Young's yacht, *Pandora*, for an Arctic cruise, under United States naval officers, but at his expense. This praiseworthy liberality and enterprise in the cause of geographical research is sometimes spoken of as a characteristic of our day. On the contrary, the last generation or two has seen little of this kind of thing. "Government" is called upon to do everything; and, as a matter of course, centralisation increases, and lack of public spirit diminishes. In former times was witnessed a very different state of affairs. Take Arctic Exploration for example. Most of the great expeditions of the middle ages, and even on to within forty or fifty years ago, were undertaken either by private companies of "gentlemen adventurers," or at the cost of munificent merchants. Sir John Ross named Boothia Felix, after Sir Felix Booth, a London distiller, who had defrayed the greater portion of the expense of the expedition which discovered it. Mr. Grennell fitted out two expeditions for searches after the remains of Franklin's crew. Mr. Oscar Dickson, a Scoto-Swedish merchant of Gottenburg, has liberally aided more than one Arctic expedition; while the German merchants, and the Messrs. Gibbs, of London, to their own great loss, have fitted out at least two similar expeditions. English yachtsman, such as Birkbeck, Lamont, Leigh Smith, and Wiggins, have also been active in the same direction; and now if Mr. Bennett succeeds in despatching the *Pandora* this summer, he will have added one more to the list of geographical expeditions originated, and the costs of which were defrayed, by private individuals.

In connection with these expeditions there is one subject which is not only of interest, but of vital importance, viz, should alcohol be served out as part of the daily rations supplied to the men, or should its use be entirely dispensed with? We have evidence of the strongest character from Arctic voyagers against its use.

Dr. John Rae, formerly in the Hudson's Bay service, who conducted many expeditions in the Arctic regions, ascribes the scurvy that attacked Captain Nares' late expedition to the grog and salt provisions. He speaks thus of his own experience:—"I may mention that I am not habitually a total abstainer from the use of wines and spirits, although I, as well as my fine fellows were so—not from necessity, but choice—on all the Arctic expeditions in which I was engaged. Although now about a quarter of a century older, were I going on another Arctic expedition I should again be a teetotaller, so perfectly am I convinced, after many years experience, of the bad effects of alcoholic drinks in a cold climate."

The late Arctic expedition, under Sir George Nares, furnishes us with some facts of a suggestive and striking character. There were six total abstainers amongst the number of explorers; five adhered to their resolution and principles; the scurvy did not attack them; the sixth was induced to take alcohol during a temporary attack of illness; he subsequently suffered from the scurvy. The total abstainers were living under the same conditions as the other members of the crew. They were equally exposed to hardship, and deprived of lime juice. The question then suggests itself, if all the men alike were without lime juice, and under similar conditions, in their journey over the ice, how happened it that the teetotallers escaped the scurvy whilst the alcoholists contracted it?

Can it be said definitely it was the use of rum which caused the disaster? There can be no doubt from the following evidence that the reduction in the quantity of spirits administered was beneficial, for Sir George Nares says:—"The ration of spirits was reduced from two-thirds of a gill (given in former expeditions) to one-half daily, and this only drunk just before retiring to rest, and never whilst the men were travelling. Each sledge carried extra tea in lieu of the usual mid-day allowance of spirits; and both men and officers were unanimous in favour of the change."

How can the difficulty be solved? How test the value of alcohol and total abstinence in the Arctic regions?

There is one way, and we think it is well worthy of the attention of total abstainers, to discuss it before another expedition sails. Though the Government may consider the proposal, it will probably not meet with the approval of the authorities, but the total abstinence party might induce some private individual or firm to enter into the scheme.

We propose then that one vessel shall go out on total abstinence principles, manned by a teetotal crew, composed of picked men who have adhered to their principles for years, and who are willing to put their convictions to the severest test it is possible to devise. On board this vessel alcohol shall not be used in any form, or under any circumstances.

We cannot be accused of asking men to recklessly expose their lives in defence of their theories, for we have sufficient evidence already that alcohol is not a necessity for enabling men to bear up against fatigue or hardship either in temperate or cold regions.

The Americans have sent out whaling expeditions on somewhat similar principles, and we have every reason to believe that the men have not suffered in consequence. We offer this suggestion to the leaders of the total abstinence party, and we have no doubt they will be able to elaborate the scheme, and carry it to a satisfactory conclusion.

Provident Dispensaries.

AT the Annual Meeting of the Charity Organisation

Society on this day week, the further extension of provident dispensaries became a prominent question. The Chairman, Lord Aberdare, said he hoped to see hospitals, which had done a world of good, supplemented by the establishment of provident dispensaries. He censured those who, being able to pay, were the recipients of gratuitous medical relief; adding, that if a reform in this direction were brought about, it would be attributable to the exertions of the Charity Organisation Society, since it had so earnestly sought to establish a system of provident medical relief in this metropolis. Such institutions were generally established in the Welsh collieries.

Sir William Gull, in an earnest and forcible manner, fully endorsed the views of the Chairman, and moved the following resolution :—"That this meeting is of opinion that the establishment and extension of provident dispensaries would be the most important means of developing self-reliance and improving the condition of the people, and accords its support to the society in its efforts in that direction." He said he came there to advocate the cause of the poor, who would, he conceived, be largely benefited by the establishment of provident dispensaries. There was great difficulty in distributing the relief letters to hospitals—so much that he had himself once suggested that they should be scattered broadcast amongst the applicants, and that those who secured them should not be attended to, they being obviously the strongest. There were a million of persons receiving gratuitous medical relief in the metropolitan hospitals, but more relief and more efficient advice could be given at the local dispensaries. The poor should not be neglected ; they should be sought out for the purposes of medical relief, and if there were no higher motive to promote dispensaries, the rich should remember that diseases generated amongst the poor gradually and insidiously spread themselves over every other class of society. Sir T. Fowler Buxton seconded the motion, which was carried unanimously.

The Tax on Tobacco.

It was very generally supposed that one way in which the deficit of £3,500,000 would be met, would be by increasing the taxation on spirits, the more so as there has been lately such an outcry about the increase of intemperance among all classes of society, especially the lower classes. To the surprise of many, spirits have been passed over, and the more harmless tobacco has this time been chosen as a convenient means of enriching the Exchequer. As a lay contemporary observes, tobacco has been unaccountably lost sight of in the list of candidates for additional duty, because perhaps, it is thought that any further charge would act as a stimulus to smuggling. In a political point of view no doubt the choice is a happy one, considering how universal the habit of smoking has become ; but from a hygienic standpoint we should have preferred taxing the spirits instead of e tobacco. There is, as we have before remarked, too much smoking, especially among the more idle and well-to-do classes ; but while the new tax on tobacco will have little influence in keeping the habit within the bounds of moderation, as far as the middle and higher classes are concerned, it will tend to [illegible] the consumption of tobacco b tha e class of people among whom smoking is excusable, and to many of whom it is almost as indispensable as their daily food. With many smoking has been regarded as the parent of drinking ; but they may perhaps, with more truth, be regarded as antagonistic of each other. Great smokers are usually very moderate drinkers, whereas great drunkards are very indifferent smokers.

Wool Sorters' Disease.

The influence of occupation upon health and disease has received the attention of sanitary reformers, and we have, in consequence of their efforts, a diminution in the number and fatality of trade diseases. The great obstacle to the prevention of the waste of life occurring in many of our manufacturing industries arose in the past, from the apathy and indifference of the workmen themselves. They looked with suspicion upon contrivances designed to preserve their health, preferring suffering, disablement, and even premature death.

Amongst the more familiar trade diseases we may mention grinders' rot, match makers' necrosis, painters' colic and palsy, and miners' nystagmus. The affection commonly called sorters' disease has some distinctive features, for, whilst in other trade diseases we find premonitory symptoms and local lesions indicating danger—thus affording the victim a chance of abandoning his employment—in this case a man in previous good health may be at work in the morning and dead at night. We are now alluding to the form to which sorters of alpaca, camel-hair, and mohair are exposed. In the earlier days of the introduction of alpaca or mohair into textile fabrics the deaths were more frequent, but improved sanitary appliances have diminished the mortality, though not to such an extent as we could desire. In the districts where it is largely employed it is not by any means an unfrequent cause of death, and thus the life of the sorter must necessarily be one of risk and anxiety, for there is suspended over him, like the sword of Damocles, the shadow of the same visitation which has, perhaps, carried off many of his fellow workmen and companions.

It is natural that such a disease should have excited much interest, not only amongst the *employés*, but amongst medical men ; but though much valuable information has been gathered about it, much yet remains to be done in regard to clearing up its real nature and causes. It is, or should be, a preventible disease, and we are not saying too much in affirming that it ought to be stamped out from our medical vocabulary, and become a memory of the past, and we say this considering our advances in preventive medicine. If the exact cause of the disease were known chemistry might assist by submitting the fleeces to some agent which would destroy the poison without injuring their texture or commercial value. At present it would seem, on the evidence we have, that the disease resembles, in many respects, septicæmia.

We think the time has fully come for a scientific report on this disease. The medical practitioners resident in alpaca districts might usefully contribute to the elucidation of its pathogenesis.

The Future of Workhouse Infirmaries.

THE recommendations made by the Local Government Board, through its representatives, Dr. Mouat and Mr. Sendall, that the Leeds workhouse infirmaries should be placed under the control of the medical officer, marks a very important epoch in the history of these institutions. The separation of the infirmaries and medical department from the interference of the workhouse master is a step which will be hailed with satisfaction by all Poor-law medical officers, and it is a pleasure to learn, on the evidence of two such authorities as Dr. Mouat and Mr. Sendall, that this change will be effected, not only with economy, but with advantage to the sick poor.

Medical officers will thus be placed on a somewhat similar footing to that of medical superintendents of Poor-law asylums, and we shall be still more glad to hear that their salaries will also more closely approximate. We believe this is the first workhouse in the provinces which has considered the adoption of this scheme. If a success, it should extend to all infirmaries containing 200 beds.

We shall return to the subject again.

International Medical Congress for 1878.

AMSTERDAM has been fixed on as the place of meeting for the sixth congress, and a committee has been formed, consisting of the following members, to make all the arrangements—

President—Professor Donders, Utrecht.

Members—Dr. Van Cappelle (La Haye); Dr. Fabius, Professor Hertz, Professor Stokvis, Professor Tilanus, Dr. Zeeman (Amsterdam); Professors Heynsius (Leyden), Huet, Huizinga (Gronigen), Koster (Utrecht), Rosenstein (Leyden), Sanger (Gronigen), Snellen (Utrecht); Dr. Ramaer (La Haye).

Secretary-General—Dr. Guye (Amsterdam).

The Congress will last one week, commencing Sunday, Sept. 8, 1878: the official languages will be French and German. All communications relative to the Congress should be addressed before June 1, 1878, to the Secretary-General. We trust fuller particulars will be advertised in the English medical journals.

Mutual Benefit Societies.

THOUGH they manage some things "better in France," yet it seems, the question of mutual benefit medical societies affects the profession in a somewhat similar manner to what it does in England. *La France Médicale* is our authority for this statement.

M. Emile Genevoix deals with the subject as it affects the *pharmacien*, but he also tells us that it presses, none the less, upon the physician. In certain industrial centres, where clubs are numerous, a somewhat similar system to that in England of employing a special medical attendant is in vogue. The rights of combination we do not dispute, nor do we intend to discuss them, but there can be no doubt that the medical man who undersells his medical *confrères* and gives cheap medical advice cannot be mindful, either of his own honour or of his own interests. We have sadly too much cheap doctoring, too much abuse of medical charity, and we regret to find that it extends to other countries, but it only proves that human nature is much the same, no matter under what clime, and that parsimonious dealings with medical men are not an insular inheritance.

The London Hospital.

THE meeting in aid of the London Hospital has not been held a day too soon, for there are few hospitals the funds of which are so low and so out of proportion to the magnitude and indispensable character of the charity. We were, therefore, glad to see that the meeting, the object of which is to secure a maintenance fund of £25,000 a year, for five years, was both numerously and influentially attended. The first resolution, moved by the Duke of Cambridge, K.G., was: "That the London Hospital—the only large general hospital for the eastern part of the metropolis and adjacent suburbs, comprising a population of one million—occupies a position of paramount importance among the charities of London, and is worthy of the liberal support of all classes. The second resolution pledged the meeting to do all in its power towards securing the efficient maintenance of this institution. The third resolution, moved by the Duke of Westminster, K.G., was: "That whereas the income derived from the London Hospital from endowments is less than £14,000, while its necessary expenditure is nearly £44,000 a year, a special fund be established for maintaining the charity during the next five years, and that a committee of appeal be formed in order to obtain contributions for the purpose. As our readers are aware, the hospital has 790 beds, which require, as above stated, £30,000 annually more than the fixed income of the charity. The deficiency will compel the committee to close 400 beds, unless such a sum be raised by the end of the present year, and £25,000 a year is the smallest sum that can be considered necessary. Not so long ago the hospital contained only 500 beds, and perhaps some may think that the authorities have increased their number of beds before duly considering where the funds would come from to support them. A hospital charity, however, especially such a large and useful one as that of the London Hospital, is a very buoyant institution; and notwithstanding £25,000 a year seems a heavy demand upon the charity and liberality of the public, we have no doubt but that the appeal of the above committee will be liberally responded to. At the end of the meeting several large sums of money were subscribed, ranging from £200 to £5,000. Great economy has always been practised in the management of the hospital, and therefore it has all the more claim upon the support of the public.

The Prize for Hydrophobia by the Royal College of Physicians.

WE are informed that the Royal College of Physicians is empowered to offer a prize of £100 on the subject of hydrophobia.

1. The Council has recommended as general principles that the prize be offered for an essay on the "Nature of Hydrophobia, its Causes, Prevention, and Treatment."

2. That original investigations be regarded as of especial value as deciding on the merits of this case.

3. That the prize be not awarded unless an essay of sufficient merit be presented.

The Council is authorised to lay down in detail the points on which information is especially required.

The present epoch promises to be a fertile one in the

literature of rabies. A stimulus being given by our "Special Reports" on the disease, there is ample information now at hand for the compilation of an essay. We trust the College of Physicians will faithfully carry out the motto, *Palmam qui meruit ferat.*

The Inquest System in Dublin.

THE following facts have come recently to our knowledge :—

A woman named Teresa Gourlly, aged 56 years, a spinster, and by trade a tailoress, lived at 35½ New Row West, was apparently in good health up to the morning of March 9th. No medical man was in attendance on her, but it is believed she had attended at a dispensary, the locality of which had not been inquired into. Persons intimate with her, and residing in the same house, were unaware of her having suffered from weakness, faintness, or palpitation. On the morning of the 11th of March, deceased not having been seen about as usual, a resident in the house entered the room and found her apparently asleep, but really dead. She lay in her day clothing on the bed, there were no appearances of convulsion or of her having suffered pain, no wound, no blood. The police were sent for, and after a time the coroner for the city of Dublin and his standing medical witness arrived, who, after examining the exterior of the body, gave the woman who had first found her dead a certificate, the purport of which was that an inquest was unnecessary, and that the cause of death was "apparently internal hæmorrhage from rupture of a blood-vessel."

We note these facts as being illustrative of the inquest system peculiar to Dublin, and of the danger that such a system may produce a totally inaccurate decision as to the cause of death, and very possibly a miscarriage of justice. *Firstly*, the police, in summoning the coroner, omit to give, as they are bound to do by the law, to the coroner the most important part of the "information which they may be able to obtain touching . . . such death," *i.e.*, the name of the medical practitioner who had been in attendance on the deceased. *Secondly*, the coroner does not, as he is bound to do by the law, summon "a legally qualified medical practitioner being at the time in actual practice at or near the place" of death, but brings with him a gentleman who resides at a distance, and can have no possible knowledge of the circumstances, saving hearsay evidence, thus excluding the testimony of the only person who can have any real acquaintance with the cause of death. *Thirdly*, in order to avoid the expense of an additional medical witness and the trouble of a *post-mortem* examination, the coroner and his medical witness undertake to diagnose "rupture of an internal blood-vessel," it being just as probable that the cause of death was an overdose of some medicine or suicide by poison.

How many of such guess verdicts appear on the inquest-roll of the City of Dublin in the course of a year we know not, but there can be no doubt that the illegal employment of one individual as a salaried medical witness tends directly to the multiplication of such haphazard statements of the causes of death.

The police of a city in which such a system is tolerated needs to be vigilant, for we strongly suspect that many a corpse is quietly disposed of under the guess system, which could tell a tale of crime if the cause of death were investigated. It would be decidedly a safer arrangement if the Corporation which patronises such a system were to decree that in doubtful cases the coroner, his medical witness, and the police constable should toss "odd man out" whether the cause of death was accidental or criminal.

Tooley Street Redivivus.

HAPPY is the nation that numbers among its lawgivers even three master-minds capable of rising to the exigencies of a situation and settling a disputed question off-hand by a stroke of their pen! Dull-headed doctors, obtuse chemists, and even slow-minded judges, have been for years puzzling their brains over the settlement of the counter-prescriber's privileges and the rights of the holders of German and Yankee degrees. At length, we rejoice to learn, the Columbus of the occasion has arisen in the guise of a druggist, named Fitch, who has, not exactly passed (the rest is a matter of form), but promulgated a bill which is to set the dispute to rights at once, and in the most satisfactory manner. With the caution and modesty distinctive of a noble mind, the Fitch has not revealed his legislative panacea until it had been seen and approved by "a graduate of a foreign university and a registered chemist." The precaution was unncessary, but it was safe, and, therefore, wise, and the approval of these eminent and astute advisers will, no doubt, make the passing of the bill a foregone conclusion. The "Fitch" bill is brief and pointed—*rem acu tetigit.* It simply enacts "that no penalty (for illicit practice) shall be recoverable from any one holding a diploma from any colonial or foreign university, *whether registered or otherwise.*" Also that none of the penalties in illicit practice "shall extend or be construed to extend, or prejudice, or in any way affect the trade or business of a chemist and druggist in the buying, preparing, compounding, dispensing, *counter-prescribing*, and vending of drugs . . . but that all registered chemists shall be exempt from" such penalties. Also that the Apothecaries' Company shall be forbidden to prosecute without permission of a general meeting, and without notice to the offender.

This is all! The difficulty is gone. *Abeit! evasit!! erupuit!!!* Bravo Fitch! Honour to the graduate of the foreign university!! Glory to the registered chemist!!!

UNDER the will of Dr. Cameron, late of Richmond, New South Wales, the University of Edinburgh becomes possessed of £2,000, "the proceeds of which are to be given annually to such member of the medical profession as shall be judged by the Senatus Academicus, to have made the most valuable addition to practical therapeutics during the year preceding such adjudication."

IN the House of Lords on Friday last, it was stated by the Earl of Minto, that of the 16,323 deaths in Glasgow in one year, no fewer than 3,601, or 22 per cent. were uncertified. His lordship very properly called the attention of Her Majesty's Government to this serious state of things, and an inquiry was promised.

The Opening of Museums on Sundays.

THE opening or not of museums on Sundays has just been a subject of debate in the House of Lords, but with no more satisfactory result than that which has characterised previous debates on the same question. If the opinions of medical men were canvassed on the subject, they would be probably all in favour of the movement. Judging from the petitions that have been presented to Parliament, the working classes are themselves, to a great extent, averse to the opening of museums on Sundays; but this may be owing partly to religious influences, or to their jealousy of any innovation that may seem to trespass upon their hours of rest. Besides, the working classes are, in a certain measure, like children, and do not know what is good for them, physically or mentally. During fine weather innocent out-door recreations are certainly to be preferred, as being most conducive to the health of individuals who have been confined indoors for nearly all the week. But then we must recollect the number of rainy days we have in the course of the year; and surely their minds would be better employed and diverted, more refreshed and invigorated, their taste more improved and their sympathies more widened, if working men and women were allowed to pass on those wet days a few hours in one of our great museums, than will be the case if they are obliged either to remain moping at home, or to expose themselves to the demoralising influence of a public-house. As Lord Truro justly remarked, the majority of working men had never been in the galleries or museums, and could not judge of the benefit they would receive from them. The question was not whether places of exciting amusement should be opened on Sundays, but whether places of innocent recreation and instruction should be opened.

The Simon Testimonial.

OUR readers will remember that last year, when Mr. Simon retired from the office of chief medical adviser in Her Majesty's Privy Council, a proposal was made to raise a subscription in order to present that gentleman with some testimonial in token of his efforts on behalf of the medical profession, and of sanitary science in particular. On Saturday last, a meeting of the committee and subscribers to the fund was held at the rooms of the Social Science Association, Adelphi, Sir James Paget in the chair, when a report was presented, stating that the amount of money required had been liberally subscribed. Resolutions were passed adopting the report, and thanking the subscribers, and Mr. Woolner for so successfully carrying out their wishes, as well as Dr. Acland, chairman; Dr. Farr, treasurer; Mr. Alfred Haviland, hon. sec.; and Mr. J. Robinson, assistant secretary, for their services. The bust was on view, and was universally admired. It was subsequently taken to the Royal Academy, where it will remain for some time. Its ultimate destination is the Royal College of Surgeons.

THE loan by the Metropolitan Board of Works to the Asylums Board for the enlargement and building of asylums has been reduced, at the instance of Her Majesty's Treasury, from £100,000 to £50,000.

A Case of Rabies at Chelmsford.

SINCE our "Report on Rabies or Hydrophobia" has been concluded, we are informed that a case has been under treatment at Chelmsford, and that up to the present the man may he said to have recovered. We have not, as yet, the means of ascertaining whether it was a genuine case of hydrophobia, or what remedies were adopted, and we look forward with interest to a full report of the case from the medical officer in charge. The facts, as far as we can learn, seem to be—that a man, named Thomas Hicks, whilst in the act of eating his dinner, was seized with strong convulsions, followed by apparent lock-jaw. He was removed to the Infirmary, where he developed pronounced symptoms of hydrophobia, requiring two men to watch him day and night. It was known that he had been bitten by a dog about eight weeks ago; all hope of his recovery was abandoned, but despite the acute agony he has undergone he is now believed to be making rapid progress towards convalescence.

We laid down in the clearest and most unmistakable manner, in our "Report," that rabies was *a curable and controllable disease*, and if it turns out to be a genuine case, we shall congratulate, not ourselves, but the profession on the acquisition of a new fact to encourage us in dealing with this disease. If our suggestion, in reference to the appointment of official inspectors for every reported case of rabies were adopted, the authenticity of this case would be stamped with an *imprimatur* which would place it beyond further dispute, for many of the previous recoveries have been questioned, and if it were a spurious case, a similar beneficial result would follow. We would also impress the necessity of employing, in any future cases, the remedy we laid before the profession, and as we gave the fullest particulars as to method of administration and dose, there should not be any difficulty in its practical administration, if not by the medical attendant in charge, by some consultant, either from London or the provinces.

Sulphocyanides in the Urine.

SULPHOCYANIDES have long been known to exist in the saliva, and in works on medical jurisprudence analysts are warned to distinguish between it and meconic acid. Gscheidlew and Munk have recently, but quite independently, proved that these salts are also present in urine. In the human urine ·0225 grammes of sulphocyanic acid in the form of sodium salt are found in 1,000 cubic centimetres.

HOSPITAL SATURDAY, like Hospital Sunday, seems to thrive in Birmingham better than in any other large town. The sixth annual collection in the workshops of that town was made last week, and without the ostentatious display of flags, dressed-up boys, and ladies touting in the streets, £2,543 were collected from the *bona-fide* working man. This is as it should be—from the first we have deprecated the mode of collection of the London Hospital Saturday Fund, which with twelve times the population, does not collect so much from the working classes as Birmingham. The working man in the metropolis is, we are convinced, as willing to contribute as his provincial *confrère*, but bad management and exorbitant expenditure at the outset

have deprived him of that confidence which engenders special interest.

THE annual rates of mortality in the principal foreign cities, according to the last weekly official returns, were in Calcutta 34, Bombay 44, Madras 62 ; Paris 27 ; Geneva 29 ; Brussels 37 ; Amsterdam 31, Rotterdam 33, The Hague 27 ; Copenhagen 22 ; Stockholm 24 ; Christiania 21 ; St. Petersburgh 59 ; Berlin 26, Hamburg 29, Dresden 33, Breslau 28, Munich 43 ; Vienna 34, Buda-Pesth 46 ; Rome 42, Naples 42, Turin 29, Venice 38 ; New York 25 per 1,000 of the population.

THE rates of mortality last week in the four principal cities of the United Kingdom were 26 in London, 27 in Edinburgh, 28 in Glasgow, and 29 in Dublin, per 1,000 of the population. Of the other large towns, Portsmouth gave the most favourable return with 16 per 1,000, Brighton and Plymouth being at the bottom of the list with 32 each, Birmingham and Oldham 31, and Liverpool 30.

WHOOPING-COUGH is still fatally prevalent in London, 158 deaths having resulted from it last week ; whilst 48 died of small-pox, and 47 of scarlet fever. This mortality from whooping-cough was greater than it has been during the last 39 years.

THE second reading of the Endowed Hospitals and Schools Bill (Scotland), was passed in the House of Lords on Friday last.

Correspondence.

SEA VOYAGES IN PHTHISIS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—A short time since the following case came under my observation, whilst Surgeon in the Union Steamship Company's steamships which sail between Southampton and South Africa, and I think is conclusive evidence of the benefit derived from well-chosen sea voyages in cases of phthisis. A gentleman, æt. 29, suffering from phthisis in the second stage, was recommended by an eminent physician to proceed to South Africa, for change of climate, and to avoid the English winter. A very small cavity had been diagnosed in the apex of the left lung. On coming on board, the state of the patient was as follows :—In the left sub-clavicular region, there was well marked comparative dulness, and occasional crepitus could be distinctly heard ; mucous râles could be heard over the upper half of the same lung ; the right lung was healthy. There was frequent cough, and marked irritability about the glottis ; the sputum was moderately abundant, the dyspnœa was perceptible, though not a marked symptom ; the pulse ranged from 104 to 112, and night sweats were more or less frequent. There was loss of weight ; the weight being 144½lbs.. The temperature was normal (98·2°) in the morning, but at bedtime, ranged from 98·9° F. to 99·28 F. The increase of evening temperature, as may be seen, was small, but still amounted from ·5 to ·75 of a degree Fahr. The patient was, moreover, weak, and the appetite indifferent.

The treatment adopted, was a tablespoonful of cod-liver oil three times daily ; half a pint of new milk twice daily, and occasional doses of pancreatic emulsion and pancreatine, so highly recommended by Dr. Dobell. In the tropics, the cod-liver oil was reduced to half the daily allowance, *i.e.*, 3vj ; to this treatment was added the recommendation that the patient should be on deck as much as possible. On the morning of the sixth day, the ship arrived at Madeira, where the patient had a walk on shore, and expressed himself as feeling stronger, but as the thermometer was 86° F. in the shade, and the *leste*, a dry, irritating, wind blowing, not much exercise was taken. On the night following, the thermometer in the axilla registered the normal temperature, 98·4° F., and continued normal throughout the voyage.

On the 11th day of the voyage, the cough and sputum could be observed to be somewhat diminished, and by the 18th day, both the cough and sputum had practically ceased ; the sputum entirely so, and the cough had diminished to a very slight bronchial irritation in the morning. On the 20th day of the voyage, the ship arrived at St. Helena, when the patient was able to walk 1¼ miles up the very steep street of James Town, and return to the ship, a distance altogether of 2½ miles. On the 26th day after leaving Southampton, the ship arrived at Cape Town, when on examination it was found that the patient had gained 3½ lbs. in weight (*i.e.*, from 144½ to 148 lbs.), that the crepitus in the left sub-clavicular region had ceased, and that the moist râles had become changed into dry sounds.

On taking a survey of the improvement of this case as a whole, I think it will be admitted that it was very satisfactory. On the 7th day after starting, the temperature had become normal ; the cough and sputum had practically ceased on the 18th day, and at the end of the voyage, weight, appetite, and strength, had all increased.

I consider South Africa much superior to Madeira as a health resort, on account of the greater dryness of the climate, the greater movement of the air, and the necessarily longer voyage to reach it. In Cape Town at midsummer, the dry bulb in the middle of the day is generally about 78° F., and the wet bulb 68° F. ; this gives a relative humidity of the air of 56 per cent. saturation ; further up country the humidity of air is frequently 50 per cent. saturation. I would not, however, recommend Cape Town as a residence for the consumptive, as it is badly drained, and the mortality from zymotic disease frequently alarmingly high. Port Elizabeth, 500 miles from Cape Town, is on a barren sand hill, and the neighbourhood almost destitute of trees or vegetation. East London is a somewhat similar place, but smaller, and as there is a very dangerous bar at the harbour's mouth, it is impossible to land except in a life-boat. Durban and Port Natal are much prettier places, but I consider them too hot, except for three or four months in the cool season, June, July, and August.

I would suggest as a residence for the phthisical, Wynberg or Constantia, both suburbs of Cape Town, and about 10 miles distant, easily accessible by rail, or the small town of Worcester, 108 miles from Cape Town, and also accessible by rail. This small town is about 1,000 feet above the sea level, and there are three comfortable hotels in it kept by Englishmen. Having visited all the above places, I speak from experience of them, and I am convinced that as South Africa becomes better known, it will be more appreciated as a health resort.

Yours, &c.,

J. G. THORNLEY, M.D.

GLYCERINE IN THE TREATMENT OF INTERNAL HÆMORRHAGE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—A few weeks ago, having to treat a case of "bleeding piles" in the person of a young married woman, who had been suffering from them for a couple of months, I thought it a good opportunity to test the suggestion contained in the January number of the *Practitioner*, 1878, from Dr. Young, of Florence, as to the good effect of glycerine in such cases. I gave two drachms three times a day, in simple mixture. At the end of a week relief was complete.

Your obedient servant,

Dronfield. JOHN W. MARTIN, M.D.,

THE Official Medical Register for 1878 was issued on Wednesday last, a month later than usual. We hope it will be correspondingly correct with the extra time taken in its passage through the press.

Literature.

ZIEMSSEN'S CYCLOPÆDIA. (a)

VOLUME XV. of this well known Cyclopædia will be looked forward to by most readers with much interest. Nor will they be disappointed with it. It is written by Prof. Bartels, of Kiel, and Prof. Ebstein, of Göttingen. The work of the first is translated by Dr. Southey, of St. Bartholomew's; the latter by Dr. Bertholet, of Philadelphia. The work of Bartels covers the physiology of the kidney, albuminuria, and those forms of renal disease generally known as "Bright's disease." Ebstein describes the other diseases of the kidneys, as pyelitis, calculus, &c.

Of albuminuria, Bartels says: "In speaking of albuminuria and the value we must attach to the presence of albumen as a symptom of disease, it behoves one to remember that this substance does not only find its way into the urine as a result of pathological changes in the kidney, but may come from the pelvis of the organ, from the ureters, from the bladder, or even from the urethra itself. This is too little borne in mind by the profession at large." Then he goes on to say: "In every case the explanation of the excretion of albumen by the kidneys must be sought for in disturbance of the processes by which the secretion of urine itself is affected." Of such search he says, "careful examination has taught others as well as myself, that it is no such rare event for kidneys to secrete albuminous urine during life, which yet after death present no trace of histological alteration, either in their glandular cells or in their interstitial tissues. While, on the other hand, kidneys which are extremely diseased, whose gland cells and interstitial frameworks exhibit pathological degeneration of extremest kind, may furnish a urine totally free from albumen." This must be rather a disturbing statement for those complacent individuals who make their decision as to the presence, or absence of kidney disease turn on the behaviour of the urine in a test-tube. In speaking of high pressure on the glomeruli as a cause of albuminuria, he relates a case where albumen was absent when the patient kept his bed, but at once became present when he got up. By this means he was once detected in getting up when bidden to stay in bed. After pointing out the form of albumen produced by a meal of highly albuminous food, he speaks of "albuminuria occurring exceedingly frequently in persons who are suffering from some severe febrile movement. In these cases it is due to the extremely high elevation of the temperature of the body, and to its long maintenance, be the cause of the fever what it may." Albumen is present in the urine when the tension in the arteries is great; it is then only found in small quantities. He further states, "it is not an altered blood pressure only, but also an alteration in the actual filtering apparatus of the glomeruli, which, if any, must be the source of the albuminuria in the inflammatory affections of the kidneys." Again, "one can always suppose that the epithelia of the renal tubes furnish a part of the albumen—that part which under the stimulus of inflammation is excessive, and beyond the needs of their nutrition. The share which they take up, but cannot appropriate, and so shed out again into the scanty urine, adding just thus much to its albuminous contents." The last word on the relations of albuminuria to disease of the kidneys has evidently not yet been spoken. Of tube casts he writes: "Now, what interpretation are we to attach to the presence of casts in the urine? Certainly, no more than this, that the person who passes them is suffering with true renal albuminuria. But the presence of casts themselves does not, in the slightest degree, appoint the nature of the cause at work in producing the albuminuria. At the same time, the value of the characters of casts in assisting us to make a diagnosis is very great."

Under the heading of Passive Hyperæmia of the Kidney, he classes the cyanotic induration of prolonged venous congestion, as in permanent cardiac lesions especially of the mitral valve, separating it from kidney diseases proper. In speaking of this change he says: "So far as my experience extends, uræmic symptoms are never associated with heart disease, unless some other complication beyond mere cyanotic induration co-exists, and this fact Traube has already insisted upon." He states, "the albuminous urine of acute nephritis always contains casts, but these vary greatly in number." In speaking of the acute parenchymatous nephritis of pregnancy, he writes: "The fact that relapses of the nephritis are not unfrequently observed in recurrent pregnancies, is certainly worthy of notice. This appears to indicate the existence of some special individual predisposition. It may not make itself felt in every pregnancy."

There are some cases on record which prove that a nephritis may complicate one pregnancy, and be absent in the next, but may occur again in the third or fourth. From this it is certain that there is something more in the relation of pregnancy to nephritis than the mere pressure on the renal veins—the accepted hypothesis.

When treating of chronic parenchymatous disease of the kidney, he commences by formally recognising the work of Dr. Samuel Wilks, and gives our distinguished countryman his due, with a generosity not always shown by German writers to observers in this country. Prof. Bartels holds that the chronic condition may, in some cases, take its origin in an acute attack; but this is not its common origin. He holds that marsh miasm is a frequent cause of chronic renal changes. He writes the following important passage: "Digestive disturbances set in pretty early in some cases, and a failing or capricious appetite, or even slight dyspeptic symptoms may attract notice even before œdema directs attention to the kidneys. The patient, with especial frequency, experiences a positive repugnance for animal food." This is a fortunate choice on the part of the organism, for nothing taxes the impaired kidneys so much as the functional duty of excreting the waste of albuminoid foods. In discussing the treatment of this condition, he says: "The pallor of the mucous membrane will always inform us of the diminution of the red blood-cells produced by the albuminuria, and this is an indication for the employment of ferruginous preparations. I do not think that it matters specially what particular preparation is employed; in deciding this, I am always guided by the individual cases. But it appears to me of importance that these chalybeate preparations should, under all circumstances, be introduced into a full stomach. Beyond this we need only endeavour to supply whatever preparation the patient best tolerates."

Granular, or contracting kidney is quite a separate disease from the one just spoken of, and Bartels holds that it begins and follows its course quite independently of the process of diffuse renal inflammation. He writes: "My own experience entirely contradicts Gull and Sutton's assertion that contracting kidney is 'a disease of old age.'" He stoutly maintains that it is not produced by the abuse of spirituous liquors. In contrasting German opinions upon renal cirrhosis with English ones, the difference of the disease in the two countries must ever be borne in mind. Thus Bartels admits: "In Germany, where gout is so much less common than in England, much less attention has been given to the relations of this kidney disease to gout. Among my own patients there was only one gouty subject—a high official of 52 years of age. But I have certainly had small opportunities of studying true gout, and am, therefore, from my own experience, in no position to judge of the frequency of renal disease in gouty subjects." Of its progress he writes: "Genuine contracting kidney may have existed for a considerable time, and may have reached a serious degree of development before the patient becomes aware, by any kind of symptom, that his health is no longer as good as it used to be." Cerebral apoplexy is often the first indication. The common symptoms are palpitation, uneasiness, or a feeling of want

(a) "Ziemssen's Cyclopædia." Vol. XV.—Diseases of the Kidney. Pp. 783. Sampson, Low, and Co. 1877.

of breath. Chronic bronchitis is a common outcome of it. Attacks of dyspnœa, exactly like genuine asthma, are common in the advanced stages. At other times there are severe headaches, especially migraine. Vomiting, and an intolerable itching of the skin are not rarely met with. Though short, this section, devoted to the progress of the disease, is most excellent.

The relations of hypertrophy of the left ventricle to renal cirrhosis are well put. In the section devoted to treatment it is more than ever necessary that the reader bear in mind that renal cirrhosis in Germany takes the anæmic form, while in England the gouty form is by far the most common. If this be forgotten the reader will be apt to get harm rather than good from this section.

So much has been said on albuminuria and renal cirrhosis that the rest of the book must be but briefly alluded to. Amyloid degeneration of the kidneys is contrasted with renal cirrhosis in an instructive manner. In speaking of the treatment of amyloid disease, Bartels writes: "Preventive treatment is certainly at present the most powerful weapon against this destructive process; *and herein I include, above all other things, a more thorough radical treatment of syphilis, that scourge of our age, than is at present ordinarily practised.*" He advocates Ricord's plan of a prolonged mercurial course.

At this point Bartels closes, and Prof. Ebstein takes up the suppurative diseases of the kidney, pyelitis, nephrophthisis, degenerative processes of the kidney, tumours of the kidney, of the pelvis, and the perinephritic tissue, together with foreign bodies in, parasites of, and anomalies of the kidneys.

The chapter on cancer of the kidney is well worth careful perusal; so also is that on gravel, called here nephrolithiasis. He thinks movable kidneys may be either congenital or acquired. If this latter half is reviewed but briefly, it is not because its subject-matter is not important, or that it is not well done. The part written by Prof. Bartels is more interesting to the English reader.

This volume is one of the best of the series, and we strongly recommend its perusal to all those who have invested in this Cyclopædia, or who can get access to it.

THE DEEDS AND NEEDS OF HYGIENE. (a)

From the pretentious title of this pamphlet, as well as from the high position occupied by its author as Chairman of the Section of Public Health, American Medical Association, we were led to anticipate some valuable information respecting past, present, and future sanitation, but, with the exception of a very cursory sketch of the discovery of inoculation and vaccination, some vague observations about what he is pleased to term "acclimation," and a few words laudatory of a series of entities called by the writer "germ annihilators," the sanitary science of the past and present has been left to be taken for granted; and, as regards the "needs" of hygiene for the future, Dr. Hunt lays down for our guidance a few common-place aphorisms —undeniable no doubt, but very trite indeed, and to be found in the ordinary text-books on public health. As specimens of the author's style, which is eminently characteristic, we append a few extracts from the address. We do so without comment, believing that they speak for themselves. We are told of an eminent sanitarian, a "General Pleasanton, who basks in the Arcadia, and perhaps Utopia, of actinic rays" we learn that there is "a coordination and concatenation of circumstances which frames mischief by a law;" that the unholy alliance consists of "a virulent contagion, a favouring personal receptacle, and an incubatory vicinage or abiding-place." We hear of "Gilpin rides after contagium," and are informed of the fact that "Variola, in its incidents, seems to tell us that the substitution and abortion of disease have a wider range than that of subcutaneous infusions and replacements," whatever they may signify.

We may add that we have yet to learn that the fact of Dr. Jenner having written a work on the cuckoo, and of his having in consequence thereof been elected a fellow of the Royal Society, has any bearing, direct or indirect, on the "Deeds and Needs of Hygiene.

(a) "The Deeds and Needs of Hygiene." An Address by Ezra M. Hunt, M.D., Chairman of the Section of Public Health, American Medical Association. 1877.

THE IRISH PHARMACEUTICAL CALENDAR. (a)

The Society, which has superseded the Apothecaries' Company in the control of pharmacy in Ireland, shows encouraging progress, and the account of its stewardship which it is able to give, is quite sufficient justification of the passing of the Act which called the Society into existence. Its two first years of life have brought to it 158 licensed pharmaceutists, and 101 members, of whom 21 were named in the Act and the rest elected since its passing. The financial condition of the Society is very satisfactory, its cash balance having nearly doubled within the year. On the whole, it cannot but be gratifying to the profession to know that after many years of neglect pharmacy is now receiving the attention in Ireland which it deserves, and that the dispensing of prescriptions is now on a much safer basis than it has been for a very long period.

(a) "A Calendar of the Pharmaceutical Society of Ireland.' Corrected to December 31, 1877. Vol. ii. Dublin University Press. Cr. 8vo, pp. 82.

Short Notices.

(1) "Aids to Surgery." By George Brown, M.R.C.S. London, Baillière, Tindall, and Cox. 1878.

(2) "On the Indications for the Use of the Trephine, derived from Cerebral Localisation and the Relation of the Cranium to the Brain." Translated from the French of Dr. Samuel Pozzi, by Thomas M. Dolan, L.R.C.P.E., &c. London: Baillière. Tindall, and Cox. 1878.

(3) "Indigestion and Diet." By John Dewar, L.R.C.P.E. London: Hardwicke, and Bogue. 1878.

(1) The Student's "Aids Series," we notice with pleasure, are not intended to supersede the ordinary treatises on disease, or to curtail in any sense *reading;* they are designed, as their name implies, to aid in bringing to a focus the knowledge derived, both from the perusal of books, and from practical observation of disease. On examination, the student will, by their help, be able, clearly methodically, and tersely, to answer the questions put to him.

The first part of "Aids in Surgery" seems well adapted for this object. A brief, though clear and accurate description, is given of some of the ordinary surgical diseases, thus affording the means of refreshing the memory and of economising time, which becomes valuable to the student about the period of examination.

We object to "cram" books, but works of this class cannot be included in such a category, and we, therefore, can confidently recommend "Aids to Surgery" to the class for whom it is intended.

(2) For many years the use of the trephine has been in abeyance, but the modern theories on motor centres, derived from a deeper and more extended study of the brain, have brought it again prominently before the notice of the profession. Cerebral localisation, as it is called, has during the past few years, attracted the attention not only of the anatomist, but of the physician and surgeon, and we have many valuable treatises and records, as the result of their observations and experiments. The French school has taken up this study with avidity, and we

have in this pamphlet a very able summary of the views, theories, and facts, in connection with the subject.

The general practitioner, whose time is so occupied, will be able in this work, to obtain a correct idea of how far cerebral localisation, will be able to assist him in the presence of the complications and accidents which so often come under his notice, whilst at the same time he will keep himself *au courant* with the latest literature of the day on this question.

The translation of such pamphlets we consider a great boon to the profession, as they familiarise us with the opinions of the French school of medicine, and this *brochure* is singularly opportune as the subject of motor centres is on its trial: It contains a clear, concise, and scientific *exposé* of the literature of the subject.

(3) There can be no doubt much injury is inflicted on the system by injudicious food, and one of the greatest difficulties medical men experience, is in persuading their patients to adopt a proper dietary. The profession has been accused of not paying sufficient attention to this subject.

Indigestion is consequently a disease much prevalent, and the pamphlet of Dr. Dewar will be especially useful to the dyspeptic, as it contains a large mass of sound and practical advice on regimen. It was intended as a guide for his patients, in order to avoid the necessity of verbal or written directions, but it is well deserving of a more extended circulation.

Medical News.

The Registration of Deaths.—On Thursday last a deputation from various friendly societies waited on the Registrar-General, at Somerset House, and represented to him the practice of registrars of death distributing blank forms of certificates to agents and collectors of friendly societies and others, and urged that the practice should be discontinued, on the ground that it opened the door to fraud by offering to unprincipled persons the temptation to forge certificates of death, in order to obtain payment from friendly societies. The Registrar-General said he would take the matter into consideration, and issue instructions to the registrars throughout the kingdom.

Gleanings.

Prevention of Arsenic Poisoning.

THE poison most commonly used for criminal purposes is arsenic, its tastelessness preventing the victim recognising it. In view of this, Dr. Jeannel, of Paris, proposes that druggists shall sell arsenic to the public only when so combined that it immediately attracts attention when added, either by accident or design, to food. The plan has not been overlooked, for there is an officinal mixture in which the arsenic is combined with peroxide of iron and a small quantity of aloes, but it is not sufficiently characteristic, and he calls attention to a mixture termed Grimaud's mixture. This consists of one centigramme of iron sulphate and one of potassium cyanide to each gramme of arsenious acid, forming a light-blue powder. On being moistened, however slightly, it becomes of a rich blue colour, whilst the taste is so distinctly chalybeate that it is impossible to overlook its presence in any article of food. It has the advantage of not altering or interfering in any way with the therapeutic properties of the arsenic.

Plans of Perspiration.

Le Progrès Médical, as quoted in the *Scientific American*, publishes a communication from M. Aubert, which describes a plan by which the distribution and activity of the sweat glands of the skin may be approximately mapped out. The method is as follows: A piece of white paper is applied to the skin, and maintained in contact a few minutes. The sweat, as it issues from the follicles, slightly moistens the paper at points corresponding to their orifices. A dilute solution of nitrate of silver is then brushed over the paper, and the nitrate becomes converted into a chloride from the chloride of sodium in the perspiration. The chloride of silver blackens upon exposure to light, in this way mapping out the distribution, &c., of the sweat glands. With the aid of this test paper, M. Aubert has studied the secretions in nævus, ichthyosis, pelade, erysipelas, scabies, lupus, favus, herpes, psoriasis, &c., and finds that, as a rule, irritations of the skin completely suppress the perspiratory secretion, and that even when the irritation ceases, some time elapses before the secretion reappears. In cicatrices many of the glands disappear, but those which remain, secrete more profusely than before.

The Photo-Chemistry of Vision.

RECENT researches by Boll, Kühne, and Ewald, make it very probable that a photo-chemical process takes place in the retina in each act of vision, and that the material sensitive to light is provisionally accumulated, while it is regenerated after each act of vision. M. Donders has also observed that if the eye be exposed to a gradually increasing impression, a moment comes when nothing can be seen, and it can then be demonstrated with the ophthalmoscope that the vessels of the retina are empty of blood, which would indicate that the visual material passes directly from the blood into the retina, and is replaced from the blood. Some experiments in support of this view have been recently made by M. Exner. In one of these the field of vision was divided into a white and a black half, and a white circle was brought into the black half. This was at first covered, however. The eye was kept fixed on the boundary of the two halves until the white appeared nearly black. The screen of the white circle was now removed. The circle appeared distinctly white, and only lost its whiteness gradually. This is explained by supposing that the supply of visual material in the retina, which, with the defective circulation, was not made good, was consumed in the one-half of the field of vision, but in the other black half could still serve for perception of the white circle.

Quinine in India.

THOUGH the cultivation in India of the best quinine-yielding species of cinchona (*C. officinalis*) has not proved a success, it is satisfactory to know that one species at least thrives most abundantly in the Sikkim plantations. From a paper read at the last meeting of the Pharmaceutical Society by Mr. Wood, the Government Quinologist in India, it seems that out of a total of about three million trees, comprising four or five species of cinchona it is estimated that there are as many as 2,500,000 belonging to the species *succirubra*. It is from this bark that the now well-known "cinchona febrifuge" is prepared. This substance, according to many well known medical practitioners in India, possesses to so very nearly the same extent the anti-periodic properties of quinine that it may be safely substituted for the latter in the treatment of ordinary febrifuge and ague. Five thousand pounds of this febrifuge, we are told, has already been made and issued, and it is now being made at the rate of four thousand pounds a year; the demand, however, is so rapidly overtaking this scale of production that a further extension will shortly be necessary. For use it appears in the form of a fine white powder, which, however, becomes in a short time of a pale buff tint. It does not agglutinate even in the Indian climate. It is freely soluble in weak acids, and is readily taken up by lemon-juice, which constitutes a pleasant vehicle for its administration.

The Development of Tænia.

AT a late meeting of the Parisian Academy a note by M. Redon communicated experiments on the ribbon-like development of cysticercus in the human subject The writer swallowed cysts collected from human beings and gave some to pigs and dogs. Man alone offered a nidus favourable to the development of these parasites, and yielded cucurbita. This proves that the tænia solium may proceed from a cysticercus, and that the cysticercus of man is not the same as that of the pig.

NOTICES TO CORRESPONDENTS.

☞ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

READING CASES.—Cloth board cases, gilt-lettered, containing 26 strings for holding each volume of the MEDICAL PRESS AND CIRCULAR can now be had at either office of this Journal, price 2s. 6d. The postal regulations not allowing the Journal to be stitched, these cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

NOTICE TO SUBSCRIBERS.—Subscribers who have not already paid their subscriptions for last year are reminded that they are now due, and should be sent to the publishers, who will be happy to acknowledge their receipt.

HUNTERIAN SOCIETY.—This evening, at 7½ o'clock, Council Meeting. 8 p.m. Mr. Davies-Colley, "On a Rheumatoid Affection of Joints in Women." Dr. Galabin, "On the Treatment of Prolapsus Uteri."

EPIDEMIOLOGICAL SOCIETY.—This evening, at 8½ o'clock, the President, "On the Plague and Typhus Fever in India."

CLINICAL SOCIETY OF LONDON.—Friday, April 12, at 8½ p.m., Mr. Nunn: (1) "Electrolytic Treatment of Epulis;" (2) "Plantar Bunion." Dr. Semon: "Bilateral Paralysis of Crico-arytænoidei Postici Muscles" (living specimen). Dr. Barlow and Mr. Marsh: "Ovariotomy in a Child aged twelve years." Mr. Barker: "Wound of an Abnormal Obturator Artery in an Operation for Femoral Artery."

DR. MILNER FOTHERGILL'S third lecture "On Diseases of the Heart" will be delivered on Wednesday next, at 3 p.m., at the West London Hospital.

DISPENSARY MEDICAL RELIEF.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—Will you kindly inform me whether tradesmen, such as carpenters, smiths, shoemakers, &c., having plenty of work and the good wages of the present times, are entitled to dispensary relief and the services of dispensary medical officers gratuitously.

I would much like to know if this matter has been decided by the Local Government Board or any legal tribunal.

Yours, &c.,

A DISPENSARY MAN.

[The only definition of a recipient of medical relief is that he shall be a "poor" person. The L.G.B. declines to decide what the term means, and the only tribunal competent to fix a meaning in any individual case is the dispensary committee.—ED. M. P. & C.]

VIVI-SECTION AND THE BOARD OF TRINITY COLLEGE.

FROM OUR FACETIOUS CONTRIBUTOR).

OUR "silent sister" has found voice,
At least, of it a *section*,
And does not allow any choice
Upon what's a vexed question.
Humanity points out our course,
Which must take one direction,
So we must even cry, perforce,
Delphos-like, "*Vive (la) section.*"

VACANCIES.

Abbeyleix Union Workhouse.—Apothecary. Salary, £40. Election, 16th inst.
Bournemouth Cottage Hospital.—Medical Officer. Salary, £120, with furnished rooms. Applications to the Secretary before the 15th inst.
East London Hospital for Children.—Resident Medical Officer. Salary, £60 per annum, with board, &c. Applications to the Secretary on or before April 11th at the Hospital, Shadwell, E. (See Advt.)
Ennis District Lunatic Asylum.—Resident Pupil. Salary, £50, with apartments and rations. (See Advt.)
Newark Hospital.—Resident Medical Officer. Salary, £100, with board, &c. Applications to the Secretary by the 13th inst.
Paddington.—Public Analyst. Salary, £150. Information as to the duties, &c., at the Vestry Hall, Harrow Road. Election, 18th inst.
Roscommon Infirmary.—Apothecary. Salary, £60, with apartments, rations, &c. Election, 19th inst.
Royal Cornwall Dispensary.—House Surgeon and Secretary. Salary, £200, with furnished apartments. Applications to the Hon. Treasurer at the Hospital, Truro, before the 24th inst.
St. Thomas's Hospital.—Ophthalmic Surgeon. Honorary. Full information of the Secretary. Election, the 17th inst.
Tralee Union, Brosna Dispensary.—Medical Officer. Salary, £100. Election, 22nd inst.
York Dispensary.—Resident Medical Officer. Salary, £130, with furnished rooms. Applications to Mr. North, F.R.C.S., Castlegate, York.

APPOINTMENTS.

BENNETT, E. H., M.D., F.R.C.S.I., a Consulting Surgeon to St. Mark's Ophthalmic Hospital, Dublin.
BRENNAN, J. H., L.K.Q.C.P.I., L.R.C.S.I., Medical Officer and Medical Officer of Health, &c., for the Kiltormer Dispensary District of the Ballinasloe Union.
CANTLIE, J., M.D., an Assistant Surgeon to the Charing Cross Hospital.
ELLISON, Mr., M.R.C.S., Junior House Surgeon to the Birkenhead Borough Hospital.
HARVEY, C. A., M.D., C.M., a Medical Officer, &c., for the Cork Dispensary District of the Cork Union.
JEFFERSON, J. G., L.R.C.P.Ed., L.R.C.S.Ed., Medical Officer, &c., for the Aghalee Dispensary District of the Lurgan Union.
MARSH, W. A., M.R.C.S.E., Honorary Surgeon to the Newington District of the Royal South London Dispensary.
MULLINS, R. C., L.R.C.S.I., L.R.C.P.Ed., Medical Officer to the Worksop Dispensary and Hospital.
NEALE, J. E., M.R.C.S., Surgical Registrar to the Westminster Hospital.
O'NEILL, L. J., L.R.C.S.I., L.K.Q.C.P.I., Medical Officer and Medical Officer of Health, &c., for the Carney No. 2 Dispensary District of the Sligo Union.
PIDCOCK, G. D., B.A., Assistant House Surgeon to the Cumberland Infirmary, Carlisle.
REES, D. V., M.R.C.S.E., Medical Officer and Medical Officer of Health for the St. Clears and Mydrim Districts of the Carmarthen Union.
TAAFFE, M. H., L.R.C.S.I., Medical Officer and Public Vaccinator, &c., for the Ardrahan Dispensary District of the Gort Union, co. Galway.

Marriages.

FLEMING—WALLS.—April 2nd, at Belhaven Terrace, Glasgow, W. J. Fleming, M.B., to Annie, eldest daughter of W. Walls, of Glasgow.
LAMBERT—COURTENAY.—April 3rd, at All Souls', Langham Place, London, W., Walter Lambert, Captain, Royal Marine Artillery, to Frances, only daughter of Francis Burdett Courtenay, M.R.C.S. of Chandos Street, Cavendish Square.

Deaths.

APPLETON.—On March 15, at York, John Grigg Appleton, late of Luton Beds, aged 75.
EVANS.—On March 23, at Cheetham, Manchester, Thomas Evans, M.R.C.S.E., aged 25.
HOYLAND.—On April 2, at Hilden, Tunbridge, Emily Priscilla, wife of Chas. W. Hoyland, F.R.C.S., aged 69.
JOB.—On March 28, at Upper Merthyr Tydfil, John Job, L.R.C.P.L., Dowlais Ironworks, Glamorganshire, aged 27.
JONES.—On March 28, at Brentford, John William Jones, Surgeon, aged 74.
KELSON.—On April 1, at Great Marlow, Bucks, Geo. Kelson, F.R.C.S., aged 82.
MACK.—On March 31, at Colmonell, Ayrshire, John Steele Mack, L.R.C.S.Ed., aged 35.
MACLAGAN.—On April 4, at 14 Melville Street, Edinburgh, Jane, widow of David Maclagan, M.D., F.R.S., late Surgeon in Ordinary to the Queen in Scotland, aged 83.
M'LOUGHLIN.—On March 30, at Abbeyleix, Queen's County, Gordon M'Loughlin, L.A.H., aged 35.
RHIND.—On March 30, at Torquay, Samuel Rhind, L.R.C.P.Ed., aged 48.

IRISH POOR-LAW INTELLIGENCE.

THE MEDICAL EXAMINATION OF PENSIONERS.

Our attention has been directed to a correspondence in a provincial paper between a Dispensary Medical Officer and a Staff Officer of Pensioners relative to the giving of a certificate of the inability of a pensioner to present himself at the Pension Office to receive his pension. It appears that the Staff Officer requires a certificate from the man's representative as to his existence, which must be signed either by a Medical Practitioner or the clergyman of the parish in which he resides, to sign such a certificate truthfully necessarily involves a visit being made to the pensioner's residence, and we need scarcely say that there are few clergymen who would care to undergo so much labour on each quarterly pension day as to trot about through the length and breadth of his parish for the sole purpose of being able to certify that such and such a pensioner was alive on the date of his visit, but whether the clergyman's other engagements or inclination would preclude his indulging in such peregrinations or not, it rarely if ever happens that such a request would be made to him; the pension therefore of those disabled depending on the production of a certificate, it necessarily follows, the pensioner not being able to pay a fee—that the friends apply for and obtain a visiting ticket for the attendance of the Dispensary Medical Officer, who is thus compelled to make the necessary visit, and finds on arrival that the person does not require medical relief at all; when he is feelingly told that it is not to prescribe, but to write a certificate so as to enable the friends to *draw* the pension.

This abuse of the visiting ticket had almost become a recognised institution, so much so that on the day preceding pension day the unfortunate Medical Officer had a batch of scarlet runners presented to him with this object alone. After some ineffectual attempts to stop the abuse, he was at last compelled to refuse to give a certificate to every one of those whom he was called upon to visit. On the following day of meeting of the Board of Guardians the Staff Officer waited on them to know if the Medical Officer was not bound to grant such certificates when he was politely informed that it was no part of his duty, and that he was perfectly justified in demanding a fee for doing so.

The Medical Officer dealt with the Staff Officer's appearance at the Board of Guardians in a letter to a local paper, showing that it was not through any unkindly or hard-hearted feeling that he refused the certificate, simply because it was not any part of his duty, and that it was the duty of the Staff Officer either to go with or send the pension. This the Staff Officer denied, and then stated that if a proper representation were made to the Right Honourable the Secretary of State for War, a reasonable allowance would be made for such certificate. In consequence of this statement we understand that the matter has been taken up by the Irish Medical Association, and we feel quite confident that the Association will not let the matter rest until an official confirmation of the above statement is made. We would, however, suggest that a scale of fees should be made out for this sort of duty, where, for instance, a journey has to be made into the country, mileage ought to be allowed. We merely throw out this suggestion, being quite sure that the subject is in the hands of those who will not omit anything that is for the good or dignity of the profession.

THE TYRONE COUNTY INFIRMARY.

In his last report to the Governors of the Infirmary, Dr. Thompson avails himself of the opportunity to administer a much-needed warning to the supporters of the Institution, and to plead for the maintenance of County Infirmaries all over Ireland.

In the present session of Parliament a Grand Jury Bill will he introduced, which, it is supposed, will interfere most materially with the interests of the Irish County Infirmaries. We are also menaced by another bill, introduced by Mr. C. Meldon, M.P. for Kildare, the purport of which I believe to be a change in the mode of electing the governing body of the Institutions, a proposal to bring them directly under the Poor-law Board, and the appointment of Inspectors, &c.

With some of these proposals the governors would no doubt agree, for instance—bringing the Institutions more directly under the Local Government board so as to insure a proper inspection and audit of accounts. I do not, however, think it would be for the advantage of the Irish Infirmaries to place them under the control of the Local Boards of Guardians. In my opinion the present governing body of the various Irish County Infirmaries is all that could be desired, and I very much doubt if its constitution could be altered for the better.

In my last report I alluded shortly to the hospitals

attached to workhouses, and I drew your attention to the objection evinced by the respectable tenant farmers, shop assistants, servants, &c., to make use of them. I also briefly pointed out the disadvantages they labour under as compared with County Infirmaries in the scientific treatment of medical, and especially surgical, diseases. I endeavoured to point out the necessity for some central hospital in each county for the treatment of severe medical and surgical cases; and I drew attention to the irreparable loss the medical profession in this country would suffer by the general closure of County Infirmaries. Although I have adduced many arguments to prove the benefit derived from County Infirmaries, I think by far the best and strongest reason for their existence will be found in the brief summary of the work done in your own County Hospital during the past year, which may be taken as an example of similar work done in the other Irish County Infirmaries.

718 patients have received medical or surgical treatment in your Infirmary, an increase when compared with the total admissions in the preceding year of 135.

I was obliged, therefore, to refuse admission to 50 applicants, whom I considered either incurable or suitable for admission to the workhouse. 60 capital operations have been performed. 30 fractures and 2 dislocations were under treatment during the year, all of which, with three exceptions, made a good recovery. I am glad to say the mortality of the Infirmary was trifling, only 18 deaths being registered, or an average of 28.4 per 1,000, considerably smaller than the average mortality prevalent in Dublin.

POOR LAW MEDICAL RELIEF.

TO THE EDITOR OF THE IRISH TIMES.

SIR,—The article in your issue of the 7th instant on this subject presses unduly upon the dispensary medical officers, and its tone is calculated to encourage the abuse of tickets, an abuse which is officially admitted to exist (see report of Local Government Board for Ireland, 1874-75).

The article points to the proper filling and signing of tickets as an "inexorable rule," and a "mere quibble." This is to be regretted, because the ruling of the Local Government Board is decisive—"The ticket and counterpart are both to be filled up by the person authorised to issue the ticket. . . . Care should be taken in the issue of tickets accordingly;" and again, more recently —"The practice of signing blank tickets and leaving them to be afterwards filled up by a person who is not authorised to give tickets is at variance with the Medical Charities Act, and with the dispensary regulations."

It is not correct to say that "in the rural districts the members of dispensary committees, to whom the issue of red tickets is entrusted, are all respectable farmers." They are a very mixed society, in which nearly every class is represented. In each committee there are usually from fifteen to twenty members, exclusive of the wardens and relieving officer, and the average population of a dispensary district is about 5,000; so that with such facilities for procuring tickets as these figures indicate, it does not appear necessary that any ticker-issuer should neglect his business on account of the sick poor, nor that anything should prevent his taking as much care in the issuing of his tickets as in that of his cheques.

There is not much argument needed to prove that if the legal ticket-issuer himself frequently affords medical relief to unsuitable persons, his relatives, male and female, his shop assistant, or servant are much more likely to do so.

The article goes on:—"We have seldom heard of such a case" (abuse of relief by ticket) "in which the informality of the ticket was also raised." Possibly, yet cases of this kind are almost of daily occurrence in the rural districts, and the writer knows of several instances which took place not long since in Dublin. In one of these, lately brought before a board of guardians, it transpired that the ticket was not even signed by the person whose name was appended, and that the father of the child for whom it had been given was a respectable tradesman, occupying an entire house, rated at £18 yearly. The chairman of the board expressed it as his view, that "public opinion ought to be brought to bear on the matter, for the abuse was one which should not be permitted to exist."

The truth is, so long as the tickets are given by irresponsible people, who are very generally bound by local ties and obligations to be generous at the doctor's expense, so long will there be an abuse of the system, and the first step on the road to its reform is clearly to make the ticket-issuer a paid official, responsible for the proper and faithful discharge of his duty. The article makes no allusion, however, to a really "hard and fast line," a "rigid, inexorable rule," which compels the medical officer to attend at once upon a visiting ticket, no matter when or where presented, for whom given or by whom filled, provided only that the name of an authorised person be attached. Delay on the officer's part means an investigation; refusal to attend, in all likelihood, dismissal. These things being so, it is worse than useless, it is mischievous, to suggest that "while the doctor was disputing the ability of the man to pay the patient died." So far as the great majority of dispensary medical men is concerned, the "guinea fee for one journey" is a miserable myth, but it is often put forward as an excuse for having given a ticket improperly. The grievances (by no means confined to the abuse of tickets), of the dispensary medical officers of Ireland are becoming a serious question. Anything which has a depressing effect on the *status* and prospects of a large body of educated, intelligent public servants must cause injurious reaction on the general welfare. The truth of the proposition is as obvious as the truth of its converse: "that that service which is most advantageous to the public is, after all, the most advantageous for those who yield such service, whether they be regarded as individuals or as classes."

I remain, sir, yours obediently,
JOHN A. SPENCER, Member of the Council,
Irish Medical Association.

WICKLOW ASSIZES.

THE COUNTY INFIRMARY.

A proposition to abolish the County Infirmary was brought forward by Colonel Tighe. As the majority of the Grand Jury expressed their disapproval of the proposal it was not pressed, and the matter dropped.

BALLINA GUARDIANS.

FEES FOR EXAMINING PAUPER LUNATICS.

AN order on the Board, for the payment to Dr. Mahon of £2, for examining a dangerous lunatic was presented, signed by two justices.

Mr. Crean—We had an order for payment to Dr. Mahon of £2 a fortnight ago, but on that occasion it was said the lunatic lived some distance from Crossmolina, and the payment was not discussed; but this is a different case, and the same sum is awarded.

Chairman—I certainly would regulate it according to the distance travelled, and the trouble and expense the doctor is put to. There may be some circumstances in the case we are not aware of.

Mr. Crean—The last fee paid here will have the effect of raising the rate in the division 2d. in the £.

The Clerk said in the Ballina District Dr. Scott, during the last six months, had got two fees of £1 10s. and £1 1s. for examining dangerous lunatics, in the first case having had to go out to the place two or three times. At the same time Dr. Mahon had received one fee of £1 10s. and two fees of £2 each, and now this one of £2 more.

The Chairman drew up the following minute, which was approved of:—

"Approved, but to be returned for the appending of seals of the signatory justices, Vic. 38 & 39, c. 67. The Board also wish, with all respect, to hope, in such cases as that within, the justices will, in the interest of the ratepayers, assess the amount of remuneration to medical officers in proportion to the trouble and cost they may have had to incur in each individual case, two pounds being the maximum."

LIMERICK SANITARY BOARD.

LETTERS were read from the L. G. B., in which the following occurs:—

The facts disclosed in question, call for serious attention, and it is difficult to understand the utility of the course taken by the Committee in directing a further reference of the matter to Drs. Holmes and Meehan. The reports show that 102 houses in the streets are without connecting drains into the main sewer; that 128 houses out of the total number are without privies; and that 135 are without ash-pits. Of these, there are 52 let in tenements; 33 having yards and 19 having none; and access to yards where they do exist is only allowed to the lodgers. In 3 cases only 43 houses have water laid on, leaving no less than 100 in the 3 streets without a supply. The notices which were issued and served upon other persons having premises in need of sanitary improvements were, for some unexplained reason withdrawn, and to this course of action may in some measure be attributed the disorderly state of things brought under notice in Dr. Barry's report. There cannot be a question that they should act on the recommendation of their consulting sanitary officer, and cause the sanitary improvements which he indicates to be duly carried into effect with the least possible delay.

Resolved—That, inasmuch as the L. G. B. now urge us to carry out the improvements recommended by Dr. Barry—the executive sanitary officer be instructed to confer, and to take measures for having such drains and other improvements made as may be considered most urgently required.

THE DEATH OF DR. WILLIAM F. MARA, OF ATHY.

WE chronicle with regret the death of Dr. William F. Mara, medical officer of the Athy dispensary district. Dr. Mara recently contracted typhus fever in the discharge of his duties, and on the 22nd ult. his illness came to a fatal termination. The sad event has excited profound sorrow, not only among the large circle of friends to whom Dr. Mara had endeared himself by his genial manners and kindly disposition, but among those who had known him professionally. He had not practised many months in Ireland, but even during the brief period that has elapsed since he made the district around Athy the field of his professional labours, he had given many proofs of his ability.

THE GENERAL MEDICAL COUNCIL OF EDUCATION AND REGISTRATION.

SESSION 1878.

FIRST DAY.—APRIL 10, 1878.

THE General Medical Council met for the first time this year on Wednesday, April 10th, at two o'clock. The minutes of the preceding meeting having been confirmed, the new members of the Council, Drs. Fergus, Pettigrew, and Orr were introduced.

THE PRESIDENT'S ADDRESS.

The PRESIDENT then delivered the following address:

The Medical Council has this year been called together thus early in the Parliamentary Session to enable it to carry forward, and if possible to conclude for a long time to come, its deliberations on the Amendment of the Medical Acts. It may not, however, be assumed that in one sitting the Council will be able completely to fulfil its duty in this respect.

Although the business of the Council has of late increased, there is not much that demands your instant attention, except the Bills affecting the Profession of Medicine, actually before Parliament or in contemplation, together with questions arising out of them.

Since your last meeting, steps have been taken to make the Medical Register more accurate than heretofore. The volume which is now in your hands has in it several thousand corrections, besides other alterations in the typographical arrangements, and some additional prefatory matter. For these, as for other office improvements, the Council is indebted to the Registrar.

The Minutes of the Executive Committee will have informed the Council of communications from the Board of Trade relating to Weights and Measures, and from the Registrar-General on important points connected with the relation of his office to the Medical Council.

Communications concerning the removal of names from the Register, and other subjects connected therewith, will, when required, be laid before you.

Acting under your instructions, the Executive Committee made applications to the various Licensing Bodies concerning the insufficiency of General Education in many of the candidates who present themselves for professional examination. The answers from these authorities will be laid on the table. Papers written by registered practitioners have been confidentially forwarded to me as President, to show that the neglect of the practice of writing the English language, permitted by some Examining Boards, cannot be reprehended in too strong terms, if ordinary literary culture is to form an essential part of the training for a scientific profession.

The scheme for the Conjoint Examining Board in England has been industriously elaborated under the presidency of Sir James Paget. It may be permitted to one of the members of the Committee to say that the discussions among the representatives of the several Licensing Bodies have shown, when considered in connection with the recommendations of the Council, and the evidence given to it through Mr. Syme's Committee in 1868, that much remains to be done before this country can rightly claim to have settled views on the course, time, and methods indispensable for securing a sound education for the Practice of Medicine. It becomes more and more clear that the Examining Boards regulate the steps by which a student is fitted to pass an examination on a particular day. The question is whether thus we best prepare him for the practical discharge of his life-long work. This proves the great importance—nay, the necessity—of having Examining Boards composed of the highest and fittest persons for the special duty of examining, that can be induced to undertake it. Another important conclusion may be drawn—so trite indeed as to seem almost impertinent to name it—that the opportunities for learning in different hospitals and universities are at least as diverse as the mode of testing results has ever been. As regards scientific teaching, an eminent teacher (Mr. Savory) has again lately drawn public attention to the importance of organising the means for the best scientific teaching not necessarily connected with the chief place of clinical teaching, the hospital.

A recommendation just made by the Commissioners of the Universities of Scotland, that no candidate shall be admitted

to Examination in Human Anatomy or Physiology, or in any purely Medical subject, unless he has passed an examination in natural philosophy, chemistry, physiology, botany, and zoology, as constituting the second and third groups of the fifth or natural science department for the degree of M.A., will have an important bearing on the time and place necessary for scientific training preparatory to medical study, and for professional study, respectively.

Considerations of this kind will force themselves on our minds whenever we discuss the nature and extent of examination rules to be made generally binding by the authority of the Medical Council.

Documents will be laid before you from various bodies affected by the Medical Acts Amendment Bill presented to the House of Lords on March 19th.

At the close of the session of last year the Medical Council urged on the Lord President that a Bill should be brought in by the Government to amend the Medical Acts. The Lord President, acknowledging the importance of the objects which the Council presented to his view, promised his best attention to the whole matter. His Grace has fully redeemed this pledge, and, whatever be the result, deserves the warm thanks of all who are interested in the settlement of medical legislation.

Immediately after the summer recess the Lord President personally considered all the materials which he had before him for amending the Medical Acts, whether obtained from the Council or from other sources.

The Medical Council had pressed on his Grace, and through him on the Government, the importance of an early settlement of the following five subjects, viz. :—

1. The recognition of Foreign and Colonial qualifications in England,
2. The privileges of women in regard to medical qualifications,
3. The appropriation of penalties under the Medical Act,
4. To some extent the education of midwives,
5. And, indirectly, the emendation of the law affecting certificates of lunacy.

After full consideration of these several subjects, the Lord President informed me that the Government were of opinion that it might in the end be more satisfactory to the Council, as well as to the Legislature and to the country, to bring into a Bill, together with these points, certain others for which legislation had at one time or other been desired.

On all these matters the Lord President sought from me information; and I gave him such as I believed would most nearly express the opinions of the Council. But I would not take on myself to advise his Grace to omit from a Government Bill any of the subjects relating to our profession which might be regarded as of public importance, even though on some of them the Council had not expressed a definite opinion.

There is a great temptation for your President to summon the Council on every occasion of consequence, and to throw responsibility at every turn on the Executive Committee. But both are so heavy a charge to the finances—the Committee costing nearly £50 for one afternoon, the Council £400, if summoned for one day (or an average of about £165 daily for a whole session)—that the President must often be content to bear the burden which you impose upon him, feeling sure of your support where he deserves it, and always certain of your lenient judgment.

This last winter, indeed, the task was not difficult, for the Lord President seemed to have one only desire, to know how best to legislate for the medical profession in its varied relations to the body politic, and in its own complex inner organisation. Nor can it be without interest to this Council, that, looking on this body as the appointed exponent of a great section of society, he had desired in all ways to aid and support it.

The important Society of Obstetricians had pressed repeatedly on the public mind the desirability of complete legislation concerning midwives. It is, moreover, manifest, that the vexed question of the relations of the medical profession towards women, and the fitness of women to practise the whole of medicine and the whole of surgery, or any part or parts of medicine and surgery, could not be completely decided upon without a discussion on the education and organisation of the midwives of the future.

The body of Dentists—a class in the body politic of whom, when the actual suffering which they seek to prevent and to alleviate is taken into account, one must say that it is an important and useful body—urged on the attention of Parliament their claims to better organisation, depending on and justified by a higher education and fitness.

The Lord President was little disposed to neglect the numerous persons engaged in these occupations respectively—professionally occupied as they are—through the entire country, nor to sever those classes thus growing in importance, as social organisation becomes more perfect, from the medical profession and the Medical Council.

Having decided, then, to consider all outstanding questions known to affect the profession of medicine, and through it the public at large, the Lord President could hardly have left untouched the subject of examinations, which was handled in a complete and masterly way in the Bill so well known as Lord Ripon's Bill. Though the Council had not last year pressed on the Lord President's notice the subject of diminishing the number of ways by which the licences could be obtained, he knew well the anxious thought which the Council had long and often bestowed upon it; he was acquainted with the resolutions which the Council had passed with regard to Lord Ripon's Bill; and fully estimated the importance to the public of one uniform and satisfactory test of qualification for entry to the Medical Register, in each Branch of the United Kingdom.

The Lord President could not therefore but entertain the question. If a Bill was brought in either without Lord Ripon's clauses relating to examinations, or without some modification of them, it was clear that it would have to be argued in Parliament that the existing arrangements need no alteration. Could this argument be maintained? Is the Medical Council fully agreed upon it?

It is often said that the whole profession considered, when Lord Ripon's Bill was brought before Parliament, that the mode of conducting examinations by the examining bodies was the subject that most urgently called for parliamentary revision. It is not, however, necessary now to revert to the circumstances which led to the withdrawal of the Bill.

But in this the Council will assuredly be unanimous, that it is in the interest of all persons concerned—in the interests of the Public, of the Council, of Medical Teachers, and of Students—no longer to delay a final settlement of the principles on which examinations shall be conducted in England, in Scotland, and Ireland. Some evils have disappeared: some new difficulties have perhaps arisen. Education, examination—nay, even knowledge itself—have greatly altered within the last 20 years. Those who have attended the more than fifty conferences which have taken place in England, in the belief that they were discharging a great public duty, may fairly ask to be released if their labours be not shown to be material to the public interest, or if the apparent benefit in one division of the kingdom should be productive of other and unknown evils through any other division of the kingdom. It is clear that the matter cannot be decided without frank and full discussion both in this Council and in Parliament. The discussion here will be dispassionate and based upon correct estimate of the present and of the past state of the several licensing bodies and of the popular sentiment. That sentiment is certainly in favour of making it impossible that 19 separate examining and licensing boards with their varied qualities should co-exist. The public are convinced that there are dangers in the continuance of so many modes of entering the profession, and think the system of inspection offers only a cumbrous and fitful check to constant danger. There are not wanting signs that some both within and without the medical profession would prefer State-appointed examiners, or an examining board appointed by this Council, not only to the present system of many examining boards—with permissive power to combine—but would even prefer State-appointed examiners to persons appointed by the present universities and corporations in combination. It is well known that the framers of the Act of 1858 expected the permissive principle of combination, under section 19 of the Act, to be more largely adopted than it has been.

It would ill become me to use any arguments on one side or the other, inasmuch as my function is almost limited to collecting facts for your consideration. Yet I cannot but observe in this relation that it will be a grave misfortune for our generation if it be forced to the conclusion that our ancient medical institutions, hitherto self-administered, must abdicate their functions of guiding the education of our youth. And that is the risk that is run. One government might give to this Medical Council a task which the corporations decline to execute, namely, the making the National Examining Boards. Another government might assign it not to this Council, but to a single

person, who, however able, might not possess the combined judgment of the many and eminent minds brought together of necessity by a representative board.

The Lord President, as the Council is aware, has not at present elected to make the formation of a single board compulsory for each branch of the United Kingdom. It is not too much for me to say that, as his Grace hoped for discussion and for the freest expression of opinion from all who are entitled to be heard, and having referred the Bill to this Council, the question for us to consider is, whether union is expedient or requisite. The form in which the proposition is put is not perhaps of much moment for the issue. But it cannot be less acceptable to the various authorities to ask the government, after discussion, to grant more extended power for good, than to have had to protest against unnecessary interference, and uncalled for dictation for which the Council had not applied.

I cannot help noticing, with regard to those who in 1858 first undertook the working of the Medical Act, with all its conflicting interests, that while, during the 20 years that the Act has been in operation, in Ireland one licensing body alone has changed its representative, Scotland sends only one of its original members, England sends but two such members, and not a single original nominee of the Crown remains in the Council. It cannot be amiss, therefore, to take the sense of the existing Council in the most unfettered way on the state of the medical examinations in the country, in order that it may fairly face the work of the future.

It would waste the time of the Council if the details of the Bill that has been in the hands of all the members between two and three weeks were even enumerated. The aim of the Bill is, without doubt, to supply all the known deficiencies of the medical acts, and, if possible, to adjust the machinery of this Council so that it may not be distracted from its strict work, the regulation of medical education and the watchful care of a great profession, in the public interest.

The principal objects of the Bill (I quote from the Lord President's speech) "are, first, to require a person registered in the Medical Register to have both a medical and a surgical qualification; second, to allow the registration of foreign and colonial practitioners; third, to further restrict the assumption by unqualified persons of designations implying qualifications; fourth, to make further provision for the uniformity of the standard in the grant of qualification in the United Kingdom; fifth, to make provision for women similar to that intended to be made by 39 & 40 Vic., cap. 41, commonly called Mr. Russell Gurney's Act; sixth, to make provision for the examination and registration of dentists; seventh, to make provision for the examination and registration of midwives; eight, to make amendments in the Medical Act of 1858 as regards the registers, erasures from the register, the certificates of medical practitioners under the lunacy acts, the qualification of medical officers in colonial ships, and other minor matters."

It was truly added by the Lord President, that this measure "deals with a subject of great importance, but one of great complexity, and which, when legislation is proposed in respect of it, requires great consideration in numerous details. The subject is one for which there should be no hasty legislation, and I should hope that by the time the Bill comes on for a second reading, we shall have the benefit of being in possession of the views of all persons in the country who may be interested in its details, and who are competent to give advice on the matter. I hope I need not add that we shall be most ready to give an attentive consideration to all suggestions which may be offered with the object of securing a good and useful measure, and one which will be satisfactory both to the medical profession and the public at large."

Before quitting the consideration of this part of the work of the session, I beg you to excuse me if I seem in any improper way, or indeed in any sense, to be the interpreter of a measure to which the Government has given much thought, which is full of delicate and difficult questions, and which deals with great institutions and important persons.

I need not say that I have no functions in the matter except, first, to carry out as far as I can your desires, and secondly, in your absence to act to the best of my judgment on your behalf.

The grave anxiety of the Eastern Question has made it difficult to arrange the times and the mode for the introduction and the readings of the Bill in the way best calculated to carry a bill this session, and to suit the time and convenience of the Medical Council. But that way has been sought, and, I trust, attained.

Let us hope that we may come to unanimous conclusions as to the changes which may be required in the Bill, and then that it may this session become an Act with good effect.

This done, might we not hope for the consolidation of all the medical acts, with further power if necessary? Thus would be ended the first twenty years of combined effort towards harmonising the work of the time-honoured institutions which have nurtured in Great Britain the Science and Practice of Medicine. Thus would the Council go forward unfettered to accomplish further work, in aid of the great demands made, in many ways, upon a profession whose aim is so to pierce the secret of all life, that it may strengthen individual and national health, relieve all physical suffering, diminish much social evil, and soothe or avert the inevitable end.

After a short discussion as to what would be the probable course of the business of the Council,

The PRESIDENT proposed that certain documents should be taken as read.

This was overruled in the case of the communication laid on the table from the Royal College of Surgeons of London and the Royal College of Physicians of London, several members representing that they had not, as yet, had time to peruse them.

These documents were accordingly read by the Registrar.

The Memorandum of the College of Surgeons points out that by clause 3 of the Lord President's new Medical Act, its M.R.C.S., F.R.C.S., and L.M. would no longer be registrable unless accompanied by a medical qualification from some authority entitled to grant a license in medicine, and that the L.M. would apparently not be registrable at all, unless, perhaps, in certain contingencies (under paragraph 7, clause 9), as an addition to titles otherwise sufficient for registration. And, further, that if clause 14 becomes law the College will have no authority to grant even a valid surgical diploma, except in subordination, as the General Medical Council, with the sanction of the Privy Council, might have laid down. The memorandum also points out that no provision is made in the bill towards the attainment of a conjoint system of examination, in which cause they are ready to make great sacrifices with regard to the granting of this minimum qualification, and that it tends to perpetuate "the evil of nineteen uncombined and (in principle) competing bodies," and that hence "the reform most wanting in the licensing system of the United Kingdom would, perhaps, be impeded rather than promoted by the passing of the bill."

With regard to clause 23, the College observes that it throws the whole weight of dental education, examination, licensing, and registration on the shoulders of the General Medical Council, and that the College "can take no valid action, under its charter of 1859, until the General Medical Council and the Privy Council had seen fit to approve of some "scheme" proposed for the purpose. That the same spirit of extreme centralisation is shown in clause 24, which proposes that the General Medical Council shall provide a "new national institution for the examination, licensing, and registration of midwives." In this matter, while of opinion that legislation is necessary and desirable, they believe that a law would better compass those objects which would "throw the main stress of responsibility on *local* administrative authorities, with *local* professional assistance," and that the General Medical Council can hardly be utilised with advantage in this matter for more than, perhaps, some *general rules* with regard to the education and examination of midwives.

The protest from the Royal College of Physicians of London is couched in very similar language, and is directed mainly to the objections it also entertains to clauses 3, 8, 9, 14, 17.

A letter was then read from the President of the Medical Reform Committee of the British Medical Association, with regard to the legislative measures which it is the desire of the Association to support.

Dr. TURNER then gave notice that he would, on the

ensuing day, ask whether the measure mentioned in the letter was to be considered that of the British Medical Association as a body, or only of its Reform Committee.

THE CONJOINT SCHEME.—THE DEBATE.

Sir W. GULL then rose "to inquire what progress had been made in the matter of a Conjoint Scheme for a common examination in Scotland and Ireland." The speaker remarked that at the time he proposed this question he had hoped that there would have been by this time a Conjoint Scheme for England in working order. That, however, was not the case, but he still put the question in the hope that it might prove a landmark in our slow progress towards that end.

Dr. TURNER stated that a Conjoint Scheme had been in action in Scotland ever since 1859 (referring to the union of the Colleges of Surgeons and Physicians both in Edinburgh and Glasgow.)

Sir WILLIAM GULL replied that such a system was in no way analagous to the species of Conjoint Scheme to which he referred.

The Medical Act (1858) Amendment Bill was then taken as read.

Dr. HUMPHRY then gave notice of motion—

In 1870 this Council passed the following resolution, by a large majority, and after much deliberation :—

"That this Council is of opinion that a joint examining board should be formed in each of the three divisions of the kingdom, and that every person who desires to be registered under any of the qualifications recognised in Schedule (A) to the Medical Act shall be required, previously to such registration, to appear before one of these boards and be examined in all the subjects which may be deemed advisable by the Medical Council; the rights and privileges of the Universities and Corporations being in all other respects the same as at present."

The Council has subsequently sanctioned a scheme for an examining board for England made in conformity with that resolution.

The Council adheres to the principle of that resolution, and is of opinion that no medical legislation relating to examinations will be satisfactory which does not provide for the formation of an examining board in each of the three divisions of the kingdom, and direct that every person who desires to be registered under the Medical Act shall be required to appear before one of these boards, and be examined in the subjects which may be deemed necessary by the Medical Council.

Dr. Humphry then rose to explain his motion. He remarked that he had no sooner read the Act than he was stricken by surprise at the utter want of any adequate provision for the great principle that there should be one examining board for each of the three divisions of the kingdom. He wished to impress upon the Council that it had never had more important business than at present, and expressed a hope that the question might be discussed in no narrow spirit, but from the broad point of view of what were the best interests both of the profession and the public. The speaker then gave a sketch of the efforts which had been made by the Council towards the attainment of a Conjoint Examinational Scheme, from the minutes of the Council 1860 to 1870 (vol viii., page 32), when the above resolution, the result of the united efforts of Drs. Parkes and Thompson, was, after long and patient discussion, passed, and this, not by a majority composed of members from any one section of the kingdom, but by a large majority of Scotch and Irish as well as of English representatives, so that it might be considered a truly national vote. The Council went even further, recommending Government to bring in and carry through a bill to bring this principle into effect. With such a measure the Council had hitherto identified itself. Acting on the recommendations of the Council, the English medical authorities set to work and framed a series of regulations with a view to the carrying into effect this principle. The result of their labours is that a scheme has been nearly completed. The English authorities had been much taunted as to their slowness in carrying out these projects, but he would remind such cavillers that such delay was the almost necessary adjunct of the development of any great and important question. He (Dr. Humphry) remarked that his double connection with the College of Surgeons, and with the growing medical school of the University of Cambridge, gave him great opportunities for gauging the state of professional opinion in England, and he found the apprehension general that this great work would not be completed for the want of a similar organisation in the other divisions of the kingdom, and that when they taunt England for her slowness they should remember that that delay was in reality due to themselves. The speaker then pointed out the public spirit which had been shown by the various English licensing bodies sacrificing their individual interests to the attainment of an uniform minimum qualifying standard. He exhorted the Council to remember that all this had been done in conformity with their wishes, and not now to stultify itself by leaving them in the lurch; that it was everywhere felt to be an anomaly that any and every one of these nineteeen various bodies should have the power to confer a licence to practice all branches of our art. The system of supervision of examinations was of course an attempt to bring about some degree of uniformity, but in point of fact, the Council had always shrunk from the difficulty and cost of carrying this out in an effective manner. These many bodies were thus laid open to the imputation of a downward competition, and the very possibility of such an imputation ought not to be tolerated. That there was some ground for such an imputation was shown by the wide difference of the proportion of candidates rejected at the different examining bodies, and in support of this adduced the instances of the L.R.C.S.Ed. and L.R.C.S.I. examinations, where 6 out of 66 and 4 out of 89 only were respectively rejected.

The speaker was here interrupted by Dr. WOOD, who pointed out that this did not fairly represent the proportion of rejections by R.C.S.Ed., as most candidates for the L.R.C.S. alone were men who had already passed the severer examination for graduation at the Edinburgh University, and that the combined L.R.C.S. and L.R.C.P. showed a proportion of rejections as high as that of the English licensing bodies, and added that he hoped the reporters would take this down, as such a statement might seriously affect the prestige of the Scotch licensing bodies.

Mr. MACNAMARA also explained that the 4 out of 89 was exceptional, as was evidenced by the fact that at the *second* examination for the L.R.C.S.I., 33 out of 99 candidates were rejected.

Dr. HUMPHRY replied that all he wished to point out was, that there ought to be no possibility of any question of the sort arising. What, then, were the objections to this principle? These, he understood, proceeded mainly from Scotland. What all their objections were he did not quite know, but he had heard some of them. First, that it would not after all secure absolute uniformity, as there would still be three examining boards. To this it might be replied that the variety would at any rate be more than sixfold, and the Council will no longer have the task of supervising nineteen examining bodies, but the more practicable business of visiting three only. Again, the combination of a number of bodies in a conjoint scheme would prevent any tendency of the mere "L.S.D." interests of any body producing a downward competition. Again, it is with obvious want of consistency said, You will get too much uniformity. This also is not true, but there is professed in Scotland an apprehension that it would bring the level of their university degrees to that of the minimum qualification. But the English universities have shown no such fear, taking it as certain, and in fact, stipulating that their own degrees should be left untouched. Such a course as this is equally open to the Scotch universities. The only objection "on principle" the speaker knew of was, that such an uniform

qualifying standard would lead to a dead level of mediocrity. But this objection was based on misapprehension, because this so-called evil will go no further than institute an uniform minimum qualification, as the universities and other bodies will still have the power of making their degrees as severe as they please. And this will, in fact, leave the universities freer than before, as they will no longer be held back from a high standard by the reflection that the candidates' daily bread may depend on their dictum. It has been stated that the Scotch licensing bodies *cannot* acquiesce in such a scheme, because the students would have to travel from all parts to Edinburgh for examination. Is *cannot* a word to be used in Scotland? *Will not* is a word much more likely to be used by Scotchmen, and to be carried through by Scotch strength of purpose. But those who make this objection seem to forget that such an arrangement already exists without inconvenience in England; that, in fact, there are large teaching bodies at Manchester, Birmingham, Bristol, &c., whose candidates are obliged to repair to London for examination. It is said that the interests of these licensing bodies would be affected, but the members of the Council are not here as representatives of licensing bodies, but as an organisation to carry out for the country the provisions of the 1858 Act. By the introduction of the Earl of Ripon's Bill, which contained a clause for enforcing uniformity of examination, the Government showed its appreciation of the principle involved. That Bill, however, did not pass, not on account of that clause, but on account of a side issue, and we have now to deal with the present Bill. He (Dr. Humphry) confessed he was astounded to find this principle quite out of the Act. He told the Council that it had been squeezed out by the strong grasp of Scotland. He had no objection to Scotland seeking for as much influence in the Legislature as they could, but he did not consider it the right way; the duty of England and of the Council was to carry through the principle which they had so long advocated. They had substituted a sort of double action by requiring a double qualification. The objections entertained to this were shown by the protestations they had received from the R.C.S.E. and R.C.P.L. It recognises the necessity of combination, but does not provide for it. That if clause 14 pass, there is no single body which will be able to grant degrees, except under rules made by this Council and approved by the Privy Council. Nay, that it went further, giving the Privy Council power to alter those rules without let or hindrance, and placing all authorities entirely under the hand of the Privy Council. Surely, there could be no question between such a sacrifice of all independence as this, and the smaller sacrifice, he might rather say, continuance of independence, in the form of a representative examining body, subject only to the control of this Council. He only wished that the Scotch members had been present at the Conferences recently held at the R.C.S.E., they would have then seen the value of the representatives of many bodies meeting together to further an important issue. He would have them bear in mind that each successive act of the Legislature had been to press its foot more firmly on the one thing they had worth fighting for—the independence of the profession and the right of self-government. Surely, the persons best qualified to regulate medical education were those who had themselves gone through it. Let them remember that there was a daily growing public demand for the establishment of the principle he advocated. They would be mere politicians, if they seized on this demand while it was still young and pliable, to bend and train it after their own pattern, and to blend it with their own ancient institutions. Let then the Council not stultify itself, but stand to its colours in this question, as on its issue it might almost be said that the Council must stand or fall.

Dr. Wood then rose. After regretting that the task of opening the opposition should devolve on him, he first adverted to the charge of inconsistency and of retrogression, and stated that in his opinion, this was not the case. That had the system been a good one, the difficulties in Scotland would not have arisen, and that Scotland opposed the scheme, because after thoroughly scanning the question, they had come to the conclusion that the scheme was impracticable. That Dr. Humphry appeared to take it for granted that a Conjoint Scheme must necessarily be a good one, but he would endeavour to show that such was not the case. They had now been working twenty years under a Medical Act. Could it be said that no advance had been made during that time? Was it necessary for them now to take a new point of departure? He supported the present bill, because it was a mild measure, and not such a revolutionary proceeding as that advocated by Dr. Humphry. That before the Medical Act of 1858, there was pressing need for medical reform, he admitted, as then the separate licensing bodies were under no control whatever. That then, as now, there were fragmentary qualifications, and that this was an undoubted defect in the Act of 1858. But that bill contained a permissive clause, allowing and affording facilities for the combination of authorities. Now where had this clause been taken advantage of? Only in Scotland, abused Scotland. Before the Act of 1858, preliminary education was nowhere insisted on.

Mr. Macnamara refused to admit this, with regard to Ireland, where he said preliminary education was as good a hundred years ago as it now is.

Dr. Wood replied that he *ought* to admit they had improved, if he did not. The speaker then reviewed the difficulties that had to be surmounted before the Act of 1858 could be passed, and the Medical Council established on its present basis. That Act had now been in force twenty years. What had been done by the Medical Council during that period? If they took the *ipse dixit* of the editorial "we" of the medical papers, it would be replied that the Medical Council were a set of useless fellows who met together to spend money, talk a lot, and do little. He hoped to show, however, that it was quite otherwise. The speaker then proceeded to enumerate at some length the improvements in medical education, examination, and legislation, that had been effected by the General Medical Council, and adverted to the good that had been done by the system of visitation of examinations, and made an eloquent allusion to the distinguished men who had sat on the Council. He then remarked on the advantage that had been gained in Scotland by the voluntary combination of examining bodies, these in accordance with the powers granted by the Act of 1858, and regretted that similar combinations had not been formed in England and Ireland. He confessed he felt some sympathy with the latter part of Dr. Humphry's speech, but he did not entertain so much apprehension with regard to the power of the Privy Council, because he thought those powers would be mainly exercised in protecting the interests of the corporations, rather than in coercing them. Why the English corporations did not combine, he knew not; but the fact remained, that until 1870 they made no steps in the matter. In 1870, England appeared roused to an energy as fiery as her former apathy was extreme. They went in not for a judicious partial combination, but for an entirely Conjoint Scheme, and wanted to force Ireland and Scotland to do the same. Scotland refused, not because she could not, or would not, but because she did not approve of it. That England even evidently looked on the Conjoint Scheme as but an experiment, was shown by the clause which allowed of the withdrawal of any corporation from it at the end of five years, but that, if they got the present bill modelled after the pattern of Lord Ripon's, they would have no power of withdrawal, even should the matter turn out as bad a job as he was inclined to expect. That the wish for uniformity would not be secured by it, as the number of candidates was so great that for any one board to examine them would be a job to which the labours of Hercules were a "small joke." This would necessitate the breaking up of the board into sections, and so sacrifice their much-desired uniformity. In order to secure uniformity, the board would either have to be peri-

patetic, or the candidates would have to come from all parts to some central examining board. Another objection which he had, was that each body would part with the power of examining the candidates who would bear their name, and that he feared that the association of the licensing bodies would either have the tendency of bringing down the university standard to the level of the minimum qualifying standard, or that the universities would raise the latter above the reach of the average student. What he feared they would get, would be an absolute dead level of mediocrity. He indignantly repelled the insinuation that he was advocating any individual interest, but he stood there with the object of improving the profession. He alluded to a recent conversation he had had with Sir Robert Christison, in which that veteran medical reformer had urged him to impress on the Council the danger of plunging into an experiment, the end of which could not be foreseen. If the machinery of medical education were rusty, let them oil it, if the regulating wheel wanted weight, let them strengthen it, but let them not tear the old machine to pieces to build up a new one, of whose working properties they are entirely ignorant.

Sir DOMINIC CORRIGAN then made a short but very humorous speech, in which he stated that he supported the system of double registration because he thought it all that was wanted. Prof. Humphry wanted Ireland to follow the example of England with regard to a Conjoint Scheme. England had been twenty years about that scheme, and had not yet completed it. He hardly thought that an example worthy of imitation. He thought that the Council would rather stultify itself by adhering to its old policy than by changing it for a better. He thought that the conjoint scheme would put an end to all emulation, as why should a man take higher degrees when he found himself equally qualified for all Government posts by his minimum qualification; and pointed out that graduations of qualifications existed everywhere.

Prof. ROLLESTON then spoke in favour of the motion, and ridiculed the difficulties that the Scotch and Irish representatives appeared to see in a central examining board. Was the distance between Edinburgh, Glasgow, and Aberdeen so immense? Had they no railroads or book post in Scotland? He argued that by the Conjoint Scheme they would get all the advantages of centralisation without its evils. If they did not take care they would have all power stripped from their hands by the establishment of a *State examination*, as had been done in other countries.

The Council then adjourned.

SECOND DAY.—DEBATE ON THE CONJOINT SCHEME—(*Continued.*)

ON the resumption of the sitting on April 11, the minutes of the preceding meeting were read and confirmed.

Dr. ROLLESTON continued his observations. He was glad that he now held Lord Ripon's Bill in his hand, as it showed the danger of the profession being crushed by the steam-roller of Government interference. He felt a great respect for Dr. Christison, but he could not see that any argument worthy of the name had as yet been advanced by the opponents of the Conjoint Scheme. He remarked that those who were good at excuses were seldom good at practical matters, and that this was shown by the objection that one board would not be able to deal with the number of candidates. Could this be said to be a valid objection in the face of the fact of the immense number of candidates examined by the University of London. He hoped that Dr. Storrar would rise and state whether that body found much difficulty in examining a large number of candidates.

Mr. TEALE remarked that he felt sure that they had come to a very critical point of the history of the Medical Council. He thought he should not be overstating the case in saying that there was a widely-spread feeling that the Medical Council had not done all that it might in the cause of medical education. For the last few years the Council had gone on making recommendations which might or might not be attended to, and he thought that this led to a want of earnestness in their deliberations. He could not say that he shared the apprehensions of Prof. Wood with regard to conjoint examinations. He could not see that there was a likelihood of any dead level, or of any too great raising or depression of the standard of the minimum qualifications, as there would always be the Council to supervise and prevent this. He remarked that it appeared to him that the present number of examining bodies was a great waste of power, and that unless the Council supported a Conjoint Scheme they would soon be wiped away as useless, to make way for a State examination.

Dr. STORRAR said that the University of London found no difficulty in examining large numbers of candidates, and instanced, in addition, that the College of Surgeons examined without difficulty 500 candidates at its primary, and 300 at its second examination. Dr. Wood had stated that this was a new point of departure. He went back to the Bill of 1858, instead of forwards, and he (Dr. Storrar) was very grateful that he did not take back his history of the medical profession to the stone age. He would now give his version of what happened in 1858. In 1856 the necessity for reform having become obvious, the matter was brought into the House of Commons, which was none too well informed on the subject. This was referred to a Select Committee, who proposed what was, in fact, a *State examination*. The Corporations resisted this stoutly. The Parliament was very anxious to get the matter settled as soon as possible, and hence Mr. Walpole brought in a Bill which was, in fact, a compromise, sweeping away the old local jurisdictions, and instituting a register and a council to supervise the actions of the separate examining boards, but throwing aside the general examining board. We have been working on this Bill for the last twenty years, but on account of its defects, much has been wanting, and he agreed with Dr. Rolleston that unless we now move on some strong Government will step in and take the matter in their own hands. He was much astonished to hear Dr. Wood boast that Scotland had been the first to establish a Conjoint Board, and pointed out that this was in reality not a lessening of the number of examinations, but of making nine examinations instead of seven. It would be of course a ridiculous statement, and an undeserved censure on the Council, to say that no improvement had been made in the profession under the auspices of the Council. But surely he would not maintain that the present state of things was perfection. He now approached a delicate subject, that of the excellence of the examinations of Scotland. He had had no personal experience of those examinations, but he knew many young men who had passed through those qualifications, and he found that their experience did not lead him to think the state of things so excellent as Dr. A. Wood appeared to think. One word with regard to the body which he himself represented. As soon as a Conjoint Scheme had been fairly propounded, they had stepped out and offered to associate themselves with it, and when it should be brought into action they would not be found behind, even at some sacrifice of money and of independence.

Dr. HALDANE remarked that the ideal Conjoint Scheme was always prepossessing, but on attempting to carry it out great difficulties were found even in England. In Scotland even greater difficulty was found towards the attainment of this object, on account of the much larger percentage of candidates who there take university degrees. He did not think that the combinations existing in Scotland had been such a failure as Dr. Storrar appeared to think, and the figures showed that these combinations had had the effect of greatly lessening the number of single qualifications granted. He looked upon universities and corporations as distinct and separate bodies, and did not think that it was desirable that they should be combined with a conjoint establishment. He looked upon university degrees as higher honours than those granted by the corporations, and thought it to be regretted that university

degrees should be at all looked upon as mere qualifications to practise. He thought it a pity to interfere with the present state of things. He did not share the fears of Prof. Rolleston with regard to a State examination ; in fact he would much prefer one to a conjoint scheme, and thought it would be much more satisfactory both to the profession and the public.

Dr. QUAIN then said he wished to make a few observations as one who had from the first been associated with the attempt to establish a Conjoint Scheme. At the time of Mr. Walpole's bill it was understood that that bill was entirely tentative. He wanted to know how it was that candidates were, every day, crossing the Tweed, and coming back with a qualification at a less expense both in money and brain power. He alluded to the petition, signed by 9,000 medical men, from Dr. Bell Fletcher, praying for some kind of Conjoint Scheme. Supposing that a *State examination* was established, who would go to the halls and corporations when they had got such a qualification as that of a *State examination*. They would practically all be swept away. The difficulties in the way of a Conjoint Scheme were not so great as was imagined ; all the difference was that instead of candidates being examined here, there, and everywhere, they would combine the examination at one place.

Dr. TURNER objected to the form they were taking in discussing an abstract resolution, as disrespectful to the Lord President's Bill. He considered it an attempt to force the hand of the Council by committing itself to an abstract resolution before considering the bill which had been sent down for consideration. He considered that Dr. Humphry's motion required more elucidation. It leaves it quite open as to whether there is meant a Conjoint Scheme, or something quite outside our system, it might even be a *State examination*. Dr. Humphry especially stated that he never in the course of his speech mentioned a Conjoint Scheme. What did he mean ?

Sir JAMES PAGET here said, as seconder of the speech, that Dr. Humphry, he believed, considered anything, even a *State examination*, was better than a continuance of the present state of things.

Dr. TURNER continued his observations, by alluding to the so-called anomaly of nineteen licensing bodies. No one at the present day would care to establish such a number of bodies for one purpose. But one should not look upon it entirely from the light of the present day, but from the historical point of view. They were ancient bodies, but progressive bodies also, and there was no evi- to prove that they had in any way betrayed their trust. He wished to contrast the evidence of Dr. Storrar's unknown students with that of their own visitors ; it was in the power of the Council to stop the action of those who were not up to the mark. He did not, therefore, attach much importance to Dr. Humphry's objection with regard to the anomalous nature of the state of things. He did not consider that absolute uniformity was good, but apart from that, he did not consider that such uniformity was attainable. A standard of examination was a mental conception, and could not be cut and shaped like a fluid or solid measure. Each examiner would have his own standard, and this even would vary in the same man from such trifling causes even as a fit of indigestion. To secure such absolute uniformity, it would be necessary to have all candidates examined by one examiner always in the same state of health. He feared that such centralisation wouldbecome a great encouragement for cramming, because there being but one examining board, its peculiarities would become all the better known. Such uniformity, however, would be not secured, as there were in the Conjoint scheme eight examiners in each subject, and hence there would be as great variety as there was in the old system. He pointed to the report of the Royal Commission on the Universities of Scotland, which stated that in its opinion the Scottish universities should not be made mere places of preparation for some central examination, and that such a course would put an end to all independence of thought and training. He considered that it would interfere with the solid kind of education which it was so important for all candidates for university degrees to have. He thought that he was not in error in stating that the Conjoint Scheme interposed another examination between the candidate and the object he had in view. The necessity of passing such an examination would lead them to concentrate their energies on the preparation for its lower standard, instead of the higher education required for the university degree. A former speaker had remarked that the adoption of a Conjoint Scheme would make no difference in the examinations as the same men would be examiners as before, all the available examining talent being at present in use in the various examining boards. He, however, doubted that such would be the case. The total number of examiners required would be considerably less, and hence more time would be required to be given by each examiner to the business of examining, a greater amount of time in fact than a man in active practice would be able to afford, and the result would be that the post of examiner would be only sought by inferior men. He would have it noticed that the case of the Scottish and English universities was different, the latter having practically no schools attached to them. The former, on the other hand, had under their tuition an immense number of students, and he thought that they owed it to these young men to defend their interests in the independence of the Scottish universities. The course of study and education at the Scottish universities was in every sense a complete one, and they felt, not to mince matters, the English had no right to force their young men to pass an examination of a kind they considered in every way inferior to their own, and in addition to subject them to a pecuniary fine in the form of an examination. Whatever might be said of the merits of the case, there was a momentary side to the question which must be faced. A large portion of the revenues of the Scottish universities was derived from the examination fees. These fees did not go into the pockets of the examiners, but were returned to the student by being applied to the improvement of their means of education ; and this justified the Scottish universities in opposing any scheme which would have the effect of lessening the number of candidates for their degrees.

Dr. AQUILLA SMITH felt convinced that the establishment of such an examination would materially lessen the number of candidates for the higher examinations. He, too, considered that it would be not only injurious, but derogatory to the universities, to force them to combine with the Corporations. He hoped that the Council would now pass to the consideration of the Lord President's Bill by dismissing the motion before them as soon as possible.

Mr. MACNAMARA said that he did not consider that the time of the Council had been wasted in this discussion, because if they accepted the motion, it would be tantamount to the rejection of the Lord President's Bill. He felt sure that the adoption of a Conjoint Scheme would have a deteriorating tendency on the profession, whereas the present Bill necessitates each candidate having a separate examination in medicine and surgery, and he thought this would obviate the tendency any single examination must have of letting pass a candidate weak in medicine, because he was specially good in surgery. He begged to retract any impression he might have given yesterday of depreciating the Scotch degrees. In years gone by, when he was a grinder, he used to charge £20 for preparations for the Irish degrees, £15 for the English, and £10 for the Scotch qualifications. He was now no longer a grinder, but he had inquired of gentlemen engaged at present in that honourable calling, and they had replied, "troth, we make them all pay just the same." He hoped that the Council would adopt the Lord President's Bill, and reject Prof. Humphry's motion. He considered that the Bill contained very many important points. He objected to some clauses, but on the whole he approved of the measure.

Sir W. GULL deprecated further discussion on the motion, as every man's mind was already made up as to how he was going to vote. He would, therefore, be as brief as possible. Dr. Wood had stated that the difficulties in the way of estab-

lishing a Conjoint System in Scotland might be overcome. Dr. Turner, on the other hand, said it was impossible. The gentlemen from the other side of the Tweed had given many reasons—he would not dignify them by the name of arguments—why Scotland would not have the Conjoint Scheme. They had kept their real reason—the pecuniary one—back to the last. All the reasons they had advanced were either political or pecuniary, and none were based on the broad principle of the public weal. It could not be denied that the Scotch University Degree was nothing more than a licensing examination.

Dr. TURNER entirely objected, and dissented from such a statement.

Sir W. GULL—Dr. Turner might object, but it was nevertheless the truth. There was a wide difference between the Scotch Universities and the London University; the standard of the former was a minimum standard, that of the latter a maximum standard. How otherwise could it be the case, that so large a proportion of Scotch candidates took a University degree, while so small a percentage of English students attained the degree of the University of London. It was folly to attempt to deny that the present bill would not have been more stringent but for the political reason of the objections raised by the Scotch medical authorities. It was pleasant to hear the speeches made yesterday by the gentlemen from Scotland. The Council was resolved into a Society for mutual congratulation. It was delightful to hear how smoothly everything was working, and how much the Council had done for the profession, and how well it had done its duty. But how was the Council to efficiently perform its duty of supervision of examinations, while those examinations remained so numerous? The Council had nothing to do with politics, and pecuniary matters were equally outside its scope. Its duty was to strengthen the hands of the Government by clearly stating what was best both for the profession and the public, and he did not think that any disinterested person would maintain that the Conjoint Scheme was not superior to the present bill. The question of the fees was decidedly a difficulty, but the proper course was to try to surmount it. The difficulties lay mainly in Scotland; Ireland, as Sir Dominic Corrigan had told them, was perfect. He hoped that his separate interests would not be allowed to obscure the main question at issue.

Dr. PITMAN pointed out that Drs. Wood and Haldane, on the one hand, stated that a Conjoint Examination existed in Scotland, and on the other, that a Conjoint Scheme was impossible. What was the meaning of this, but that the Scotch and English ideas of a Conjoint Scheme were different, and that the so-called Scotch Conjoined Scheme left open the possibility of fragmentary qualifications? The Lord President's Bill prevented this, but did it go about this in the best way? He considered it very objectionable that the Scotch Universities were at the same time educational and examining bodies. He considered it most objectionable that any man should examine his own pupils, and this was entirely impossible in the English Conjoint Scheme. He was satisfied that the day must come when the bodies would either be forced to combine, or be swept away to make room for some new examining board, and he thought that the Council should make an effort to get restored to the bill the principle which had been, by extraneous pressure, excluded from it.

The debate was then adjourned until the next day. During the remaining time some unimportant formal business was transacted.

THIRD DAY—DEBATE ON THE CONJOINT SCHEME—(*Continued.*)

The minutes of the preceding meeting having been read and confirmed, the Council passed to the adjourned consideration of Dr. Humphry's motion.

Sir DOMINIC CORRIGAN asked, What is the state of the English Conjoint Scheme?

The PRESIDENT replied that he had asked Sir James Paget as president of the committee for the Conjoint Scheme to reply.

SIR JAMES PAGET said that the Conjoint Scheme was in the same condition as on the preceding session of the Council; that the scheme after being confirmed by the Council, had been referred to the several English educational bodies. That a committee of reference had been appointed to carry out matters of detail with regard to regulations for examination and education. That their labours are nearly completed, and it was possible that the Conjoint Scheme might be in full working order by October next. Whether it would or not, evidently depended to a great extent on the decision of the Council, and on the fate of the present Medical Act.

Mr. SIMON then rose to speak on Dr. Humphry's motion. Many speakers on the opposition had, he said, stigmatised the motion an abstract, obscure as a snake in the grass, as a trap to catch the unwary, &c., the unwary greenhorns being their astute selves. If the motion were abstract, he knew not what was concrete. If obscure to them, it was clear as daylight to him; if they thought they had scotched the snake, they had not killed it. Mr. Macnamara had said that the motion broke the back of the bill. He could not see that the bill had any back bone, to him it appeared[moluscus, not to say jelly fish. He could not see that the bill as it stood involved any principle at all. After all, what was the object of the Medical Acts, and of the institution of the Council, but to secure to the public that none but properly qualified persons should be allowed to practice as medical men? The present state of things did not satisfactorily guarantee this, and he objected to such a mere permissive measure as the present bill, because he thought it threw back rather than advanced the cause. He thought that persuasion was more the province of the churchman than of the statesman. That the present Council had done much towards the improvement of medical education he would not deny. But the unsatisfactory nature of the present state of things was shown, by the little attention that was bestowed even to the most clearly expressed *dicta* of the Council—was shown by the retention of the system of each authority still having its own examination in preliminary education in spite of the recommendations of the Council to the contrary. He could not see that the argument that not even single examiners could keep up a uniform standard of examination, was worthy of a philosophical mind. Then as to the question of the difficulty of a central examination. Was there any need of peripatetic examiners, had they not railways by which the candidates might come to them?

Dr. TURNER—It was not a question of railways, but of expense to the candidate.

Mr. SIMON—How great, then, must be the inducements which lead English students to undergo so much fatigue and expense in that they go all the way to Edinburgh in order to come back with high-sounding titles—(laughter)—titles which are often used for unworthy purposes.

Dr. TURNER demanded an explanation of this expression, as he considered it a very serious charge against the Scotch Universities.

Mr. SIMON explained that he referred to the custom of English candidates taking a minimum qualification in Scotland, and being allowed on their return to style themselves as doctor.

Sir DOMINIC CORRIGAN said that he himself, as a Scotch graduate, was quite satisfied with Mr. Simon's explanation, as he had cleared the Scotch Universities from his imputations by confining them to Englishmen.

Mr. SIMON could not see why the difficulty of combining corporations and universities should be in any way derogatory to the latter, as combinations might easily be made, in which the University concerned itself mainly with science, and the corporations with medicine and surgery. He hoped that the motion would be carried, in order that the back-bone, so much desired by Mr. Macnamara, might be inserted into the new Medical Bill.

Sir J. PAGET said, before speaking on the motion itself, he should like to say a few words on the Bill to which it referred, as he feared lest an impression should get abroad that the Council entirely disapproved of the Bill, and this he did not think ought to be the case. On this account he was glad that in the form of the motion, the point of the Bill which was most open to objection, was being debated first. In many points the Bill was no doubt good. It was a general complaint on the part of the universities that they were obliged to pass persons who were not up to the standard they should like, because their examinations were also qualifying examinations. The London University was the only one that withstood this tendency. If, then, these examinations were made mere qualifying examinations, they convicted all lower qualifications of being below what ought to be the minimum. Sir Dominic Corrigan had asked him what was the state of the English Conjoint Scheme? and he had replied, briefly, that reply was that the English Conjoint Scheme was practically ready to be put into work. The Scotch had said they should like to see the result of the experiment in England. He had no doubt but that the Scheme would succeed if the experiment

were fairly tried, but how was it to be fairly tried if the Scotch and Irish did not try the experiment at the same time. The public had been gradually educated to consider that a single uniform examinational standard was necessary. If they accepted the Conjoint Scheme, this would be done by their own will, in their own way, and by their own rules. If they did not, they would have to do it against their will, and after other people's methods and rules. He did not consider the present Bill a mild measure in that if it passed, no authority would be able to grant any degree except under the rules made by the Council, and approved by the Privy Council. Could any measure be said to be a mild one with such a sting in it as that. If no Conjoint Scheme were adopted they were sure to drift sooner or later into a State Examination. There were two ways of arranging such an examination, by either placing it after or before the candidate had obtained his diploma. What could be more objectionable than subjecting candidates to a minimum examination after they obtained their degrees. It would be equal to implying that in spite of the letters after their names, they could not be trusted to practise on the public. To have the examination before allowing men to go in for their diplomas, was not so objectionable. The present Bill was equivalent to a statement from Government, that Conjoint Schemes were impossible. He therefore pitied those who allowed the Bill to pass through unmodified, when in the future they should find the result which must necessarily arise from it.

Dr. FERGUS said that he had not from the first made up his mind as to how he should vote. He had expected they would have at once proceeded to discuss the Bill clause by clause, and that the present motion appeared an attempt to shunt the Bill from discussion.

The PRESIDENT replied that the Executive Committee had considered the matter, and had decided that the consideration of the motion was the best method of considering the Bill. The President then said that he should on this occasion exercised his privilege of voting, because he considered that it was not in the interests of medical education that nineteen separate bodies, each having the right of licensing, should co-exist. He then called upon Dr. Humphry for his reply.

Dr. HUMPHRY disclaimed any intention of shunting the Bill, but said that his object was to make an attempt to get restored to the Bill the principle which had been excluded from it by the advice of the gentlemen from the North of Tweed. Dr. Turner had said that uniformity was impossible. Of course absolute uniformity was as impossible in examinations as among individuals, but such uniformity as would secure a good standard, and such as the public had a right to demand, was quite practicable and possible. The sole object of this resolution was to induce the several corporations to combine in all three divisions of the kingdom; that the corporations should combine in each division to make such a combination as should be most suitable to their own requirements. That they know their own wants far better than we do, than the Council can, or the Privy Council can. Let us, therefore, retain the freedom of self-government. The sole object of his motion was not to shunt the Bill, but to unify and preserve the liberties of the corporations.

The Council then divided, 14 voting in favour of Dr. Humphry's motion, and 10 against it.

Majority.—The President, Dr. Pitman, Sir James Paget, Mr. Bradford, Dr. Rolleston, Dr. Humphry, Dr. Pyle, Dr. Storrar, Dr. Leet, Dr. Quain, Sir William Gull, Mr. Simon, Mr. Teale, Dr. Hudson.

Minority.—Dr. Haldane, Dr. Andrew Wood, Dr. Scott Orr, Mr. Turner, Dr. Pettigrew, Dr. Aquilla Smith, Mr. Macnamara, Dr. Arjohn, Sir Dominic Corrigan, Dr. Fergus.

A FEW days since, a dealer, at Salford, was summoned for selling butterine as butter. The magistrate who tried the case came to the extraordinary conclusion that because no man could expect to buy genuine butter at 10d. per lb., therefore, a grocer who sells an inspector so-called butter at that price, is not guilty of fraud. The logic is almost beneath contempt. To carry such an absurdity further, it would be useless to go to a magistrate who is paid only half the stipend of another, because justice could not be got at the price.

HYSTERICAL CONTRACTION OF THE IRIS AND OF THE CILIARY MUSCLE.

By DR. GALEZOWSKI.

Translated by ARCHIBALD H. JACOB, M.D., F.R.C.S.,
Formerly Ophthalmic and Aural Surgeon to the City of Dublin Hospital, and the Dublin Eye and Ear Infirmary.

THE more one studies hysterical affections, the more one becomes convinced that they present a wide and extensive field for investigation. Thanks to the researches of M. Charcot on this subject, the history of hysteria is now enriched by certain data, up to the present time either unknown or else little known. This eminent professor has shown us, among other cases, and that more clearly than has been done by anyone before him, that it is, sometimes the general sensibility which is affected, sometimes special senses suffer from more or less grave alterations, and finally, that hysterical patients are sometimes seen suffering from contractions in different parts of the organism. The lesion of the general sensibility shows itself either by hemianæsthesia or analgesia, either partial, or total. Anesthesia of special senses is characterised by derangements of vision, of taste, of hearing, and of smell. Derangements of vision are characterised in a marked manner by hysterical diathesis. They are resumed in the following symptoms:—

Hysterical amblyopia. This is generally monocular, and corresponds to the side affected by hemianæsthesia. This amblyopia is very characteristic, as we have been the first to demonstrate. Besides the marked diminution of central acuteness of vision, there exists a sensible and concentric contraction of the peripheric field of vision, as well as complete dischromatopia or achromatopia. According to M. Charcot, hysterical amblyopia of one eye is nearly always accompanied by a contraction, though less marked, of the field of vision on the other side.

But amblyopia is not the only derangement of vision which exhibits itself in hysteria. We have often observed in this affection, contractions of different muscles of the eye, among others of the orbicularis, or in external or internal recti of the eye-ball. The contraction may, in thoroughly exceptional cases, attack the iris and the accommodating muscles, and consequently bring about notable modifications in the nature of the sight. Under the influence of this contraction, a permanent and durable tension of the accommodating muscle will be produced, which will conceal either partially or totally the normal refraction.

The observation given further on is one of the most interesting of its kind. The contraction of the accommodating muscle, occurring in the case of a hysterical woman, at the same time as other muscular contractions, has brought about on the one hand myosis of both eyes, as complete as possible, scarcely permitting the light to reach the depth of the eye, while on the other hand, this patient who suffers from hypermetropia was the subject of amyopia of 0·75 dioptrics which only disappeared temporarily under the influence of atropia.

Observation.—Hysterical contraction of the iris, and of the accommodating muscle.

Madame Emma de Freschel, 38 years of age, came to my surgery, number 26 Rue Dauphine, on the 9th of October, 1877. She is married, and the mother of a daughter 20 years of age. Since the time of her confinement, she has been subject to nervous attacks, brought on by the most trifling occurrences. These attacks are characterised by the sensation of a ball rising in the throat, and causing such a sensation of smothering that the patient, unable to bear the pain, tears her breast with her nails. During these attacks, which are always accompanied by alternating fits of laughing and crying, the patient heard and saw nothing; she became completely unconscious.

These attacks usually appeared after menstruation. Soon the patient feels her extremities becoming numb, and her joints stiffening, the lower part of the legs became swelled, and at length a general feeling of discomfort, which slightly affected her health.

Five or six years ago, the fits of laughing and of crying which accompanied these attacks ceased. Since this time, the patient has not become unconscious, but often suffers from faintness and giddiness, especially while digestion is going on. Since this epoch, that is to say, since about six years ago, she has felt her sight failing.

At the same time she began to suffer from shooting pains in the left leg, which she could only ease by the application of cold water. These accidents became further complicated by incontinence of urine; every night during these attacks she passed urine in her bed. These accidents ceased, however, on the 25th of last August. On this day, the patient having just finished a meal, wished to get up from the table, and found her left leg had suddenly become benumbed, and that she could not move it in the slightest degree. Even at the present moment this lady limps considerably with the left leg, of which, however, thanks to electricity, which has been successfully applied during five weeks, she has partially regained the power of movement. The foot is turned slightly outwards, and a permanent contraction of the flexor muscles exists.

The general sensibility is enfeebled in the left half of the body. The limits may be easily fixed, and correspond perfectly to the median line of the body; on the left side of the body, a pin may be inserted with impunity to a depth of two millimetres without causing the least sensation. The left ala is devoid of sensibility, while the right ala feels the prick of the pin. It is the same for the cornea; the finger may be passed over the left cornea without causing the patient to wink. There is nothing abnormal in the external parts of the eye. No kind of paralysis of the motor muscles has been observed. The iris of both eyes is contracted, and myosis so well marked, that the depth of the eye cannot be observed. The acuteness of vision, and the peripheric field of vision are in their normal condition, and the chromatic faculty is preserved.

On examining her on the 21st of last October, we observed that her pupils presented a diameter of 2 millimetres; the patient was the subject of a myopia of 5·75 dioptrics, but after having instilled a drop of atropia, we obtained a dilation of 6 millimetres and a marked degree of hypermetropia, for it was only with a convex glass of 1·75 dioptrics that she could see at a distance. The patient has been on several occasions subjected to metallotherapic treatment. Dr. Burcq has, in the presence of M. Charcot, applied several metals either to the left leg or to the orbits of the eyes. Silver alone has influenced the sensibility of the patient, but no metal has, up to the present time, caused the spasms of the accommodating muscle to cease, and the short-sightedness induced by contraction still continues.

Spasmodic myopia, induced by hysterical accidents, is an occurrence unique of its kind; and we do not think that it has been observed by others in any case before this one. This affection is not only rare in the hysterical diathesis, but is quite as much so in other diseases, constitutional or not, and we only know of some isolated cases in ophthalmology.

De Graefe (*a*) has only twice observed a tonic spasm of the accommodating muscle, and he considered it as a reflex neuralgia, supervening in consequence of the lesions of the sensitive nerves. We, on our part, have observed acquired myopia with permanent contraction of the accommodating muscle, in the case of a young woman who had tried to poison herself with a strong dose of opium. (*b*) Lastly, we have observed in the case of a patient suffering from ataxic syphilis, and who had been obligingly sent to us by Professor Lasègue, well pronounced myosis, accompanied by acquired myopia.

The contraction of the pupil is not rare; it has been even frequently observed in locomotor ataxy, as has been very clearly demonstrated by Romberg, Duchenne (de Boulogne), and by M. Charcot. Its presence in diseases of the heart (Eulenburg, Guttmann, Giovanni) has also been observed; but in these cases, the contraction is limited to the radiating fibres of the iris, and the accommodating muscle was not attacked. In the case of another patient, on the contrary, the hysterical contraction of the pupil had given place to an accidental myopia, resulting precisely from a spasm of the accommodating muscle. It is probable that at some future day, a means may be found of modifying this ocular contraction, or that it will modify itself spontaneously after an attack, but, it is certain that up to the present time, all means, internal or local have been without effect.

NOTES ON MIDWIFERY.

Manual Evolution successfully performed in Arm Presentation.

By THOMAS BEAMISH, L.K.Q.C.P.I., L.R.C.S.I.,
Passage West, co. Cork.

HAVING seen a communication from Dr. Tuckey, of Castletownroche, in the MEDICAL PRESS AND CIRCULAR, headed "Spontaneous Evolution successfully Initiated," and reference being made to me (as I am the medical gentleman he speaks of), I beg to state that I did perform the operation so long as four years ago, though not exactly in the way Dr. Tuckey describes, and I purposed calling the operation "Manual Evolution" in contradistinction to "Spontaneous Evolution." I was glad to see Dr. Tuckey's case in print, as it makes me more confident in the opinions I had formed. I will now, as briefly as possible, describe the details of the operation, as performed by myself.

April, 1874.—I was called to M. C., æt. 35, in her seventh confinement. She had, eight hours previously, given birth to a small twin child, about four pounds' weight. I was told by the nurse that the waters of the second child had broken four hours before I saw her. On making an examination, I found the arm in the vagina, the uterus was firmly contracted on the body of the child, labour pains were very strong and frequent (the woman's own words were, that she would burst if not relieved). I at once dismissed the idea from my mind of introducing my hand into the womb to turn, as rupture of the organ or other injuries would undoubtedly have been the consequence, and considering that Nature had often effected delivery under similar circumstances, by what is termed spontaneous evolution, I did not see why I should not be able to imitate that process, and guide it to a safe termination.

Having emptied the bladder, I took the arm of the child in my right hand and drew it well down, bringing it slightly forward under the arch of the pubes, when I found I could bring the shoulder beyond the vulva, about half an inch, I could, in fact, see portion of the chest (I should say about the outer third of the clavicle), I then passed the fingers of the left hand into the vagina and over the chest of the child, and was able to hook my fingers over the last true rib, which I pressed, or rather drew down the wall of the chest being easily compressed and shortened, so to speak; I then placed the blunt hook over the rib, which gave me more power and released my fingers, then taking the hook in my left hand, I steadied the child in that position, and placing the fingers of my right hand in the axilla of the child, I pressed the body upwards, outwards, and backwards, at the same time drawing the hook (which was fixed over the rib), down-

wards and forwards, when to my great satisfaction, I felt and saw the shoulder and arm of the child recede, and a breech presentation perfected; the delivery was then conducted in the ordinary way. The woman recovered without a bad symptom, and has been a mother once or twice since. The operation was not a very difficult one, and was performed without violence, no excessive force being used. I am satisfied it will succeed in most cases, and do away with the necessity of introducing the hand into the womb, which I consider a dangerous proceeding under such circumstances. I at the time laid it down as my future rule of practice in such cases, and most certainly I shall endeavour to carry it out in every case of the kind that comes before me, and I trust that others of more experience will give it a fair trial, and judge for themselves. When writing this case out I forgot to state that before completing the operation I could touch the hip of the child with my finger placed in the vagina. I have to thank Dr. Tuckey for having referred to me in his paper, and also the other medical gentleman who was kind enough to mention the case to him. Another circumstance I forgot to mention was the death of the child, of which I satisfied myself before I commenced to deliver. The woman was on her right side the whole time, with her hips well over the edge of the bed.

The Medical Press and Circular

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, APRIL 17, 1878.

THE PRESIDENT'S ADDRESS TO THE GENERAL MEDICAL COUNCIL.

THERE is nothing very noteworthy in the address which Dr. Acland delivered before the Medical Council, and, therefore, we shall make our remarks as brief as possible, the more so, as by the time these columns are in the hands of our readers the Council will have entered fully into the discussion of matters which claim a more serious attention.

The present session of the Council opens at a very critical period of medical politics and medical legislation; and just as Parliament met this year a month earlier than usual on account of the momentous questions it had to discuss, so has the Medical Council already been sitting for some days on account of the pressure that is now from all sides put upon it to accelerate such a medical reform as shall be satisfactory to the public and to the profession. The new Medical Bill will be read for the second time on the 15th inst. It has, however, given so much dissatisfaction to all who are interested in the subject of medical reform, and has been so sharply criticised by the medical press, that most of us are anxious to know what the Council will have to say on the matter. If that great representative body has for years been subject to animadversions that have been by no means complimentary in respect of either its opinions, or its transactions, or the influence it has had on the advancement of medical education, it will now be more than ever put upon its trial, and its decisions with regard to the Medical Bill, the Conjoint Scheme, and other important questions, will either justify or silence the clamour that has long been raised against its limited powers, and even its very existence. There is, however, nothing in Dr. Acland's speech to indicate the gravity of those questions in the final settlement of which the Council is now called upon to take an important part, and in the settlement of which the Council has the opportunity of showing the profession and the public that their interests will always receive the first consideration of the Council, and that no vested interests of any kind will be allowed to stand in the way of effecting such a wholesome reform as shall be satisfactory to all parties, both within and without the profession. The address is altogether a remarkably calm and matter-of-fact statement of the questions calling for the consideration of the Council, without any attempt to impress upon its members the necessity of coming to such resolutions as shall command the respectful attention of the Legislature and the universal assent of the medical profession. The projected amendment of the Medical Act and the formation of Conjoint Boards very naturally engaged the attention of the President of the Council; but we cannot help remarking that in his observations on these subjects, Dr. Acland showed a certain leaning towards the great medical corporations which are, it is to be regretted, too exclusively represented by the Council. In alluding to the possibility of the State taking the subject of medical examinations into their own hands, the President says, "it will be a grave misfortune for our generation if it be forced to the conclusion that our ancient medical institutions, hitherto self-administered, must abdicate their functions of guiding the education of our youth." Again, he remarks that the "Lord President of the Privy Council has not elected to make the formation of a single board compulsory for each branch of the United Kingdom. It is not too much for me to say that, as his Grace hoped for discussion and for the freest expression of opinion from all who are entitled to be heard, and having referred the Bill to this Council, the question for us to consider is whether union is expedient or requisite. The form in which the proposition is put is not perhaps of

much moment for the issue. But it cannot be less acceptable to the various authorities to ask the Government, after discussion, to grant more extended power for good, than to have had to protest against unnecessary interference, and uncalled-for dictation for which the Council had not applied."

It is, no doubt, somewhat flattering to the Medical Council that so much deference should be paid to their decisions, and that the very permissiveness (if we may use the expression) of the Medical Bill now before Parliament—the most objectionable feature in it—should have been owing to the desire of the Lord President to be guided by the opinions of the Council. At the same time, as the influence of the Council, and the results of its deliberations, and indeed its very constitution, have not been such as to inspire so much confidence as was desirable, many will regret that the Medical Bill is not of a more compulsory character, and that, moreover, the President of the Council regards the permissive character of the Bill with a certain amount of complacency which it is to be hoped will not be shared by the body over which he presides. That, however, the Council is probably alive to the necessity of a single Board being compulsory for each division of the United Kingdom, is shown by the resolution which on the very first day of its sitting was moved by Dr. Humphry, and seconded by Sir James Paget, namely, "That the Council adheres to the principle of the resolution passed by it in 1870, and is of opinion that no medical legislation relating to examinations will be satisfactory which does not provide for the formation of an Examining Board in each of the three divisions of the kingdom, and direct that every person who desires to be registered under the Medical Act shall be required to appear before one of these Boards and be examined in the subjects which may be deemed necessary by the Medical Council."

It has been doubted whether it should be within the province of the Medical Council to superintend the examination and registration of midwives and dentists, but from Dr. Acland's speech we may infer that, in his opinion, the Council should not flinch from adding to its other onerous duties the more questionable one of legislating for a class of practitioners that might, in the opinion of many, be easily dealt with in other ways. "It is," he says, "manifest that the vexed question of the relations of the medical profession towards women, and the fitness of women to practise the whole of medicine and the whole of surgery, or any part or parts of medicine and surgery, could not be completely decided upon without a discussion on the education and organisation of the midwives of the future."

There is one point in the President's address to which we would, in conclusion, especially draw the attention of those members of the Council who may be inclined to waste their valuable time in needless discussion, or in remarks that are totally irrelevant of the questions under consideration. "There is," said Dr. Acland, "a great temptation for your President to summon the Council on every occasion of consequence, and to throw responsibility at every turn on the Executive Committee. But both are so heavy a charge to the finances—the Committee costing nearly £50 for one afternoon, the Council £400 if summoned for one day—that the President must often be content to bear the burden which you impose upon him, feeling sure of your support where he deserves it, and always certain of your lenient judgment." The costliness of the Council has often made its censors wish that its deliberations were more fruitful of results; but, judging from the discussions that have this session already taken place, it bids fair to redeem the character it has had for being a rather imperfect as well as a costly Council of Medical Education.

THE CONJOINT SCHEME AND THE GENERAL MEDICAL COUNCIL.

THE deliberations of the General Medical Council are, perhaps, now attracting more general attention than at any previous period of its existence. The whole profession has been long anxiously waiting for the opinions and decisions of the Council with respect to questions which have for years agitated the minds of medical men, and to which a final answer seemed at last likely to be given. A proposed Bill to amend the Medical Act of 1858 is now passing through the House of Lords, and the Lord President of the Privy Council has requested the Medical Council to inform His Grace, the Duke of Richmond, of any observations it may have to offer in regard to the provisions of the Bill. Two of the most influential English corporations, the Royal College of Physicians and the Royal College of Surgeons, have represented to the Council their great dissatisfaction with the Bill; while the medical press generally, and the great body of medical practitioners have justly condemned many of its provisions. Moreover, a scheme for a Conjoint Board of Examiners for this division of the Kingdom, has at last been completed, the actual establishment and success of which depends upon the course the Council thinks proper to take in the matter, as well as upon the fate of the Bill now before Parliament. Lastly, the lay press has not ignored the importance of the questions now under the consideration of the Council and the Legislature, and the leading journal of public opinion has more than once drawn the attention of its readers to a subject in which they cannot fail to feel some interest.

Such are the reasons which invest the present session of the General Medical Council with more than usual importance, and which should have called forth from it an unanimity of opinion, in order that its voice might be heard, and its opinions carry more weight, in the Council of the State. And what has been the decision of the Council with respect more particularly to one important principle of Medical Reform which has been for years contended for by all those who, untrammelled by prejudice and vested interests, have had at heart the interests of the public and the progress of medical education? The important resolution that there should be, in the opinion of the Council, a Conjoint Board for each division of the United Kingdom, has certainly been carried. But how has it been carried? By the small majority of four. We have the English College of Physicians and the English College of Surgeons, both representing to the Council their extreme regret and disappointment that the Bill altogether fails to provide for that compulsory establishment of Conjoint Examining Boards for each division of the United Kingdom, for which both of these

colleges have been labouring and co-operating with other English authorities for many years, and for which they both, especially the College of Surgeons, have been ever ready to sacrifice their own individual interests and independence of action. "Far from encouraging," says the College of Physicians, "the English authorities to bring into operation the scheme which, after long and unremitting efforts and overcoming innumerable difficulties, they had completed and were prepared to make trial of, this Bill would compel them to abandon the scheme, and all hope of reaping any fruit from their labours." We have the President and Vice-Presidents of the College of Surgeons reminding the Council that if the Bill becomes law it could hardly fail to be deemed an expression of indifference on the part of the Legislature to that which the largest and weightiest consent of skilled authority has long recognised to be the chief evil of the present system; the evil of nineteen and (in principle) competing examining boards with the privilege allowed to each separate authority to grant registrable titles, which shall be valid throughout the British Empire. We have had, moreover, a petition signed by 9,000 medical practitioners, as well as the whole press, both lay and medical, in favour of making a far more radical change than that now contemplated. Yet, in the face of all these urgent and *ex cathedrâ* representations, we find that, at the last moment, a large proportion of the General Medical Council have voted, not only against making the Conjoint Scheme compulsory for the three divisions of the United Kingdom, but, to speak the truth, against the very principle of Conjoint Schemes in any shape.

It is unnecessary to repeat the very forcible arguments that have from almost all quarters been urged in favour of Conjoint Boards. Our readers must be by this time pretty familiar with them; and most of these arguments have been recapitulated in the able speeches of Dr. Quain, Sir Wm. Gull, Dr. Storrar, Mr. Simon, and one or two other members of the Council. But what arguments, it will be asked, have been advanced on the other side, what arguments sufficiently strong to induce ten of the twenty-four members of which the Council is composed to oppose a scheme which has, in this country, been all but unanimously accepted? We regret to say they are of the flimsiest character, so few in number, and so feeble that it is evident that the judgment of these obstructive members of the Council has been much warped by prejudice, and by a too great deference to old customs and associations. As Dr. Rolleston said, no argument worthy of the name has as yet been advanced by the opponents of the Conjoint Scheme. One of Dr. Wood's strongest arguments was, that the present state of things was all that could be desired. Very great progress had been made in the advancement of medical education and examinations. The Medical Council had, in spite of what its detractors might say to the contrary, accomplished much. The Scotch diplomas were all that could be desired, and it was false to allege that the Scotch bodies allured students from different parts of the kingdom by the lowness of their standards. If, then, such progress had been made, what need was there for any great measure of legislation? None. Then the scheme would not work, and it would not establish the uniformity in the examinations which was aimed at. How, moreover, would it be possible for a Conjoint Board to find time to examine the large number of candidates that would appear before it? Nor were vested interests forgotten by this great champion of the Scotch corporations. Dr. Wood was surprised that the English bodies should agree to the proposed scheme because it robbed them of their *raison d'ètre*, and took from them the right of examining independently their own men. They would be parting with their identity, their autonomy, and individuality. Another argument was that a Conjoint Board Scheme would tend to lower the standard of education, and that it would bring the qualifications down to one dead level. The former of these objections is certainly a very ingenious one on the part of those Scotch and Irish bodies who have never, except on compulsion, done anything to raise the standard of professional education, and with respect to the "dead level," it would be better to bring the qualifications down to a dead level, provided it were a good one, than to put up with the inequalities that now exist among the nineteen examining boards. Dr. Turner's reasons for voting against the Conjoint Scheme were still more puerile, and were certainly not worthy of his usually well-balanced mind. He took a sort of *laudator temporis acti* view of the question, and said that it should be regarded from the historical point of view. "They (the corporations) were ancient bodies, and there was nothing to prove that they had in any way betrayed their trust." As for an uniformity in the examinations, he did not think that it was attainable. Each examiner would have his own standard, and this would vary in the same way from such trifling causes as a fit of indigestion. To secure such uniformity it would be necessary to have all candidates examined by one examiner always in the same state of health!

Such were the sophisms by which (with two exceptions) the delegates from the Scotch and Irish bodies sought to justify the repugnance they had to any kind of Conjoint Board, and the attempt they had been making to "squeeze," as Dr. Humphry said, the Conjoint Examination out of the Bill. We need scarcely say it was a comparatively easy task to refute these arguments. It was not difficult to show that the examinations of some of the Scotch examining bodies were of too low a standard, and that, as Dr. Quain well put it, candidates were crossing the Tweed every day, and coming back with qualifications at a less expense, both to money and brain power. Indeed, it is a matter of common observation at Apothecaries' Hall, that men who have been previously rejected by that examining body, frequently return to it after having obtained one of the Scotch diplomas or licenses. As for the Conjoint Scheme lowering the standard of medical education, it would rather tend in the opposite direction. The objection, said Dr. Humphry, was based on misapprehension, because this so-called evil will go no further than instituting an uniform minimum qualification, as the universities and other bodies will still have the power of making their degrees as severe as they please. We may add that there is nothing in the principle of the Conjoint Scheme to prevent the examiners making the standard of examination even much higher than it is at present; and for reasons we gave on former occasion, so far from lowering the standard, the new system might even tend the other

way, and, if there was no other Conjoint Board in the United Kingdom, it might through the higher standard of its examination, be the means of driving students to those examining bodies where they could obtain a license on easier terms. Nor was it less absurd to talk of the difficulties in the way of examining a large number of candidates. It was surprising to hear a physician of Dr. Wood's standing, urging such an argument against the Conjoint Scheme; an argument which was sufficiently answered when Dr. Storrar said that the University of London found no difficulty in examining large numbers of candidates, and instanced in addition that the College of Surgeons examined without difficulty 500 candidates at its primary, and 300 at its second examination.

In conclusion, we must confess to now having very little hopes of seeing a Conjoint Board established in England, still less of seeing one in each division of the United Kingdom. It is evident that the fact of the resolution above referred, being carried by only a small majority of the Council will be an inducement to the Government to press upon the legislature the Bill in its present shape, or at all events, that clause of it which deals with the subject of Conjoint Boards. In that case, both the College of Physicians and the College of Surgeons, would probably, as they have threatened, withdraw from the scheme altogether, and the scheme itself would necessarily fall to the ground. This would certainly be a deplorable event, the more deplorable, because the means by which the establishment of Conjoint Boards had been frustrated, would be a very serious reflection upon the present constitution of the Medical Council. For it will be seen that the large minority of the Council which voted against the Conjoint Scheme, consisted entirely of members representing the several Scotch and Irish Corporations, and it follows that they could never have exercised such a preponderating, or at least, powerful influence in their own Council or in Parliament, if the Council had not been so exclusively representative of the different Corporations and Examining Bodies, but had also among its members men who, to the exclusion of all other interests, represented that great body of practitioners, which along with the public, has the most interest in the establishment of a Conjoint System of Examination.

THE IRISH LUNACY INQUIRY COMMISSION.

Our readers who are interested in lunacy in Ireland will be pleased to learn that a Commission is now sitting at the Four Courts at Dublin for the purpose of inquiring into the wants of the existing system for pauper lunatics in Ireland. The Commission is composed of Major Trench, Mr. Andrew Doyle, and Mr. Sharman Crawford and the Secretary is Mr. H. A. Robinson, son of Mr. Henry Robinson, formerly Poor-law Inspector, now Under Secretary. The Commission is, in fact, the same which was appointed for the purpose of considering the propriety of Union Amalgamation. By a warrant from His Excellency the Lord Lieutenant the scope of the inquiry was extended not long since to the following purposes—viz.: "to inquire into and investigate and report upon the provisions at present made and existing in Ireland for the care, relief, and treatment of the poor who are lunatic, or idiotic, or imbecile in mind, or otherwise suffering from mental disease, and whether it would be expedient, proper, and advisable to make other provision for the care, relief, and treatment of such poor, and, if so, in what manner and by what means such additional or other provision should be made."

The Commission addressed, on the 28th of February last, a communication to the resident medical superintendents of district asylums, in which they submitted the following queries :—

I.—*Admission.*

a. Are the rules and regulations, as laid down by order in Council for admission of patients into the asylum, in all cases strictly adhered to?

b. Do you consider the present mode of admission to be in any respect, and, if so, in what respect, defective?

c. Are you of opinion that any change, and, if so, what change, is desirable in the present form or mode of admission?

d. Can you furnish any cases, if so, be good enough to do so, in illustration of your opinions?

II.—*Discharge.*

a. Are the rules and regulations, as laid down by "Order in Council" for the discharge of patients from the asylum, in all cases strictly adhered to?

b. Can you suggest any improvement in the present mode of discharging patients?

III.—*Inspection and Supervision.*

With a view to efficient administration in the asylum, and to affording protection against improper treatment or detention of inmates, are you of opinion that the present system of visiting and inspecting can be improved, or that any change or modification in the existing "rules" can be made with advantage?

IV.—*Intermediate Asylums.*

If "intermediate asylums" for classes indicated below as A. and B. can be established, how many of each class could be removed from your district asylum to such intermediate asylums?

Class A. Incurable, but quiet, orderly, and harmless, and not dirty habits or epileptic :—		*Class* B. Incurables, and requiring especial care and supervision :—	
Females.	*Males.*	*Females.*	*Males.*

With a view to deciding upon a unanimous response to this circular, a number of the Resident Medical Superintendents held a meeting at the Limerick Junction. At this meeting the proceedings were private, but we understand that the following recommendations were the result.

1. That assistant resident medical superintendents should be appointed in every asylum.
2. That the duties of visiting physicians should be more clearly defined.
3. That the existing arrangements in reference to matrons in asylums should be altered.

The two first and most important of these recommendations point directly to a further development of the policy of abolishing the Visiting Physician, or at least, reducing him to a nonentity, which policy has been long and persistently pursued by the Inspectors, and by the Residents themselves. The effort to get rid of any supervision of the asylum or interference in its management by persons outside its walls is not a thing of to-day. To effect this purpose—to erect an

imperium within the walls of the asylum—to exclude the Board of Governors from anything but a nominal authority in its management, and to take from the Visiting Physicians the right to see or hear anything which does not seem to the R.M.S. convenient — to give to the latter officer a complete control over the treatment of the lunatics and the affairs of the institution, subject only to the occasional morning visit of an Inspector; such has been the policy followed up for more than twenty years by the Inspector's office. Throughout that long period we have declared ourselves the enemy of that policy—of any or every policy which would raise lunatic asylums above the control of watchful eyes and independent voices. We have repeatedly pointed out the extreme danger of entrusting so great powers to any one official who is but half controlled by a department which cannot see for itself, and which has shown itself wilfully blind to the abuses arising from such a system. We speak of abuses because we know that "it is human to err," and it is physically impossible that institutions thus managed shall be free of them, and we cannot forget the occasion in which a lunatic was killed by a cold bath in the Limerick Asylum, nor erase from our memory the effort made by the inquiring Inspector on that occasion to hush up the affair and throw his official protection over the Resident Superintendent, who was afterwards dismissed.

As long as an appeal against this state of things lay only to the Inspector's office or to Parliament it was obviously hopeless to attempt a reform, and it is for this reason that we rejoice that the opportunity has arisen to discuss the question before an independent tribunal. The Commission has, as we have said, consulted with the responsible officers within the asylum. Well and good! But would it not be well to take counsel also from those who are not interested in maintaining the *status quo*, but only in protecting the lunatic and securing the efficiency of the institution? Would it not be desirable to obtain the evidence of Boards of Governors and Visiting Physicians? Would not Lord Monteagle's views be worth having? Above all, would it not be well to rid the lunatic asylums of Ireland of the cloud of suspicion as to their management with which the policy heretofore pursued must necessarily overshadow them; and would not this be best done by encouraging the fullest vigilance and freedom of speech on the part of all and every person whose duty it may be to see and to report.

Notes on Current Topics.

The Army Medical Service and the Irish Students.

The week before last we printed the letter which was addressed by the War Secretary to the Irish Schools, in reference to the continued abstention of students from entering the Army Medical Service; and we stated that the Council of the Irish College of Surgeons had taken steps to ascertain, by ballot papers, the views of the Army Medical Officers on the subject.

Having received and collected a great number of replies to their inquiries, the Committee appointed by the Council arrived at a report, which, in the form of the following letter to the Secretary for War, has been adopted by the College.

Royal College of Surgeons in Ireland,
Dublin, April 11th, 1878.

Sir,—I am directed by the President and Council of the Royal College of Surgeons in Ireland, in reply to your letter of the 21st ult., $\frac{7609}{632}$, requesting that they would "favour the Right Hon. the Secretary of State for War unreservedly with their opinion as to the specific causes which produce the existing difficulty in obtaining candidates for the Army Medical Department," to state that the President and Council have had the subjects therein referred to under their anxious consideration for a lengthened period, as shown in their memorial presented by deputation to the Right Hon. the Secretary of State for War upon the 3rd of June, 1875.

Since the receipt of your communication the President and Council have taken further steps for the purpose of ascertaining accurately the causes which render the Army Medical Service now so unpopular, which produce the dissatisfaction that exists amongst those serving in it, and which deter eligible candidates from joining. These are :—

Firstly—The short service scheme now in existence.

Secondly—The Abolition of the Regimental system.

Thirdly—The frequent changes in Warrants, after they have been published under Royal authority with Her Majesty's signature, and on faith of the permanency of which Warrants, medical officers have accepted. This has produced an utter want of confidence in, and distrust of the service.

Fourthly—The differences which are made between combatant and medical officers in regard to ordinary and sick leave.

Fifthly—The almost absolute refusal to medical officers of the privilege to exchange.

Sixthly—The virtual withdrawal of forage allowance from those by rank entitled to it.

Seventhly—The quarters allotted to medical officers in barracks being almost invariably regimental, whilst they, as departmental officers, are supposed to be entitled to departmental quarters.

Eighthly—The discomfort caused to medical officers by want of a soldier servant, whilst the sum allowed in lieu thereof is incapable of providing a civilian.

Ninthly—The length of time (five-and-twenty years) before the medical officers can claim a right to retire from the service on adequate pension.

Lastly—The Roster, as now kept, which has been withdrawn from public inspection, so that no officer can tell how he stands in regard to foreign service; whereas formerly this document was exposed in the waiting-room at Whitehall Yard for each medical officer's specific information.

These are the points which deter candidates from coming forward, and the President and Council feel assured that, until ameliorated, entrance into the Army Medical Service will be avoided by the desirable class of students.

The President and Council, in conclusion, deem it right to impress upon the consideration of the Right Hon. the Secretary of State for War the fact that, at the present time, so many varied and lucrative outlets in the Civil Service present themselves for the acceptance of the junior members of the profession, that it becomes the more imperative to improve the condition of army and navy medical officers, so as to enable the naval and military services to compete on favourable terms with the civil for the obtaining of the best and most highly educated students.

I have the honour to be, Sir,
Your obedient servant,
J. Stannus Hughes, Secretary to Council.

To Ralph Thompson, Esq., C.B.,
Assistant Under-Secretary of State,
War Office, London.

This reply cannot but be said to be reasonable and temperate, and it comes from the body which is, of all others capable of forming a reliable judgment, and if it does not receive close attention from the authorities, it will be evident that the War Office has not learned wisdom from adversity.

Even if the Unification Scheme be irrevocable, it will

be open to the Secretary for War to remove almost all of these causes of complaint without serious outlay of money or detriment to the public service; and we earnestly trust that at length, the wisdom of doing so will be appreciated.

The Dental Practitioners' Bill.

It may be interesting to the qualified surgeons who practise dentistry to know that Sir John Lubbock has kindly made way for the counter-dentists beside them in the "Dental Register" by moving to strike out the words "either separately or in conjunction with the practice of medicine or surgery," from the clause of his Bill which defines the class of practitioners who are to be registered. This act of the father of the Bill is in deference to the orders of the druggists, whose views on the subject we find expressed at an indignation meeting reported in their own journal.

Mr. Barclay said the Bill, if passed in its present form, would be a serious matter to many chemists. He regarded the Bill as one more attempt to curtail the privileges or rather, he should say, the rights, of the trade, and he would suggest that it be opposed *in toto*.

Mr. Arblaster contended that not only should chemists and druggists in business at the present time be permitted to practise dentistry in accordance with an ancient custom of the trade, but that any Bill that passed into law should reserve to the rising generation of chemists and druggists the right to add the practice of dentistry to their business, if they were disposed to do so.

Mr. Churchill said the Bill would necessitate a person leaving his business for two or three years to attend courses of lectures at the hospitals.

Mr. Arblaster said there were many chemists who styled themselves dentists, and it would be a serious matter for them to be compelled to give up a title many would have held for years, and their business would probably suffer in consequence.

Messrs. Cross, Delves, and Jervis said they regarded several clauses of the Bill as hostile to the interests of the trade.

Mr. Hampson advocated such modification as would entitle any chemist and druggist in business at the present time, who so desired, to be registered as a dentist.

The demands of the surgeons being now conceded, it remains for the qualified dentists to fight their own battle, and we confess to a feeling of astonishment when we observe the readiness with which surgeon-dentists—Fellows of the Colleges of Surgeons and Licentiates in Dental Surgery—fall into rank with the oilman in the next street. If they see no impropriety in doing so, it is not for us to teach them, but we cannot help saying that—in the public interest—it is an intolerable proposition that persons as ignorant of scientific dentistry as a carpenter or an engine-driver, should be recognised by the State as competent to practise the surgery of the teeth and jaws.

Unqualified Assistants in Dublin.

General practitioners and their assistants, in the sense in which they are so styled in England, are, as most of our readers know, very scarce commodities in Dublin; and the unacquaintance of the Irish public with that peculiar system of medical practice has given occasion for a considerable degree of effervescence in the Irish metropolis. One of the very few English-style general practitioners in Dublin employed an unqualified assistant, who naturally represented himself as an emporium of medical skill, talent, and experience; but not proving to be altogether as brilliant as was expected, he was dismissed. Having appealed to the law for redress, he was answered by the general practitioner with the plea that he was ridiculously ignorant and incompetent, and had made many mistakes.

The worthy Lord Mayor thereupon said he should like to know the mode in which those compounding departments of the profession were carried out; whether those young gentlemen had passed qualifying examinations, and whether they had received a diploma. He always understood that young gentlemen engaged in mixing medicines should pass through an examination, and get a certificate from the proper authorities. As a public servant, he should like to know whether the prescriptions sent into medical establishments were compounded by gentlemen who had obtained a proper certificate or authority, and whether there was any check on those young gentlemen. He was surprised that no means had been adopted to protect the public from having their medicines improperly compounded; and as far as he was personally concerned, such a state of things would put him on his guard in future.

These reasonably indignant utterances of his lordship evolved a newspaper correspondence, prominent in which was a letter of the Apothecaries' Hall, vaguely apologetic for the existence of unqualified dispensers under their very nose.

It will hardly sooth the indignation or allay the surprise of the Lord Mayor and the Dublin public, to learn from us that the employment of young men, to whom the practice of medicine is a dim vision, is one of the commonest of occurrences; that in England a considerable proportion of the doctoring amongst the working classes is done by assistants who are employed *because* they have had no regular education and possess no qualification, and, therefore, cannot enter into rivalry with their masters—that there is nothing unusual in the doctoring of large and populous districts in the manufacturing counties, by three or four such unlicensed assistants who are in charge of separate establishments, and supposed to be under the ownership of one general practitioner—that it is a practice for some general practitioners who work in this line to sign certificates respecting the causes of death of persons whom they have never seen alive; and that, in fact, law and custom allows the life and death of thousands of persons to be entrusted to unqualified assistants who have learned most of what they know upon the vile bodies of their master's clients, and who pursue their experiments upon such bodies under the cloke of their master's qualification.

The chief magistrate of Dublin is horrified at the notion of death-doses being dispensed to his fellow citizens by ignorant and careless boys. What would he say if he realised the vision of such young gentlemen not only making up the medicine but prescribing it themselves?

The vacancy in the list of Vice-presidents of the Medical Society of the Dublin College of Physicians caused by the decease of Dr. Stokes, F.R.S., has been filled by the election of Dr. J. T. Banks, physician to the Richmond Hospital.

The Small-pox in Dublin.

THE latest of the Irish Registrar-General's Reports shows serious progress in the small-pox epidemic. In the week to which it refers (ending April 6), 10 deaths from variola were registered, the numbers for the last nine consecutive weeks being 2, 6, 2, 7, 6, 7, 12, 7, and 10. On the 6th inst. there were in Cork-street Fever Hospital alone 106 cases, of whom 35 had been admitted within the week. Meanwhile, the South Dublin Guardians have been exercising their wits in the endeavour to do nothing, hoping that the epidemic would pass over without the necessity for an expenditure of money, and so far was this policy pursued that the Local Government Board was obliged to inform them that unless they set to work they would be dismissed at once, and three commissioners appointed in their place. The Public Health Committee of the Corporation is—*more suo*,—making excuses, trying to conceal the small-pox epidemic from the knowledge of the public, and to make it appear that the horrible mortality of the city is all the result of the east wind or the poverty of the people.

Our attention has been called to a matter in connection with the epidemic which will need earnest consideration. It is stated that patients are being discharged from the hospital as convalescents, but with the variolous scabs still thick upon them, carrying the disease, of course, straight home to their families, and the responsible officer of the hospital in question meets all remonstrances by saying, that the business of his institution is to cure, and it is no affair of his where the patient goes, or what he brings home with him. This is a shallow and heartless excuse, and we fail to see why a curative institution should be free of the obligation under which every individual is, to prevent the spread of the disease. We invite the attention of the Local Government Board to the matter.

The Public Health (Ireland) Bill.

THE following notice of motion, given by Mr. Gray, M.P., was discussed at the Dublin Corporation on Monday last:—"That we, the Corporation of Dublin, being the sanitary authority, think it our duty to press upon Government the urgent necessity of passing for Ireland, without further delay, a Public Health Bill similar to that passed for England so long ago as 1875; that the present Irish Public Health Bill, which has now been three years before Parliament without an opportunity for its discussion ever having been afforded, requires amendment in many important particulars to assimilate it in principle to the English Act, and to make it effective for the purposes for which it was intended; that a copy of this resolution be sent to the Chief Secretary, to Sir M. E. Hicks Beach, Bart., M.P., and to the Attorney-General, and also to each sanitary authority in Ireland, with a request for their co-operation in urging the necessity of passing the Bill with the requisite amendments this session."

Ergot in Hæmorrhoids.

DR. LANSING writes to the *Philadelphia Medical Times* that "considering the pathological condition denominated hæmorrhoids to consist in an enlarged condition of the veins (an increased length and diameter, as a result of hæmostatic pressure at some time), which continues after the inducing cause or causes are removed, simply on account of relaxed and feeble condition of their coats, and conceding the power of ergot upon that greatest aggregation of unstriped muscular fibres in the human system—the uterus; also its power in the capillaries, where the presence of the unstriped fibre has with difficulty been determined, as in hæmaturia and chronic congestion of the spinal cord, it suggested itself that ergot ought to relieve, and, with so many favourable factors, one could reasonably expect it would cure many cases of hæmorrhoids. Having an intractable case on hand of twelve years' standing, I tested it. I used ergotin in suppositories, four grains each, night and morning at first, subsequently at night only. The first effects of the ergotin was to produce pain for half an hour or more, but after the use of three or four no unpleasant effect attended their use. The hæmorrhage ceased, the congested condition of the parts yielded, the hyperæsthesia was replaced by normal sensation, the hard, cordy condition of the veins passed away, and the slight tumefaction remaining suggested interstitial fibrinous exudation or cellular hyperplasia. Having treated five cases with the ergot, in four of which the result was more satisfactory than I anticipated, the fifth is still under active treatment. Having never seen the treatment suggested, and the result in my case being so happy, I offer it that others may test it, and possibly much relief accrue to a numerous class of great sufferers."

Transfusion and Uterine Hæmorrhage.

IN the *Archives de Tocologies*, for December, 1877, there is a remarkable case in which transfusion was successfully performed for severe menorrhagia in a girl thirteen years of age. All the usual remedies were employed without success, and the patient's symptoms became alarming. Uncontrollable vomiting came on, and all nourishment was rejected. Her complexion was cadaveric, the skin was cold, the voice inaudible, and the pulse could no longer be felt. Consequently the operation of transfusion was resolved upon, the father furnishing the blood. The apparatus of M. Marthien was used, the blood not being defibrinated. The quantity employed was 170 grammes. The patient rapidly revived during the operation. Afterwards, the feeling of warmth at first felt, gave way to shivering and extreme thirst. The pupils, which had been widely dilated, became closely contracted, and this condition continued for four or five hours. The following morning the pulse was 145; the hæmorrhage insignificant, and the sickness less frequent. Some febrile disturbance followed, but the girl gradually became convalescent, and she left the hospital, about two months from her admission, in fair condition, but still very pale.

The Rain Tree.

AT a recent meeting of the Linnæan Society, Professor Thistleton Dyer described the "Rain Tree" of Mogobamba, South America, under the name of *Pithecolobium saman*. The so-called "rain" is the fluid excreta of cicadas which feed on the juices of the foliage, and its dropping is therefore analogous to the "honey-dew" which sometimes drops from the leaves of lime-trees by the agency of aphides.

Localised Basal Meningitis in Children.

E. C. SEQUIN, M.D., in the course of some remarks on this disease, published in the *Hospital Gazette and Archives of Clinical Surgery*, March 1st, 1878, pages 104, 105, directs attention to the great importance of the ophthalmoscope in the detection of this affection. In connection with other symptoms, the presence of "choked discs" affords strong confirmatory evidence of its existence; when these are present, prognosis as to vision must be most cautious, the probability of ensuing atrophy being borne in mind. For treatment, he recommends iodide of potassium, in doses varying from ten to sixty grains, three times a day, well diluted. He finds the little patients bear this drug well when it is gradually increased. Counter-irritation by means of blisters, at the outset useful. He applies a series of them behind the ears or on the temples. Light nutritious diet and the avoidance of all excitement are the other measures proposed.

Treatment of Furuncles—Note on a New Property of Arnica.

As the result of physiological experiments, Dr. Planat (*Lyon Medical*) has been led to the use of arnica in all cases of superficial acute inflammation, as furuncles, anginas, erysipelas, &c. He states that arnica aborts all furuncular eruptions, except those accompanied by diabetes, with remarkable promptness. For external use he employs: *Recipe.*—Extract of fresh arnica flowers, 10 parts; honey, 20 parts. If this is too liquid he adds lycopodium. The mixture is applied to the inflamed part, and covered with oil-silk. Equally good results will be obtained in the same cases by the internal administration of tincture of arnica in doses of twenty-five to thirty drops every two hours. M. Planat adds that the extinction of the furuncular eruption is so rapid that it seems impossible to deny a specific elective action.

Fraudulent Syr. Rhœados.

PROF. TICHBORNE exhibited at a recent evening meeting of the Pharmaceutical Society of Ireland, a specimen of so-called syr. Rhœados, which had been offered by a London house, and which was simple syrup coloured by magenta. Mr. H. N. Draper detailed a process for the detoction of magenta by extracting it with chloroform.

The Hospital Saturday Fund in London.

THE second meeting of the board of delegates was held on Saturday last, at King's College Hospital, Lincoln's Inn Fields. Mr. T. Hughes (Chairman of the Council) who presided, said they wanted to get £10,000 this year, and he considered it was a very moderate sum for two millions of people to give in connection with a work of that nature, because the large majority of those who contributed were the people who received the funds of the institutions. Last year, also we protested against ladies being exposed at street stalls to the inclemency of the weather and other annoyances incidental to the London streets from, early morn till night. It is highly gratifying that so many ladies should offer themselves for these disagreeable duties, but it is also the duty of medical men to point out the dangers to which they are thus exposed, and we are delighted with the suggestion made on Saturday last by Mr. Hughes to secure some 500 young men, who, as soon as their work was completed, would go and stand here and there, and thus secure a considerable accession to their funds. A resolution to the effect that it was desirable to hold central meetings with the object of securing sympathy for, and giving publicity to, the work of the fund was agreed to, and the Council adjourned.

We gave expression to these views in our last, and are pleased to observe that the chairman has taken the trouble to impress the same upon the managers and contributors to this fund. As we have before remarked, the working classes of Birmingham put to shame, in this matter, those in London, and it is time the reason was investigated.

Diabetes and Tobacco.

WE are acquainted, says the *Pacific Medical and Surgical Journal*, with a medical man, who after using tobacco freely for upwards of thirty years, abandoned it as a bad habit at the age of 62. Diabetes, or at least polyuria, ensued very speedily, and in a few weeks he was greatly debilitated. He then assumed the use of the weed, and the diabetes soon ceased. Very distressing disturbance of the heart's action then ensued, which did not disappear until he had made a long trip overland. This appearance of sugar in the urine, after relinquishing the habit of smoking, is certainly very singular, and trifling as the circumstance may seem, it is not altogether unworthy of the attention of those who are studying the etiology and pathology of diabetes. We know that there are several circumstances which may give rise to a temporary attack of this affection, such as injuries to the nervous system, liver, and other parts; the influence of certain poisons circulating in the blood, &c.; and perhaps the sudden abandonment of a protracted influence in the use of a mild and soothing narcotic may have been followed by an irritable state of the nervous system, sufficient in conjunction with some other predisposing cause to excite a temporary attack of diabetes.

ST. PETERSBURGH still suffers under the unenviable notoriety of being the most unhealthy city in the world, having at the present time a mortality exceeding even that of the cities of our Indian Empire. According to the last official weekly returns the death-rate in St. Petersburgh was 59 per 1,000 of the population, Madras 58, Buda-Pesth 50, Turin 46, Venice 44, Bombay 43, Naples and Alexandria 41, Munich 40, Rome 38, Vienna 36, Calcutta 33, Brussels and Breslau 32, Paris 31, New York 27, and Berlin 26. Out of 761 deaths in St. Petersburgh, the enormous proportion of 153, or one-fifth of the whole were attributed to typhus fever.

THE mortality last week throughout the United Kingdom was somewhat higher than any previous week during the past winter, probably owing to the cold north-east winds which prevailed. The mortality in London was 27, Edinburgh and Glasgow 29, and Dublin 34 per 1,000 of the population. In the other large towns the rates were—Salford 21, Bradford 21, Nottingham 22, Brighton 23, Leeds 25, Birmingham 25, Portsmouth 25, Leicester

27, Bristol 27, London 27, Norwich 28, Newcastle 28, Plymouth 28, Sheffield 28, Oldham 29, Hull 31, Liverpool 31, Sunderland 32, Wolverhampton 32, and Manchester 34 per 1,000 of the population.

At a meeting of the committee of the Birmingham General Hospital, held last week, it was announced that the magnificent sum of £1,000 had been handed over by Dr. Balthazar Foster, for the purpose of founding a special permanent fund for the relief of necessitous patients leaving the hospital. The fund has been called "The Frederick Cohen Fund," in memory of the late Mr. Frederick Cohen, of Hagley House, Edgbaston, who in his will expressed a wish that Dr. Foster would thus supplement the objects of the hospital, in the hope that others might be induced to make donations for the same purpose.

The letter of Dr. Waters, as Chairman of the Medical Reform Committee of the British Medical Association, calling attention to the wishes of the Association for direct representation upon the Medical Council, was simply read by the Council, on Thursday last, *pro forma*, no opinion being expressed for or against. By adopting this course a polite hint was intended to be given to the Association that aspiring candidates for a seat within the classic circle must seek some other road to fame.

The Session of the Medical Council will this year be a short one; it will probably close to-day (Wednesday). Last year the sitting was the longest on record, and less work was done than usual—on the contrary, this year a disposition not to indulge in long speeches and a laudable desire for work have manifested themselves all through, so that probably the result will be a decided gain, pecuniarily and practically, to the profession.

Small-pox caused 55 deaths in London, 10 in Dublin, and 1 in Sheffield; no other cases were reported in any other part of the United Kingdom. Whooping-cough continues to be exceptionally severe in the metropolis, and scarlet fever in Sheffield.

Medico-Parliamentary.

MEDICAL ACT, 1858, AMENDMENT BILL.

In the House of Lords, on Monday night, the Duke of Richmond and Gordon moved the second reading of this Bill.

The Marquis of Ripon opposed the motion. In the present state of the law there were nineteen bodies in the United Kingdom which could give certificates of competence; and the present Bill (which dealt only with England) did not propose to deal peremptorily with this state of things, but was only permissive. The Act of 1858 had effected no improvement in this respect, and although the noble Duke, when he brought in the Bill, expressed a hope that a conjoint board for England at least would be formed, the Bill left the matter wholly optional. The Royal College of Surgeons, the College of Physicians, the Syndicate of Cambridge, the leading men of Oxford, and the University of London, had all considered the Bill and condemned it. The General Medical Council in the course of last week came to the resolution that no medical legislation would be satisfactory which did not provide for the establishment of an examining board in each of the three divisions of the kingdom, and the committee of the Medical Association—a body consisting of 7,000 persons—at their last meeting expressed their opinion in favour of a better system of examination. The Government had by some fatality obtained the assistance of persons holding the most opposite opinions in favour of the measure so far as related to the admission of women and of foreign practitioners—neither of whom considered that their rights had been sufficiently recognised. He did not ask the House to pronounce a decided opinion upon the measure, but hoped that the Government would reconsider the objections which he had pointed out before going into Committee on the Bill. The noble Duke had now a great opportunity of settling a most important question, and placing the matter upon a footing which would give to the public the protection which they had the right to expect.

The Duke of Richmond and Gordon was glad that his noble friend had not taken the decided step of opposing the second reading of the Bill, because if the House had expressed an adverse opinion the settlement of the matter would have been indefinitely postponed. The objections of his noble friend were principally directed to the absence of a conjoint board in each of the three kingdoms, and he would confine his own remarks principally to that point. The history of the Bill was this. During May last year he received a memorial from the General Medical Council, affording him certain information on five points on which they thought legislation desirable. These points he had fully considered before introducing the measure. But it was a remarkable fact that amongst the five points to which he had referred, the formation of a conjoint board was not mentioned. He admitted the necessity of a more uniform system of examination, particularly as the Bill proposed to deal with unqualified practitioners in a more stringent manner than they had hitherto been dealt with. Probably the best mode of dealing with the matter would be by means of conjoint boards for England, Ireland, and for Scotland. He did not think there would be much difficulty with regard to England and Ireland, but there was some difficulty with regard to the establishment of a conjoint board for Scotland, the universities disagreeing to some extent with the corporations, and the Bill in that respect was of a permissive character. Supposing that it was not possible to obtain compulsory powers with respect to the establishment of a conjoint board, he considered the measure a step in the right direction. If the Bill was read a second time he should be glad to consider any amendments in committee.

The Bill was then read a second time.

Medical News.

Royal College of Physicians of London.—April 15th, 1878. Admitted Licentiates:—

Bartlett, Felix Paul, 5 Albert Street, N.W.
Birt, Ernest, County Asylum, Shrewsbury.
Davis, George, 11 Avenue, Blackheath, S.E.
Dumbleton, Edgar Hunt, 81 Commercial Street, E.
Ellis, William Ashton, 59 Sloane Street, S.W.
Gamble, Ernest L. G., 8 Chase, Clapham Common.
Gaze, William Henry, Woodlands, Thames Ditton.
Greenwood, Arthur, 140 Minories, S.E.
Greenwood, Major, London Hospital, E.
Henry, Louis, Ampthill Square, N.W.
Jover, Anthony, 20 Paris Street, S.E.
May, Albert Edward, 5 Clifton Gardens, W.
Moritz, Siegmund, Cheetham, Manchester.
Nicholl, Thomas Vere, 81 Commercial Street, E.
Norton, Ritchie Robinson, University Hospital, W.C.
Oram, Richard Rundell Wm., 28 Great Coram St.
Packer, William Herbert, County Asylum, Gloster.

Reddy, Herbert Lionel, St. Thomas's Hospital, S.E.
Shaw, Chas. Thos. Knox, 8 Guilford Place, W.C.
Stokes, Richard Lingard, 30 Albert Street, N.W.
Vasey, Samuel William, 5 Cambridge Place, W.

Admitted Fellow :—

Bäumler, Christian Gottfried Heinrich, M.D. Erlangen, Freiburg, Germany.

South London School of Chemistry and Pharmacy.—The following prizes were distributed by Mr. Baxter at this School on Monday last :—

Medals.		*1st Certificates.*	
Senior Chem.	Mr. Hutton	Senior Chem.	Mr. Barrow
Junior Chem.	,, Davies	Jun. Chem. & mat. med.	,, Richards
Botany	,, Stonham	Botany	,, Nicholson
Materia Medica	,, Parker	Pharmacy	,, Pocock
Pharmacy	,, Richards		

NOTICES TO CORRESPONDENTS.

Notice to Subscribers.—Subscribers who have not already paid their subscriptions for last year are reminded that they are now due and should be sent to the publishers, who will be happy to acknowledge their receipt.

Mr. Barnard.—The examinations at the college were for the "primary" in anatomy and physiology, not for the "pass." We only publish the "pass lists," having no room for the primary at the various colleges.

Mr. S.—Yes, the communication has been found and will appear in an early number.

Mr. Wilton —Hardly suitable for our columns. Our contemporary, the *Students' Journal*, occasionally publishes effusions of that nature, and would probably accept it, especially as it seems well done.

S. A. F.—Not Surgeon-General Longmore.

The coming Arctic Expedition.—A correspondent referring to the article in our last on this subject, is of opinion that "the advantages of teetotalism are purely visionary. The reason why the percentage of scurvy was lower amongst abstainers than with those who partook of alcoholic stimulants is, that being peculiarly subject to frost-bite they were not sent on long expeditions with the non-abstainers in the late Arctic Expedition." Of course, if this statement be a fact, it will go far to explain the conduct of the champions of Capt. Nares.

W. T. G., M.D.—It is only natural that medical practitioners should regret to hear that another rival was about to enter the neighbourhood. The new comer, however, should call on the former resident medical men and express his desire to work in professional fellowship with them.

An Army Surgeon.—It is impossible yet to give any information; the Report of the Committee appointed to inquire into the dearth of army medical officers has not yet been presented to Parliament. We are promised early information from an authentic source.

QUALIFICATIONS FOR THE REGISTER.

To the Editor of the Medical Press and Circular.

Sir,—I believe there is a Medical Bill before Parliament to the effect that no person is to be placed on the Medical Register unless he is doubly qualified. I have myself the misfortune to hold but one qualification, and I write to ask if you will kindly inform me in the next number of the Medical Press and Circular if the said Bill passes how soon it will come into operation. Do you think it will be this year? I do not know when a Bill passes Parliament whether it comes into force at once or not. Will you do me the favour to let me know in your "Answers to Correspondents" what you think of it? It is not convenient for me to register just now, but it would be ruin for me to be excluded from the Register altogether. Apologising for troubling you with this, I remain,

Your obedient servant,
E. T. W.

[The new Medical Act cannot affect those who are already qualified to enter their names upon the Register without due notice being given. Nevertheless, we should advise our correspondent to register at the earliest opportunity.—Ed. M. P. & C.]

The Actonian Prize.—This valuable prize, for which the Council of the Royal Institution of Great Britain offer one hundred guineas, is announced for competition: essays to be sent in to the Secretary on or before October 1st, 1879. The subject chosen is, "The Structure and Functions of the Retina in all classes of Animals, viewed in relation with the Theory of Evolution." Full particulars on reference to our advertising columns.

Dr. Laffan's letter on "Union Hospitals" is unavoidably held over to our next.

Dr. Harris, Norwich, is thanked for his note.

One Interested will find the question raised and answered in this present number.

F.R.C.S.Ed.—Yes, Dr. Bell Pettigrew.

Mr. Feltoe has asked us to mention that he has been appointed purveyor of "Specialité" sherry to the Paris Universal Exhibition.

A Special Evening Meeting of the Pharmaceutical Society of Great Britain will be held this (Wednesday) evening at 8 o'clock. Professor Bentley will deliver a lecture on "Eucalyptus Globulus."

VACANCIES.

Ennis District Lunatic Asylum.—Resident Pupil. Salary, £50, with apartments and rations. (See Advt.)

Great Northern Hospital.—Ophthalmic Surgeon. Applications to the Secretary at the Hospital, Caledonian Road, N., before May 6. Honorary.

Kent and Canterbury Hospital.—Assistant House Surgeon. Salary, £50, with board and residence. Applications before April 25 to the Secretary.

Rathdown Union, Glencullen Dispensary.—Medical Officer. Salary, £110. Election, April 25.

Royal Cornwall Dispensary.—House Surgeon and Secretary. Salary, £200, with furnished apartments. Applications to the Hon. Treasurer at the Hospital, Truro, before the 24th inst.

Taunton Union.—Medical Officer. Salary, £52 per annum, with the usual extras for midwifery, vaccination, &c. Applications to the Clerk of the Union on or before April 28.

Tralee Union, Brosna Dispensary.—Medical Officer. Salary, £100. Election, 22nd inst.

Waterford Union, Kilmeaden Dispensary.—Medical Officer. Salary, £100. Election, April 26.

Westminster Hospital.—House Physician and House Surgeon. Candidates must have completed their education at this Hospital. Board and residence. No salary.

APPOINTMENTS.

Abbott, C. E., L.K.Q.C.P.I., M.R.C.S.E., House Surgeon and Secretary to the Staffordshire General Infirmary.

Bell, W, M.D., M.R.C.S.E., Honorary Surgeon to the South Dispensary, Liverpool.

Brunton, J., M.A., M.D., Honorary Consulting Surgeon to the Royal Caledonian Asylum.

Drew, C. L., M.B., C.M., M.R.C.S.E., Medical Officer for the Dunchurch District of the Rugby Union.

Ford, A. V, L.K.Q.C.P.I., M.R.C.S.E., Medical Officer for the Kingston District of the Portsea Island Union.

Husband, W. E., L.R.C.P.L., M.R.C.S.E., Resident Medical Officer to the Royal United Hospital, Bath.

Inglis, T., M.R.C.P.Ed., L.R.C.S.Ed., Senior Assistant Medical Officer to the Royal Lunatic Asylum, Edinburgh.

Kilbride, J., L. & L.M.K.Q.C.P.I., M.R.C.S.E., Medical Officer to the Athy Dispensary, Athy Union.

Langworthy, W. F., M.R.C.S.E., Certifying Factory Surgeon for Modbury.

Mackey, S. W., L.K.Q.C.P.I. & L.M., L.R.C.S.I, Certifying Factory Surgeon for the Churchinford District.

Moore, J. D., M.D., Medical Visitor of Houses licensed for the reception of Lunatics within the County of Lancaster.

Pye, W., M.R.C.S., an Assistant Surgeon to St. Mary's Hospital.

Ringer, S., M.D., F.R.C.P.L., Professor of Medicine at University College, London.

Tait, R. K., L.R.C.P.Ed., L.R.C.S.Ed., an Honorary Medical Officer to the North Shields and Tynemouth Dispensary.

Births.

Barnes.—April 7, at Lowther Street, Carlisle, the wife of H. Barnes, M.D., of a son.

Moore.—April 9, at 40 Fitzwilliam Square West, Dublin, the wife of J. W. Moore, M.D., of a daughter.

Moorhead.—April 9, at Coolehill, co. Cavan, the wife of T. H. Moorhead, M.D., of a daughter.

Marriages.

M'Conaghy—Rogers.—April 10, at Ardsallagh, Robert J. M'Conaghy, M.D., Castlefin, to Mary, eldest daughter of John Rogers, Esq.

Squire—Tyerman.—April 11, at St. Saviour's, Maida Vale, Alfred Herbert, youngest son of Peter Squire, Chemist on the establishment of Her Majesty the Queen, to Alice, third daughter of the late C. R. Tyerman.

Deaths.

Atwood.—On April 7, suddenly, William Allen Atwood, L.K.Q.C.P.I., M.R.C.S.E., of Ladbroke Grove, Notting Hill, aged 47.

Burch.—On April 3, at Vauxhall Bridge Road, Sampson Kingsford Burch, M.R.C.S.E.

Cloran.—On March 23, at Loughrea, co. Galway, John Joseph Cloran, L.A.H., aged 62.

Creighton.—On April 10, at the Crescent, Salford, Louisa, second daughter of Joseph Creighton, M.D.

Drew.—On April 9, suddenly, at the house of a friend, Salisbury, Walter H. Drew, M.R.C.S., L.R.C.P., of Tufnell Park, London, aged 31, only son of H. P. Drew, M.R.C.S.

Ebden.—On April 13, at Rondebosch, Cape Town, Laura, wife of Hy. A. Ebden, M.D., late of the Hon. East India Company's Service. (*By Telegraph*).

Elliot.—On April 6, at Bellingham, John Elliot, L.R.C.S.Ed., aged 62.

Fitzgerald.—On April 7, at Carrick-on-Suir, co. Tipperary, Alexis Fitzgerald, L.R.C.S.I.

Griffith.—On April 12, at Ventnor, John Clewin Griffith, M.A., M.B., aged 45.

Hide.—On April 6, at Park Road West, Brighton, John Hide, L.R.C.P.

Kingston.—On April 7, at Walton, Suffolk, William Young Kingston, M.D., aged 30.

McKittrick.—On April 4, at Newtownards, Dr. Robert Orr McKittrick, formerly of Holywood, aged 83.

Orr.—On April 3, at Vauxhall Bridge Road, Robert Scott Orr, Surgeon, aged 51.

Shea.—On March 14, at Diep River, Cape of Good Hope, Henry D. Shea, M.D., R.N., Deputy-General Inspector of Hospitals, aged 66.

Warcup.—On April 4, at Scarning, Norfolk, William Mark Warcup L.R.C.P.Ed., aged 84.

IRISH POOR-LAW INTELLIGENCE.

THE SANITARY CONDITION OF DUBLIN.

PUBLIC MEETING.

A SPECIAL meeting of the Dublin Sanitary Association was held on Friday, the 12th inst., in the Molesworth Hall:—"To decide what steps should be taken with reference to the exceptionally high death-rate in Dublin." There was a large and influential attendance. The chair was taken by Jonathan Pim, President of the Association.

Dr. J. W. Moore, Honorary Secretary of the Executive Committee, read extracts from a report prepared for the occasion. In the year 1874-5 the high death-rate in Dublin came under the notice of the Association, and the committee was directed to take such steps as might be necessary to obtain an official inquiry. In 1876-7 no action was taken because it was understood that the Select Committee on Local Government and Taxation would deal with the question; but, as it did not do so, the Association appointed a sub-committee on the 8th November last to prepare a statement. This, which advised an application for a public inquiry, was adopted, and the Public Health Committee of the Corporation was invited to co-operate. In effect, this body agreed to do so, though intimation was given at the same time (through the report of its health officer) that the inquiry would not afford additional information, might be hurtful by delaying useful measures then in progress, and would probably alarm the public. The Executive Committee disagreed with these views, because if the high death-rate were really due to sanitary neglect it was most important that the citizens should know the fact; while, if not, the inquiry would dissipate alarm. Early in this year a memorial, entering fully into details, mentioning the promised co-operation of the Public Health Committee, and asking for an investigation, was forwarded to the Lord Lieutenant. The reply declined the deputation which had been suggested, but invited a further written statement. The next step was Mr. Meldon's question in the House of Commons on 7th March, to which the Chief Secretary replied, in substance, that the Public Health Committee had stated that they were not prepared to apply for any inquiry, and that, as far as he knew, he could not see sufficient grounds for granting one. Mr. F. W. Pim (Hon. Sec.) then wrote, on 9th March, to Mr. Lowther, pointing out the actual position of the Public Health Committee, which virtually was, the declining to join in an application for a commission of inquiry, but the promise of co-operation in the event of one being appointed. Mr. Meldon's notice of a second question was given on the 19th March, and appeared in the Dublin papers on the 20th ult. This notice was followed by one from Mr. Gray, referring to a report adopted by the Public Health Committee on the 28th December, the report concluding with the statement—"Under the circumstances, and since their last report, the Committee see no reason to apply for or recommend a commission." Of this report the Executive Committee knew nothing, and now concluded by asking the Association were they still of opinion that it would be advisable to press for an inquiry.

Mr. Frederic W. Pim, in moving the adoption of the report just made, regretted the antagonism which existed between the Public Health Committee and the Executive Committee, and took occasion to disclaim any studied hostility on the part of the Association towards the Corporation. (Hear, hear.) The fact was, the Public Health Committee was a very *Conservative* body—etymologically, he meant, not politically (laughter)—and felt a natural dislike to matters being stirred up. The Association had been pouring forth statistics and figures for the last five years. The average death-rate in London for the past six months had been about 22 or 23, that of Dublin 28 per 1,000. Last week the death-rate here was 34 per 1,000. The number of deaths from consumption and other diseases of the chest during the last six months in Dublin had been at the rate of 3,214 in the year, or more than one-third of the whole number of deaths in the year. These deaths were directly traceable to sanitary neglect. If they looked at the matter dispassionately it was apparent that there ought to be an inquiry into the causes of such disease and death, and an independent inquiry was what the Association desired. With regard to what had been said about alarming the public, he wished that the public could be frightened, for, really, their being so would make them alive to the danger. Speaking of the unexpected action of the Public Health Committee, Mr. Pim proceeded to observe that although the Association would not give way upon the question, they were anxious to keep on good terms with that body, without whom nothing could be done in a sanitary way, as they were the constituted authority. If, however, this constituted authority should do nothing whatever, it would become necessary for the Association to go in for very sweeping measures. (Hear, hear.) They had freely criticised the proceedings of the Public Health Committee, and should continue to do so. This criticism was useful, coming from an independent body of gentlemen, whose only interest in the subject was that of keeping themselves, as well as their neighbours, from sickness. Mr. Pim concluded by saying that nothing could be more lamentable than that the Corporation should consider that they had made a declaration of war upon this matter, and he hoped that they would be willing still to join them in seeking for that which they thought would be of the greatest importance and benefit to the city—namely, a public inquiry.

Surgeon-General Crawford presumed that he had been requested to second the resolution, from the fact that he was almost a perfect stranger in Dublin. He was not, however, a stranger to its sanitary condition; he had in his hand a report of the Registrar-General, in which he found a large mortality to have taken place lately from small-pox; now what had been said as to epidemic diseases not being under the control of the Public Health Committee, was inapplicable regarding small-pox. He would

not throw discredit upon the practice of vaccination in Dublin, but wished many to mention that up to the present, no case of this disease had taken place in the garrison of Dublin, of which he was principal medical officer, and that in the severe epidemic of 1872, the number of cases was trifling. The same immunity from the disease existed whenever the troops were serving, and this was especially so in India, where small-pox was always epidemic. Vaccination was perfectly successful there, and in his opinion, after thirty years' experience, it was a perfect preventive of small-pox. Having regard to all this, it was not creditable to the city of Dublin that they should have what must be called, he was afraid, an epidemic of small-pox now amongst them. Surgeon-General Crawford next drew attention in a forcible manner, to the extremely defective sewerage even in respectable localities in Dublin, and to the number of deaths from typhoid fever as a result. Alluding to pulmonary complaints, including all chest affections, or destructive lung diseases, these he continued, were both in Dublin and elsewhere, the result of sanitary conditions which were perfectly capable of remedy. With regard to these diseases in particular, he would say that the Sanitary Association was doing good service in calling attention to the fact that they were not only remedial, but were also preventible. In conclusion, he commended the Sanitary Association and its work to the people of Dublin, he knew no better mode of working out sanitary reforms than that of informing the public through such a medium (hear, hear).

Mr. Dawson, T.C., expressed regret that any misunderstanding should have arisen, and said that he was most anxious to cordially co-operate with the Association so long as he thought the sanitary improvement of the city was the entire object in view. He wished to propose an amendment: "That the words 'though purporting to have been adopted in December 28th,' be omitted from the circular convening the meeting." The Public Health Committee wound up their last report by saying that they did not see the necessity of, and that they would not recommend an application for a commission, but they would give cordial assistance to any society whose object was to improve the sanitary condition of the city. There was no doubt the death-rate of Dublin was deplorably high, and everyone regretted it. There was a Public Health Bill now before Parliament, which would give the Corporation all the power they required to lay out the necessary reforms, and he trusted it would be unopposed by the citizens of Dublin. If the Association aided in having that Bill passed, they would do a hundred times more to reduce the death-rate, and clean the streets than by promoting any Commission.

Mr. Shackleton said he would ask Mr. Dawson to withdraw his amendment, because the words to which he took exception did not appear in the report at all, and the Association was willing to withdraw them, as they were supposed to contain an *inuendo*. These little matters of words should not cause a difference of opinion between them. He was prepared to speak well of the Public Health Committee, for on a recent occasion he had found them most courteous and anxious to do whatever they could to improve the health of the city. (Hear, hear.)

After some conversation, Mr. Dawson consented to withdraw his amendment.

The report was then adopted.

Dr. Grimshaw moved:—"That the Executive Committee be directed to communicate with the Chief Secretary for Ireland, requesting him to receive a deputation from the Association, to lay before him a statement of their reasons for believing a public inquiry necessary." He said that the Association did not seek for a Royal Commission, but for an ordinary inquiry by a properly qualified Local Government Board Inspector. An inquiry of this sort was not a lengthy proceeding at all, and in England, where such inquiries had been held, the action had been conclusive. The building clause in the Bill now before Parliament, alluded to by Mr. Dawson, had been suggested by the Association. The Corporation had ample powers at present to construct abbatoirs.

Dr Henry Kennedy seconded the motion, which was adopted.

Mr. Shackleton was called to the second chair, and on the motion of Mr. La Touche, seconded by Dr. Grimshaw, a warm vote of thanks was passed to Mr. Jonathan Pim for presiding.

The proceedings then terminated.

LIMERICK DISPENSARY.

RESIGNATION OF DR. CAREY.

Mr. NASH read the following letter from Dr. Carey:—

"To the Hon. Secretary of the City of Limerick Dispensary Committee."

"DEAR SIR,—After a service of forty-seven years as one of your dispensary medical officers, I feel a necessity of rest from active duties in the evening of my life, and, therefore, beg to tender to you my resignation of the trust the committee and guardians have so long reposed in me, which I have endeavoured to the best of my ability faithfully to maintain. I offer my resignation in the full confidence that the guardians will award me the maximum amount of superannuation that the law permits them to allow; and I entertain this feeling, not alone on account of my long, and as I hope, faithful services, but also in view of this fact, that for eighteen years my labour was given gratuitously to the poor in the Limerick Dispensary before the passing of the Medical Charities Act. I cannot sever may connection with the members of the Committee and the Limerick Board of Guardians without an expression of my very deep thanks for the invariable kindness and consideration I have experienced at their hands.

"THOMAS CAREY, M.D. & L.R.C.S., L.S.A."

Mr. Nash read the following certificate from Dr. Delandre:—

"I certify that I have seen this day, Dr. Carey. In my opinion, he is no longer able to discharge the functions of a dispensary medical officer. He is seventy-three years of age, and he suffers from frequent fainting fits. I believe, that for some years past, he has performed his duties at the risk of his life. "G. DELANDRE, M.D.

"Limerick, March 27, 1878."

Mr. Cronin—I beg to propose that we accept the resignation of Dr. Carey. I regret very much that we are losing the services of so useful an officer.

Dr. Butler proposed: "That it is the sense of this meeting Dr. Carey should be granted the highest superannuation allowance which the law permits."

Archdeacon Hare had much pleasure in seconding the proposition, which was unanimously agreed to; and it was ordered to have a recommendation in accordance with the spirit of the resolution made to the Board of Guardians.

The Chairman called attention to the fact that Dr. Carey had not resigned the office of Registrar of Births. Dr. Carey expressed his desire to resign everything.

Unanimously resolved:—

"That this meeting desires to express its regret at losing the services of Dr. Carey, and in doing so, wishes to return its best thanks for the very able and charitable manner in which he discharged the duties of his office for the past forty-seven years."

M. FÖRSTER, of Munich, has recently determined, with a Pettenkofer apparatus, the excretion of carbonic acid by a large number of children, from the sucking stage up to ten years, and he finds that for 10 kilogrammes body weight they always excrete about 10 to 12 kilogrammes CO_2, or nearly three times the quantity given by adults in similar circumstances. Hence a comparatively larger supply of food is required for maintenance of the body in children than in adults.

MOUNTMELLICK UNION.

DR. WILKINSON'S SUPERANNUATION.

Mr. Cobbe brought forward his notice of motion to rescind the resolution granting the increase of superannuation to Dr. Wilkinson; and that we only give two-thirds of the salary paid by the ratepayers—£43 0s. 6d.

Mr. Betts appealed to Mr. Cobbe to withdraw his resolution for £43, and make it £52.

Mr. Cobbe said he was willing to treat Dr. Wilkinson with every consideration. If Mr. Betts proposed an amendment for £52, he would withdraw his motion.

This course was adopted, and an amendment was put and carried fixing the superannuation at £52.

ATHY DISPENSARY.

The Local Government Board forwarded a communication pointing out that the rate of remuneration proposed to be paid to Dr. Kilbride for his temporary services while acting as medical officer for the Athy Dispensary District, in room of the late Dr. Mara, was not stated, and also requesting to be informed if Mr. Williamson, whom the guardians proposed to remunerate for the performance of the duties of medical officer during a certain part of the time of the late Dr. Mara's illness, was legally qualified to undertake the duties of medical officer.

The Acting Clerk informed the guardians that he had replied to the Local Government Board to the effect that the rate of remuneration proposed to be paid to Dr. Kilbride was £3 3s. per week. He had ascertained from Mr. Williamson that he held no medical qualification but that of Licentiate Apothecary; that Mr. Williamson stated that in the absence of any medical officer, he was obliged to attend the patients applying at the dispensary, and also those in the town of Athy at their own houses during the time stated in the minutes of the 27th ult. The acting clerk added that it was for the extra duty rather than as a qualified medical substitute, the dispensary committee and the board of guardians proposed to remunerate Mr. Williamson.

The Local Government Board replied, sanctioning the rate of remuneration proposed to be paid to Dr. Kilbride, but with regard to the proposed payment to Mr. Williamson, they added that the employment of an unqualified person, as in the present instance, was quite irregular; but the services having been rendered, they would not now oppose the payment.

The Hon. Secretary of the Athy Dispensary Committee forwarded an account that had been furnished by Dr. Young for five guineas for one week's services as temporary medical officer.

Chairman—You cannot pay five guineas, when Dr. Young wrote a letter to the board offering to discharge the duties at the rate of three guineas a week.

Acting Clerk—His letter was to the effect that if he were appointed for two months he would act for three guineas per week.

Chairman—In reply he was informed that he would be paid three guineas a week during Dr. Mara's illness, and when he had acted for one week he became ill himself, and Dr. Kilbride had to be appointed; under these circumstances you could not pay him more than three guineas.

Ordered, that Dr. Young be paid three guineas for the week he acted.

WATERFORD GUARDIANS.

KILMEADEN DISPENSARY.

Moved to advertise for a medical officer in place of Dr. Baldwin, at a salary of £100 a year, exclusive of fees. They proposed to reduce the salary from £120 and £100, on the ground that the district was small, and that the increase from £100 to £120 had been given before the sanitary fee had been added to the salary. They recommended that Dr. Cutlar be paid out of the late Dr. Baldwin's salary.

Captain Power opposed the motion. The doctors in Kilmeaden got very little practice, and could hardly live on £120 a year. He would move that the report be referred back to the committee, in order to have the salary fixed at £120.

Mr. Clampett—The whole work was done formerly for Tramore and Kilmeaden for £80, and now they were asked to pay £240, without other fees.

Dr. Mackesy did not think a gentleman could support himself and keep a horse on £100 a year. Prices were different now from what they were when £80 a year was paid.

The motion for the adoption of the report was then put and carried, the voting being, for 14, against 9.

Electricity in Nervous Vomiting.

Professor Semmola states that since 1858, when he published his first case, he has had numerous opportunities of observing the complete and prompt efficacy of electricity by the continuous current, in nervous vomiting. Not only is it a certain and speedy remedy in this form of vomiting, but it is also of great utility in assisting the diagnosis of vomiting from organic causes, for in all cases in which this is not primarily and exclusively nervous, the application of electricity in order to secure the toleration of food is useless.

THE GENERAL MEDICAL COUNCIL

OF

EDUCATION AND REGISTRATION.

SESSION 1878.

[OWING to the great length and importance of the debate on the Conjoint Scheme, we were, in our last, unable to complete the report of the third day's proceedings of the Council.]

THIRD DAY.—DEBATE ON THE MEDICAL ACTS' AMENDMENT BILL—(*continued*).

After some discussion as to the order of business, it was decided to consider Dr. PITMAN'S motion next.

Moved by Dr. PITMAN, and seconded by Dr. ROLLESTON:—

"That the duties of the Medical Council in relation to the various licensing authorities (whether in separate or in joint action), should not be extended to the initiation of the examination rules, under which qualifications are to be granted, but should remain restricted, as now, to duties of superintendence and control, with power of making representation to the Privy Council in cases of default."

Dr. PITMAN then explaining his motion, said it would be observed that the motion contained a principle in direct opposition to clause 14 of the Bill. The clause recognised the existence of certain duties and certain powers, and states that it is necessary that the powers should be extended. But it will be seen on reading the clause that though it increases the duties it does not increase the powers. In a side note it is stated that it shall make rules to secure efficiency and uniformity of examinations. He considered it very important that the Act admitted the necessity of uniformity. The duties are four:—

1. To make or alter rules for examinations.
2. To determine the subjects of examination.
3. To determine the standard for passing.
4. To lay down rules for the conduct of examinations.

The only "further powers" which are provided for carrying them out appeared to be the same as those granted in the Act of 1858. Let them consider the time that it would take to frame rules for all the corporations. Some idea of this might be gathered from the time it took (some fifty sittings) the framers of the Conjoint Scheme to decide as to the rules for it. Was it likely that the universities would submit to have the conditions for the acquirement of their degrees laid down by the General Medical Council. It was, in his opinion, not to be expected that the universities should consent to have to examine and educate their students after the fashion laid down by the Medical Council, and then send them out to the world as being their own produce. There were, indeed, subsequent clauses which gave to the corporations the right of appeal to the Privy Council, which appeared to him to place the Council in an undignified position. It would be better that examinations should be regulated by a committee of reference.

Dr. ROLLESTON, in seconding the motion, said that the one objection in the motion was that it might be thought that the Council was trying to restrict its own powers. But this was not the case. He thought the Council was worthy of higher things than the regulation of the details of examinations—that a committee of reference which would be necessarily composed of men who had had more recent experience of students than had the gentlemen composing the Council would be much better fitted to decide such questions. He hoped that the regulation of examinations would be intrusted to such a committee, as nothing would be more fatal than that it should be intrusted to Government. In support of this he mentioned an instance in Germany where a government official had in a most mischievous manner struck out an important subject from an university curriculum.

Dr. WOOD, Sir DOMINIC CORRIGAN, and Sir WILLIAM GULL spoke in favour of the motion.

Dr. PITMAN proposed that the words "in general" should be inserted in the motion after the word "should." It was decided to put the motion in its original form, and to decide whether or not they should insert these words after. It was decided to substitute the word Medical for Licensing, so that it might read "medical authorities."

Both the motion and the insertion of the words were carried by a large majority.

Mr. SIMON then divided the Council on the motion that the Council might resolve itself into committee for the consideration of the bill. The motion was carried.

Clauses 1 and 2 were approved without alteration.

Clause 3. Mr. MACNAMARA said that the body he represented was of opinion that the word triple qualification should be substituted for double, by requiring, in fact, a qualification in midwifery. He said that at first sight it might be considered a too great subdivision of the profession, but in support of the necessity adduced the fact that the Irish Poor-law Boards had found it necessary to insist on a qualification in midwifery for all persons taking Poor-law appointments. He therefore begged to put a motion to that effect.

Mr. Macnamara's motion fell through for want of even a seconder.

Prof. WOOD proposed that this Council approves of clause 3.

Mr. SIMON proposed as an amendment "That the Council so far approve of clause 3, in as far that they agree that every registered person should have been tested in Medicine, Surgery, and Midwifery, but as to the way that should be carried out they would refer to the motion on conjoint examinations."

The amendment was carried by 13 to 9.

It being now nearly six o'clock, some formal business was proceeded with until the adjournment.

FOURTH DAY.—PETITION FROM UNIVERSITY OF GLASGOW.

THE minutes of the preceding meeting having been read and confirmed, the petition of Senatus Academicus of the University of Glasgow came on for consideration. It was objected by Dr. Storrar that as the petition was addressed to Parliament, and not to the Council, it could not be properly considered by the latter.

The PRESIDENT replied that it was not in his power to hold back such a document. Whether or not it was to be placed on the minutes was a matter for the consideration of the Council.

It was ultimately decided that the petition should be inserted in the minutes.

DEBATE ON THE MEDICAL ACTS' AMENDMENT BILL—(*continued*).

The Council then resolved itself into committee for the consideration of the Medical Acts Amendment Bill.

It was then proposed by Dr. ROLLESTON that they should proceed first to the consideration of the clauses relating to dental practice. He pointed out a clause in the letter printed in the programme from the President of the Dental Reform Committee, and considered that it would accord well with their previous decisions to adopt that clause as a motion expressing their opinions as to the course dental legislation should take.

The clause was accordingly proposed as the following motion :—

"It is not desirable the Medical Council should be required to undertake to originate a new scheme of education as proposed in the Medical Bill, clause 23 (1), but that the Council should have full power to approve, modify, or refuse its assent to the educational details from time to time proposed by the Surgical Bodies authorised in the Bill to grant dental qualifications."

Dr. TURNER suggested that the words "medical authorities" should be substituted for surgical bodies.

The motion in this form was agreed to.

Dr. ROLLESTON then proposed that it is desirable that provision should be made in the Medical Act (1858) Amendment Bill, which should provide for the registration of dentists.

Mr. SIMON then proposed that the words "or otherwise" should be inserted after Medical Act.

This proposition was supported by Sir DOMINIC CORRIGAN, who said that he did not think that the Council ought to be burdened with the work of regulating dental education and registration. There was not a man round the table who knew anything more about dentistry than any old lady who had ever had her teeth looked at.

The original motion was carried.

Dr. ROLLESTON then proposed, as a resolution, "That it is not desirable that this Council should be required to undertake to originate a new scheme or examination rules, but that it shall be entrusted with some such supervisory power as it already exercises with regard to medical examinations."

Sir DOMINIC CORRIGAN objected to this motion, because he considered that the Council would make itself ridiculous if it undertook any supervision or other connection with dentistry.

The motion was, however, carried.

Dr. AQUILLA SMITH objected to the use of the word "surgeon" or "surgery" in connection with dentistry.

In reply to this, Mr. SIMON pointed out that the College of Surgeons already gave a licence in *dental surgery*.

Mr. TEALE objected to the discussion of this as being a mere minor point.

Dr. WOOD replied that this was a matter of principle. If a dentist was to be called a dental surgeon how was the public to distiuguish between a dentist and a surgeon practising dentistry?

Mr. SIMON said he objected to an effort to tyrannise over the popular use of a word—that the Council wasted its time in such a trivial matter. Was not the word surgeon used in other combinations, as in "veterinary surgeon?" It was ridiculous to attempt to protect the word surgeon in such a matter.

Dr. STORRAR said that he entirely agreed with Mr. Simon, that the attempt to thus restrict the word surgeon was Quixotic, and an attempt to put an unjustifiable slight on a useful and now well-educated body of men. He pointed out the dictum of Lord Chief Justice Cockburn nineteen years ago with regard to a prosecution against a dentist for using the title dental surgeon, when Lord Cockburn dismissed the charge against the dentist saying that the adoption of such a title was quite justified by common and universal usage.

Dr. AQUILLA SMITH then put his objection in the form of a motion.

Sir DOMINIC CORRIGAN rose to support Dr. Aquilla Smith's motion. He said that he attached no value to the dictum of Lord Cockburn. That it was notorious that lawyers were generally ignorant of medical matters, and that giving dentists such a title would be to put them in a false position.

Dr. ROLLESTON said that it would be a great pity that it should go forth that such an ungracious act should be contemplated by the Council. He himself was a physician. It was not likely that such a title as dental physician would ever be used, but he should be proud to be associated in such a manner with so useful and skilful a body. He himself had thirty-two good reasons in his head for admiring dentists, and he considered that there was scarcely a class which had done so much to improve and elevate its position in spite of much needless discouragement.

Mr. SIMON begged Dr. Aquilla Smith to withdraw his motion.

This was refused, and the motion was therefore put. It was however lost by a large majority, only three voting for it.

It was proposed by Dr. ROLLESTON to substitute clause 11 of Sir John Lubbock's Bill for clause 5, paragraph 23 of the Earl of Richmond's Bill.

This motion was carried.

Sir J. PAGET then proposed that the Council approves of that portion of the Bill relating to the registration of dentists.

This motion was also carried.

Dr. TURNER proposed that they should then pass to the consideration of the part of the Bill relating to the registration of foreign and colonial diplomas.

Mr. SIMON said, in connection with this, that he objected to the use in the Act, sec. 7, line 7-11 of such an exact term as testifying equal or greater knowledge than that qualifying to practise in the United Kingdom. It was obvious that they could not testify to any examination—being up to such a standard without visiting it, and this was clearly impossible in the case of foreign examinations. On the other hand, they might from general repute to form printed regulations, &c., form such an opinion as would justify them in saying that they felt satisfied with the competency of the holder of a foreign diploma, and he thought that the Act should have words substituted to that effect.

This suggestion was put on the form of a motion and carried.

Some discussion then took place in the clause requiring an applicant for registration of such a diploma to have been in practice ten years abroad.

With regard to the time of probation, Dr. WOOD proposed that in clause 5 five years be substituted for ten years.

Mr. SIMON proposed as an amendment, "That he have

practised in the part where his qualification was obtained *bonâ fide* for the term of one year."

It was pointed out by Dr. HUMPHRY that they really did not know what was the character of foreign or colonial degrees, and that the choice might be given, instead of residence, of passing one of the final examinations; this would be no hardship on a man who had just completed his course of study, but would be hard on a man who had been qualified for five years.

Mr. SIMON altered his amendment to the form "That the Council are of opinion that sections 5-6 of the Act should be brought into conformity with the resolutions of last year."

The amendment was lost, but the motion with the addition of Dr. Humphry's suggestion was not at once put to the Council.

As it was now 5.30, it was determined to defer the consideration of the original motion until Monday.

It was proposed by Dr. ROLLESTON that the President, Dr. Wood, and Dr. Humphry be deputed to carry the resolutions of the Council to the Lord President on Monday at 1 o'clock.

The motion was carried.

The Council then adjourned.

FIFTH DAY.—DEPUTATION TO THE LORD PRESIDENT.

1. The Minutes of the last meeting were read and confirmed.

2. The PRESIDENT stated that he had laid before the Lord President the following observations :—

The Medical Council deputed the President, Dr. Humphry, and Dr. Andrew Wood to present to your Grace certain resolutions which they have arrived at.

The Council met on April 10th to consider the letter which your Grace forwarded with copies of the Medical Act (1858) Amendment Bill read in the House of Lords on March 19th.

All the subjects on which the Council last year addressed your Grace are dealt with in this Bill, viz. :—

1. The recognition of Foreign and Colonial qualifications in England ;
2. The privileges of Women in regard to Medical qualifications ;
3. The appropriation of Penalties under the Medical Act ;
4. To some extent the Education of Midwives ;
5. And, indirectly, the emendation of the law affecting Certificates of Lunacy.

After the second reading of the Bill the Council may have to suggest to your Grace's consideration certain amendments in various Clauses relating to these subjects, and to some minor points in the Bill, prior to the consideration in Committee.

The Council are aware that your Grace was unwilling to bring in any Government Bill which did not deal with all the chief subjects that were known to need attention in regard to Medical Legislation.

They find, accordingly in the Bill, clauses having reference to subjects that are admitted to be of importance and to need settlements other than those named last year by the Council.

They find clauses relating to the mode of conducting Examinations in the United Kingdom, and to framing Examination-Rules.

They perceive that the permissive principles of combination of any of the Licensing Bodies is continued with modifications.

On this subject a Resolution has been passed by the Council, which forms clause 3 of the Minutes for April 12th, 1878 pp. 37, 38).

If the Bill pass in its present form it would, in the opinion of the majority of the Council, be necessary to make such modifications in the rules as are set forth in the resolutions in clauses 5, 6, 9 of the Council's minutes for April 12th, 1878 (pp. 38—40).

On the subject of the Registration of Colonial Practitioners and other subjects therein, the Council is engaged now.

On the subject of Dentists they have passed resolutions which form clauses 6, 7, 9, 10, 11 of the Council's minutes for April 13th, 1878 (pp. 48—50).

As regards the Registration of Midwives, they have not yet had time before the second reading to pass any resolution. But they have already notified to your Grace (see Minutes Vol. xiv., p. 198, clause 14) :—

"That the Council, without assenting in all details to the scheme of the Obstetrical Society, is of opinion, with the Society, that it would be desirable to provide by legislation for the following two objects :—First, that means under legal sanction should be provided for giving credentials of qualification to competent midwives; and, secondly, that the lives of women in labour should, as far as practicable, be protected from the incompetent." And to-morrow they will receive a deputation from the Obstetrical Society as to the details of their proposal.

The Council are still engaged in considering the remainder of the clauses in the Bill, and will further communicate with your Grace thereon after the Easter recess.

Upon that, his Grace said that he would give the fullest attention and consideration to all those particulars upon which the Council had already resolved, and to any further resolutions which the Council might pass at such times as the Council thinks fit ; that is, either during the present session, or at any subsequent session that may take place at the will of the Council, if it takes place before the House of Lords goes into committee on this Bill. He then said that he was going to bring forward the second reading this afternoon ; and that, in consequence of that, and some important business in which he is engaged, he was unable to receive the deputation of the Obstetrical Society which he had wished to do this afternoon. He was so occupied that it was impossible for him to do so ; but, as the Easter recess begins to-morrow, and he would not be able to see them at all now until after the Easter recess, having understood that they were to meet this Council to-morrow, he would be happy to receive through this Council any further communication on the subject, if there be any to be forwarded after the interview with the Obstetrical Society.

Then he added that he had every reason for hoping that this evening the second reading of the Bill would be passed, and then that in that case he would introduce the Bill in committee for the consideration of all the amendments which had been presented to him, and for their full discussion, at the earliest possible period at which it could be done. Considering the other arrangements of the Government; and the work before the House, the earliest day at which he could undertake to do this would be on the 20th of May next, and in his Grace's judgment if the discussion could not successfully take place on the 20th May or thereabouts, there would be no chance of the Bill passing this year ; that he would give his best attention to all amendments which should come before him before the 20th of May, and on that day he would proceed with the consideration of the Bill in committee,

I thought it my duty to say—and I trust the Council, as well as my colleagues, will not think I went too far in this statement—that we had not yet considered fully the whole of the Bill, but I was quite sure I expressed the individual feelings of the members of the Council, that whatever opinions there might be as to the value of the Bill, we were all very sensible of the great trouble he had taken.

A letter from Dr. Waters, the President of the Reform Committee of the British Medical Association, was then read, asking for some opportunity of representing their views to the Council. After some discussion it was decided to place Dr. Water's letter on the minutes, and that the President and such members of the Council as wished to be present, should receive Dr. Waters at 11 a.m. on Wednesday.

DEBATE ON THE MEDICAL ACTS' AMENDMENT BILL—(*continued*).

The Council then resolved itself into committee to consider the Medical Acts Amendment Bill. On this subject the first motion was that which Dr. Wood had mooted on Saturday.

Dr. WOOD said that on more mature consideration he had somewhat altered his views on the subject, and that he could not therefore still adhere to the terms of his motion. He thought that the ulterior object of this clause was to secure for the British medical man the reciprocal privilege of practising in the colonies and abroad, and that for such an object he did not think the terms of his motion were sufficiently liberal. He now thought that a two years' residence would be a sufficient guarantee of a man's not having gone abroad merely for the purpose of getting a diploma on what he, the candidate, hoped might be easier terms.

Dr. ROLLESTON said that the enactment of any such probationary period of practice was superfluous and useless. That practice might mean anything or nothing. Stripped to a point of fact, it came to nothing more than putting a brass plate on a door. If they defined practice as dressership or house surgeoncy, that was another thing; but such a requirement was absolutely out of the question in the present case. What they wanted was, on the one hand, to prevent the surgeon of a colonial ship from being disfranchised as soon as he touched England, and being unable to take back another cargo of emigrants, and on the other, to prevent a man from just running across the Atlantic for the purpose of obtaining his diploma; and he thought that this might be met by inserting a clause making it obligatory for any holder of a colonial diploma, claiming registration, to have resided in that colony for at least two years before taking his diploma; and he would therefore put a motion to that effect.

Dr. WOOD then withdrew his motion.

Dr. STORRAR said that he knew something about the colonial universities, and he felt sure that some of their qualifications were equal to, or better, than some British qualifications, and that he thought it would be invidious, nay, even offensive, to the colonies to insert such a clause as that in the Bill before them. In the United States, he was free to admit, that there were faculties for gaining qualifications, against which it would be only right for them to be extremely guarded; but from conversations that he had held with Sir James Fayrer and others, he felt sure that it was the desire of most colonial universities to make the regulation for the acquirement of their degrees as stringent as possible.

It was then moved by Dr. PITMAN, and seconded by Dr QUAIN, that the Council adheres to its resolution of last year in regard to the registration of colonial diplomas (Minutes, vol. xiv., p. 119, clause 5).

Sir J. PAGET said that it should not be lost sight of that for the last three days they had been expressing great dissatisfaction with their own system of examinations, and that with every wish to be as liberal as possible to the colonies, he thought they ought to take care lest they fell into the error of being more liberal to the colonies than themselves.

Dr. STORRAR said that the question narrowed itself to giving some protection against persons who could not pass here going to the colonies to obtain their diplomas, and that this risk was, in his opinion, so microscopic, that it was beneath the dignity of the Council to consider it.

Dr. HUMPHRY said that after all he thought Dr. Wood's discarded motion was the most liberal of all, as instead of placing the colonial diplomate on a separate register, it gave him the opportunity of getting in the general register, and so be on a fair and equal basis with English practitioners.

Sir. W. GULL proposed an amendment, and was seconded by Dr. HUDSON:—

"That where a person who has been *bona fide* domiciled in any British possession can show evidence of holding some recognised medical diploma or diplomas, as hereinafter defined, granted in such British possession, and which may be satisfactory to the Medical Council, and that he is of good character, such person shall, upon payment of the registration fee, be entitled, without examination in the United Kingdom, to be registered as a colonial practitioner in the Medical Register."

The amendment was negatived.

Dr. ROLLESTON proposed that colonial practitioners should be admitted to the register on passing one of the final examinations here, and their colonial diploma should be sufficient credentials to admit them to any of the final examinations.

Dr. STORRAR said that he should like to know whether this would force every authority to admit colonial practitioners to the final examinations of their degrees, *e.g.*, to give them an M.B. degree on passing the 2nd M.B. examination only.

Dr. ROLLESTON modified his resolution so as to make it optional on authorities to do this, and ultimately withdrew his motion.

Second Amendment: moved by Dr. ANDREW WOOD, and seconded by Mr. TEALE:—

"That in clause 5, lines 1 to 4, of the Bill, for the words, 'Where a person who either is not domiciled in the United Kingdom, or has practised medicine or surgery or a branch of medicine or surgery, for more than ten years elsewhere than in the United Kingdom,' there should be substituted the following words: 'Where a person has been domiciled in a British possession for two years immediately preceding the granting of his diploma."

The amendment was carried, and, having been put as a substantive motion, the following amendment was moved by Mr. SIMON and seconded by Dr. STORRAR:—

"That where a person who has been *bonâ fide* resident in a British possession outside the United Kingdom shows that he is of good character, and holds a recognised diploma or diplomas (as hereinafter defined) granted in a British possession, such person shall, upon payment of the registration fee, be entitled without examination in the United Kingdom, to be registered as a Colonial practitioner in Medical Register."

This amendment was carried, and, having been put as a substantive motion, was agreed to.

The Council then resumed and ballotted for the Executive Committee, whereupon the following members were found to be duly elected—Sir James Paget, Dr. Andrew Wood, Dr. Quain, Dr. Humphry, Dr. Aquilla Smith, and Mr. Simon.

The Council then went again into committee on the Bill.

Clause 6 was, in substance, approved.

With regard to clause 8, Dr. HALDANE pointed out that in it no mention was made either of examination or diploma.

Mr. SIMON explained that this clause was only designed to meet very exceptional individual and personal cases, of the merits of which the Council would be the judges.

The clause was then approved.

Clauses 9, 10, 11, 12 were then in substance approved.

Clause 13.—Mr. BRADFORD said that he should like to point out that by this clause the power of erasing a practitioner's name from the register was delegated to a small committee of five, of which three would form a quorum, so that, practically speaking, the dictum of two was sufficient to remove a man from the register. That he felt that this was too serious a power to be used in such a manner, and he hoped that the Council would reserve that power to its general body. In ordinary courts of law there was a jury of twelve, and he thought it un-English to administer the matter in such a manner.

Dr. WOOD said that the power of erasing a name from the register was indeed a tremendous power—a power which was capable of blasting a man's prospects for life. He thought that such a committee was too small a body. He had no doubt but that such a body would feel their immense responsibility, but he feared that this would lead them to judge too technically. Hitherto the action of the Council had shown great justice in this matter, but its tendency had always been to temper justice with mercy, and he feared that such a tendency would be lost if the power were deputed to a small section of the Council. He was glad to see that this clause gave a power of appeal, but beyond that, he hoped that they would leave things as they were at present.

It was then moved by Dr. APJOHN, and seconded by Mr. SIMON,

"That questions relating to the erasure of names from the Medical Register for infamous or disgraceful conduct in a professional respect ought, in the opinion of the Council, to be reserved for the decision of the general body of the Council, and that it be recommended to the Lord President to amend clause 13 of his bill accordingly."

Dr. AQUILLA SMITH said that he agreed with the preceding speakers with regard to the power being by the Act vested in too small a number, and that, in addition, it appeared to him to needlessly complicate the machinery of the Council by adding a judicial to their already numerous committees. If the power was to be vested in a committee, why should it not be exercised by the executive committee, its decisions being subject to the approval of the General Council.

Dr. ROLLESTON said that in this matter the Council did not act as jurymen, but as judges, and that the whole Council was too large a body to act as such. He thought that the smaller the body the better, because they would feel the weight of the responsibility more, and would hence have more method in their decisions. They would be responsible both to the profession and the public, and open to criticism from both. If the power were vested in the general body of the Council, he thought the responsibility would be too much diluted, and might come to be loosely exercised. A check might be imposed on such a committee by making their decisions subject to the veto of the General Council. It was an acknowledged axiom that a guilty man would rather be judged by a jury, and an innocent man by a judge. He therefore hoped that the power would be vested in a committee subject to the veto of the council.

The PRESIDENT said he should like to draw the attention of the members to the fact that hitherto their practice had varied a great deal. That this power had in some instances

been exercised by the General Council, in some by the Branch Councils, and in others by the Executive Committee, and that it was evidently desirable that this state of things should not continue. Questions as to competency had been raised on this account, and that this clause had been inserted in order better to define the conditions under which this power was to be exercised.

Dr. HUMPHRY said that he felt this to be a serious question. That they had to exercise this power with regard to two distinct classes of cases. First, in those in which the culprit had already been convicted in the ordinary courts of law; and, second, in those cases where the Council was the court in which the offence was to be tried. With regard to the first class there evidently need be no dispute, but with regard to the second he could not help thinking that the duty would be better fulfilled by specially chosen persons. Speaking for himself he should, as a judge, feel a graver sense of responsibility, and were he the accused he would rather be judged by 5 than 24. That the question now came before them from a new point of view, as a power of appeal had been instituted, and he thought that this ought to materially influence their decision.

Dr. WOOD said that he supposed that if they delegated this power to a committee, it, like their other committees, would sit in private. The great advantage of making the General Council the court was that it was open to the public, and he did not think that three people in a quiet room constituted an open court. All judges tried and sentenced the cases brought before them openly, and hence he still retained the opinion he had already expressed.

Dr. ROLLESTON replied that he did not think the cases were analogous. That this power that they held was not like that of a judge in court, but like the power the benchers had of disbarring or disbenching one of their own number.

Dr. TURNER pointed out that their court in such a matter was partly private and partly public, for they heard and gave sentence on a case in public, but they deliberated in private.

Mr. BRADFORD said that in his opinion such a committee would be a most un-English institution, and he for one would not like to sit on such a board.

The motion was then put to the vote, and carried.

It was then moved by Dr. HUMPHRY, seconded by Dr. AQUILLA SMITH, and agreed to :—

"That it is desirable the power of erasing from the Medical Register the name of any person who has been convicted in a court of law of a felony or misdemeanour, be deputed to a committee of the Council."

After some formal business the Council adjourned.

SIXTH DAY.—DEPUTATION FROM OBSTETRICAL SOCIETY OF LONDON.

The minutes of the preceding meeting having been read and confirmed,

The President of the Obstetrical Society, Dr. West, with a deputation of the members were then received. (The deputation consisted of Drs. Barnes, Aveling, Priestly, Murray, and Williams).

Dr. WEST said that in the letter he had sent he had dwelt on the main points of a scheme for the education and examination of midwives. It had appeared to the Society that the fees should be small. They had added a requirement for each candidate to have a certificate of good moral character. They considered that important, as there was no doubt that some midwives received unmarried pregnant women into their houses with the understanding that the child should not survive. That in order to prevent a traffic in certificates they recommended that each certificate should be numbered, and that each county should license and examine its own midwives who should not be competent to practise out of their own county. That they ought also to be obliged to have had some training in ordinary sick nursing, as they had met with a large number of midwives who were utterly ignorant of the very rudiments of nursing duties. He said that they had proposed a simple and inexpensive arrangement of examination boards, in which he suggested that the test should be mainly oral. They considered also that the limits for the action of midwives ought to be as clearly defined as possible.

The PRESIDENT asked whether the scheme they proposed agreed with the Bill before Parliament?

Dr. WEST replied that it did not in any way contradict it, but that it related mainly to those matters of detail which in the Bill had been left for the consideration of the Council. That they pointed out in clause 5 there was a permissive power given for the establishment of local boards, but that they did not think that, without some compulsory clause that would come to anything.

Mr. SIMON asked Dr. West if he considered that a central system of registration was needful, and whether or not a local system might not meet the case, and that when a midwife wished to change her residence it might be made necessary for her to get her certificate countersigned to the effect that she had behaved well?

Dr. WEST replied that he did not think that the system would throw any great amount of work on the Council.

Dr. HUMPHRY asked whether it would not be better to have travelling examiners paid by the State?

Dr. WEST replied that he doubted if it would be possible to get men of sufficient standing to accept such an appointment.

Dr. WOOD asked what would be the constitution of the local examination boards?

Dr. WEST replied that they considered that it should consist of the senior officer of health *ex officio*, the two senior officers of the local lying-in institution or infirmary, and the two senior medical officers of the local hospital or infirmary.

Mr. SIMON pointed out that the Bill only made punishable the use of the title of registered midwife.

Dr. WEST replied that registration conferred certain advantages on the women which they thought would be sufficient inducement to make them go through the requirements for registration.

The Council having thanked Dr. West for his ample explanations, the deputation withdrew.

DEBATE ON THE MEDICAL ACTS' AMENDMENT BILL—(*continued*).

The Council then went into committee for the adjourned consideration of the Medical Acts' Amendment Bill.

On the motion of Mr. SIMON the report of last year's Medical Acts committee (Minutes xiv., pp. 194-197) on the proposals of the Obstetrical Society with regard to women acting as midwives, was read.

It was then moved by Mr. SIMON, seconded by Sir W. GULL, and agreed to :—

"That the Council adheres to the opinion which it expressed last year, in accordance with what it regards as the *general intention* of the proposals of the Obstetrical Society, that legislation for the following two objects would be desirable :—'Firstly, that means under legal sanction should be provided for giving credentials of qualification to competent midwives; and secondly, that the lives of women in labour should, as far as possible, be protected from the incompetent.'" (Minutes, vol. xiv., p. 198.)

Moved by Dr. ANDREW WOOD, seconded by Dr. ROLLESTON, and agreed to :—

"That the Council now proceed to discuss the several sections of clause 24 of the Bill."

Moved by Mr. SIMON, and seconded by Sir WILLIAM GULL :—

"That the Council, having regard to its own special purposes and organisation, and to the resources of its office, could not undertake to initiate arrangements (which must for the chief part be local) for the examination, licensing, and registration of midwives throughout the United Kingdom, nor accept such administrative responsibilities as would attach to any central authority which might purport to act in control of the local arrangements for those purposes; but that the Council would willingly, if so desired, provide examination rules for the assistance of administrative authorities, local or central, which might be appointed for the purposes of the law."

Dr. HUMPHRY said that he should like to propose an amendment to that resolution. It was evident that if rules for the training of midwives were to be drawn up at all, some body must take the initiative, and that unless the Council undertook it, he did not see who there was that could do so, as that there was not at present any public mechanism whatever for the education and examination of midwives. He therefore moved, "That section 1 of clause 24, be in substance approved."

Mr. TEALE seconded this.

Dr. FERGUS said that having regard to the resolutions they had passed with respect to drawing up rules for examination of medical men and of dentists, he did not think that they could consistently propose to initiate rules for the education of midwives.

Dr. WOOD said that it should be remembered that the clauses in the Bill relating to midwives had been inserted on their own recommendation, and he thought they would hardly be acting consistently if they refused to be instrumental in carrying out their own suggestions.

Sir WILLIAM GULL said that he thought action ought to originate from the periphery at the local authorities. That as yet there were no examination boards for which to frame rules, and he doubted that they would be able to call such boards into existence. He did not think that they adequately realised the magnitude of the duties they would thus undertake.

Dr. ROLLESTON said it was plain that there must be a start somewhere, and that he did not think that there was any other authority so well fitted to make it as the Council. To take the initiative was all that was required of them. He did not think that this would throw such an amount of labour on their shoulders as they appeared to think. At any rate they were well paid for their services, and he thought they should take care not to lay themselves open to the imputation of casting about how not to do it, but of being anxious to be of as much service as possible to the profession and the public.

Dr. HUMPHRY, in reply, pointed out that by taking the initiative the Council would have the power of instituting a scheme such as they knew they were capable of carrying into effect. In reply to Dr. Fergus, he would observe that the cases of the dentists and midwives were not parallel; for the former there was already a system of training and examinations, while the needs of the latter were as yet without such provision. On this account he denied that the Council in any way laid itself open to the charge of inconsistency; it decided to confine itself to supervision of the one, while it undertook to initiate rules for the other.

The amendment was then put and carried, and having been put as a substantive motion, was agreed to.

The Council then resumed for the transaction of more formal business, but on the completion of this, again went into committee on the Bill.

Section 2, clause 24, was in substance approved.

Section 3.—Dr. HUMPHRY pointed out that this section contained the expression "The midwives' register," evidently written under the idea that there would be a central register for midwives. Here he thought was the point where the shoe pinched too hardly. Such an enactment would throw a great amount of work on the Council, which was, in his opinion, too important and too expensive a machinery to be used for such a purpose. Local registers would meet all the requirements of the case. The case was different from that of the medical register. A medical man was a much more important unit of the community, and it was important that all the world should know where to find him; but no one in Yorkshire could possibly be interested in who were the midwives of Devonshire. Such registers could be kept by the various local authorities, without any great additional expense or machinery.

It was then moved by Dr. HUMPHRY, seconded by Sir JAMES PAGET, and agreed to :—

"That in the opinion of this Council it is not necessary that a central Register of Midwives should be kept, but that there should be local registers, and that the duty of keeping them should devolve upon the authorities having power of government in the several places in which the examinations are conducted."

Mr. MACNAMARA said that throughout clause 4 the words to practice "midwifery" were repeatedly used with respect to the practice of midwives. Now "midwifery" was, in his opinion, a word of much too wide a scope to be applied to such a purpose. Even at present, as was well known, these women were often in the habit of taking a great deal too much upon themselves, and if they allowed the Act to pass as it stood they would be able to plead legal permission to use instruments, and to do other things which they were in no way qualified to attempt.

It was therefore moved by Mr. MACNAMARA, seconded by Dr. AQUILLA SMITH, and agreed to :—

"That the word 'midwifery' in lines 2 and 5 of section 3 of clause 24 be changed to 'as a midwife,' and that the same change be also made elsewhere throughout the Bill."

Moved by Dr. HUMPHRY, seconded by Sir JAMES PAGET, and agreed to :—

"That sections 3 and 4 of clause 24 be modified in accordance with the foregoing resolution, and that it be provided that a certificate of good character be required in the case of those who present themselves for examination or registration."

Moved by Dr. HUMPHRY, seconded by Sir JAMES PAGET, and agreed to :—

"That section 5 of clause 24 be in substance approved."

Moved by Dr. ROLLESTON, seconded by Sir JAMES PAGET, and agreed to :—

"That the following be in substance an addition to section 5 of clause 24 :—'Persons not upon such a Register shall not be eligible for public appointments as midwives.'"

Moved by Dr. HUMPHRY, seconded by Sir JAMES PAGET, and agreed to :—

"That section 6 of clause 24 of the Bill, to the end of the sub-section (1), be in substance approved."

Little or no discussion attended the proposition and passing of the above resolutions.

With respect to sub-section 2 of section 6,

Sir WILLIAM GULL pointed out that a sort of central register might without any trouble or expense be provided by causing a copy of the local registers to be annually forwarded to the Council.

It was then moved by Sir WILLIAM GULL, seconded by Dr. ROLLESTON, and agreed to :—

"That, instead of sub-section 2 of section 6 of clause 24, the following be substituted :—

"The Register of Midwives shall from time to time, and at least once a year, be printed, published, and sold in the several districts of the United Kingdom, as directed by the General Medical Council from time to time and that copies of these Registers shall be forwarded to the Medical Council on the first of January in each year."

Moved by Dr. HUMPHRY, seconded by Sir JAMES PAGET, and agreed to :—

"That lines 28 to 40 of section 6 of clause 24 be in substance approved."

Moved by Dr. HUMPHRY, seconded by Sir JAMES PAGET, and agreed to :—

"That with reference to section 6 of clause 24 the Council is of opinion that the duty of prosecuting under this clause should devolve upon the local authorities specified under section 5."

Moved by Dr. ANDREW WOOD, seconded by Dr. AQUILLA SMITH, and agreed to :—

"That clauses 25, 26, 27, 28, 29, 30, 31, 32, 33, 34 be in substance approved."

Clause 22, which contains the new enactments with respect to unregistered persons, and the penalties to be imposed on persons falsely assuming registrable titles then came on for consideration.

Sir JAMES PAGET said that he was by no means clear as to the scope and meaning of the various paragraphs of this clause. He should like to know whether or not under it, a registered person using the M.D. of a foreign university, or an M.B. calling himself doctor, could be prosecuted. He, therefore, moved that the attention of the draughtsman should be drawn to this clause, with a view to its being made more definite. This was agreed to.

Dr. TURNER objected to the medical authorities being made prosecuting bodies, and it was determined to also draw the draughtsman's attention to the sixth paragraph. After a short discussion, it was decided, in view of the large number of delicate questions involved in, and the obscurities of this clause, and remembering the small amount of time that was left of the session, that it would be best to refer the consideration of this clause to the executive committee.

The Council then adjourned.

SEVENTH DAY.—DEBATE ON THE MEDICAL ACTS' AMENDMENT BILL—(*continued*).

The minutes of the preceding meeting having been read and confirmed,

The Council went into committee on the Bill.

The PRESIDENT said that they had received the deputation of the Medical Reform Committee that morning, and that the

point on which Dr. Waters had put most stress, was the opinion they held that a change should be made in the constitution of the Council. That it should consist of one quarter representatives of the profession, one quarter Crown nominees, and one half representatives of the corporations. The total number of the Council Dr. Waters does not think important. He thought it right to add that no opinion had been expressed in answer to the representatives of the deputation, as the Council had not given them any power to do so.

Dr. ROLLESTON said that he had two resolutions to propose with regard to the clauses 14 & 20, which referred to the education of women. The substance of those resolutions was, that there should be a separate register, separate examination, and separate training for women.

Dr. WOOD said that he thought that before they said anything about these motions, they ought to be clear as to what the Act meant.

Dr. ROLLESTON said that if the State left them their independence of action, they would expect that they should obey the voice of the public, and that the public did demand that examination rules should be provided for women, that there was no way of getting out of it, and that he did not think that permissive legislation would meet the case.

Sir JAMES PAGET said that there was a feeling that this Act would make the position of the women worse. That now having obtained the qualification open to them, they were able to be placed on the register. At present, there was no surgical authority which was willing to examine women, and hence that women would no longer be able to be placed on the register after double qualification was made compulsory, and he thought this could not be intended, but that if the Act were read closely, it would be seen that it would be the duty of the Council to force all the surgical authorities to provide for the examination of women.

Dr. HUMPHRY said that the clauses on this subject were very involved, but that he did not think that the Act would bear such a construction as that which Sir James Pajet had placed on it, because subsection 4a, stated that the rules should not compel any medical authorities to do so. He, therefore, moved that section 4, be approved provided that a Conjoint Scheme be established. (Cries of no ! no ! oh ! oh !)

Mr. SIMON said that these sections were most complicated, and contained pitfall after pitfall. He thought that on this account, they should state as plainly as possible their opinion with regard to the medical training and registration of women, apart from the wording of the clauses altogether.

Dr. WOOD said that as far as the clauses stood, they were very grateful to him, as according to it, no woman, as Sir James Paget had shown, could be in futute registered He, indeed, thought that a consummation devoutly to be wished, but he feared that matters had gone too far for such a happy condition of things to be brought about.

Dr. ROLLESTON said that he thought that the case must be met by making it necessary for any Conjoint Scheme to provide for the examination of women. That whatever people might say, it was necessary to provide both for the examination of women, and for conjoint examinations.

Dr. ROLLESTON then proposed that the examination rules shall provide for the examination of women.

The motion was agreed to.

Mr. SIMON suggested they should qualify this by moving, "but with such distinctions as are necessary in the different cases of men and women."

Sir DOMINIC CORRIGAN wanted to know what those distinctions might be ?

Mr. SIMON said that that was not for their present consideration.

Dr. ROLLESTON said that he knew he should be abused by both sides, and on that account felt sure that he was right. And he would, therefore, propose as an amendment "That those rules must provide for the separate education, separate examination, and separate registration of women."

Mr. MACNAMARA said that he thought it most objectionable that a woman should not be examined or be liable to examination in all branches of the profession. As soon as she was placed on the register she would be able to practise all branches of the profession. He did not think that women were intellectually unfit, considering the eminence they had attained in literature ; but he thought that the profession was such that their modesty ought to prevent their joining it – that the very elements appeared to object to it.

Dr. ROLLESTON then read a motion to the effect that he had mentioned.

Mr. MACNAMARA proposed as an amendment, "That the Council did not approve of sub-section *b* of 4 of 14."

Sir J. PAGET said that he was very anxious that the Act should pass, and he therefore thought that they should be very cautious lest they should provoke strong opposition from any quarter.

Sir W. GULL said that he thought that they should point out to the Lord President that they had no power to carry out the provisions of the Bill. Where was the good of their framing rules when no authority would adopt them.

Dr. ROLLESTON replied that he could not help arguing on the hypothesis that they would have a Conjoint Scheme.

Dr. TURNER said he objected to the use of the term "obligation" in sub-section *a* 4.

Dr. ROLLESTON then proposed as an amendment in subsection *a* that they should substitute for (*a* 4) "That no medical authority who, at the passing of this Act, has not granted qualifications to women shall be compelled to admit women to examination."

Sir JAMES PAGET said that they must not shut their eyes to the fact that if this Act passed, and no surgical authority was to be compelled to examine women, women would evidently be no longer able to be registered. Would Dr. Rolleston tell him how a woman was to get on the register under the Act.

Dr. ROLLESTON replied that he could not do that, but that he could not conceive a Conjoint Scheme that did not provide for the examination of women, and that he considered that a Conjoint Scheme was inevitable.

Dr. Rolleston's motion was then put and carried.

The addition of a memorandum was then proposed by Sir WILLIAM GULL, "to direct attention to the want of power on the part of the Council to carry out the conditions of clause 14.

This was also passed.

Dr. ROLLESTON then proposed, "That it shall be in the power of the Council to frame rules for a board for the examination of women."

This resolution was agreed to.

Dr. ROLLESTON then proposed, "That any Conjoint Scheme that may be proposed shall provide for the examination of women."

The PRESIDENT pointed out that this would be an almost insuperable obstacle to Conjoint Schemes. And the motion hence fell through.

Mr. MACNAMARA then proposed, "That sub-section (*b* 4) be omitted."

This was carried.

Dr. ROLLESTON then proposed, "That for it should be substituted clauses providing for separate education, examination, and registration of women.'

Dr. HUMPHRY said that he thought that this was hardly a subject for legislation. That it would be quite as reasonable for the State to provide for the separate education of boys and girls. He thought that this should be left to the judgment of the various corporations. He strongly doubted that any such serious consequences would be likely to happen even if male and female students were educated together. He had seen male and female students working very well together at the Moorfields Infirmary, and he had had women as well as men at his own lectures, and he had observed nothing beyond a healthy rivalry ; and he thought that it would be quite sufficient to trust to the good feeling and honour of English men and English women.

Mr. MACNAMARA said that he did not think that any such legislation was necessary, and that it would put a new bar to the admission of women to the profession, as it would necessitate separate lectures on all subjects.

The motion was then put and carried separately with regard to all three clauses of the motion.

With regard to a separation of the registration of women, the names of those who voted were called for, and resulted in 10 for, 8 against.

Mr. SIMON then proposed "such separation of names not to involve any difference of legal rights." The motion was carried.

Section 5 was in substance approved. Sections 6 and 7 were also in substance approved, noting that they should be brought into conformity with their previous resolution with regard to the framing of rules. Section 8 was in substance approved.

Mr. MACNAMARA said that with regard to clause 33,

taken in connection with clause 4, he should like to point out that the registrar was defined as the registrar of the General Medical Council, and that these clauses taken together, would require the register for Ireland, and the £5 to be centralised in London. This might be accidental or intentional. If it were intentional, he should have to say more on the subject. If there was no intention of changing the law with regard to the local registers, there could be no objection on the part of the Council to drawing attention to the effect of the clause, and he therefore proposed a motion drawing the attention of the draughtsman to the effects of the clauses, and suggesting that they should be brought into conformity with the clauses on the subject, in the Act at present in force.

This was agreed to.

Sir DOMINIC CORRIGAN then proposed his amendment of clause 14, section 2 :—"The examination rules shall not require a candidate to adopt the practice of any particular theory of medicine or surgery;" and added that he would wish to cut out the words "refrain from adopting." He mentioned instances in which grave consequences had happened from homœopaths and others neglecting to perform the most necessary measures.

Sir W. GULL said that he thought that no Government would consent to removing such words as those.

The motion was negatived.

Section 15 :—Dr. HUMPHRY pointed out that this clause did not give any power of withdrawal from conjoint boards on the part of any authority. He therefore proposed that words should be inserted to the effect that any authority might withdraw from such a combination in the event of there not being an examining board for each division of the country, as recommended in the previous resolution of the Council.

This motion was carried. The section was otherwise approved.

Clause 16 was in substance approved.

Clause 17 :—Dr. PITMAN said that he would wish to point out by this clause, any woman passing a conjoint examination, would be entitled to all of the qualifications of the combined authorities, and that he feared that this would be fatal to the adoption of any Conjoint Scheme.

It was determined to consider this question while on section 20. With this proviso the clause was in substance approved.

Clause 18.—In substance approved.

Clause 19.—Mr. SIMON suggested that the attention of the draughtsman should be drawn to the extremely wide bearing of the words, "such information."

Clause 20.—Mr. SIMON wished to make an extension of the powers under this motion to enable any authority or combined authorities to institute new diplomas *specially* for women, which should be registrable under the Act.

DR. PITMAN said that he should like it to be clear that no authority should be obliged by a conjoint scheme to give its degrees to women.

Mr. SIMON proposed an amendment, "That after the words 'both sexes,' there be inserted 'with distinction,' if considered necessary, between the diplomas of men and women.

Dr. ROLLESTON said that he could in no way support such a resolution.

The amendment was put and lost.

Clause 21 was in substance adopted.

This completed the consideration of the Medical Act.

The council then resumed.

THE PROSECUTION OF UNQUALIFIED PRACTITIONERS.

Sir DOMINIC CORRIGAN then proposed the following motion :—

"That while the Council (as exressed in Resolution 7, on p. 189 of vol. xiv of the minutes) cannot undertake the duty of prosecuting unqualified practitioners, they, nevertheless, think it their duty to draw the attention of the Local Government Board of England to a practice, which it would appear exists in England, of practitioners in charge of medical relief districts employing unqualified assistants to act for them in the treatment of medical and midwifery cases, tending to the detriment of the public, and other evils; and they would suggest to the Local Government Board of England the consideration of the rule in Ireland, that no medical officer in charge of any dispensary district is permitted to have a substitute to perform his duties unless for a limited time, and unless such substitute is fully qualified to the satisfaction of the Dispensary Board, and with the sanction of the Local Government Board."

The motion was agreed to.

The session of the Council then concluded, but it was considered probable that there would be a second short session shortly before the 20th May.

Original Communications.

THE CAUSES AND COURSE OF DISEASES OF THE HEART, WITH SPECIAL REFERENCE TO PREVENTION AND TREATMENT. (a)

A Course of Lectures delivered at the WEST LONDON HOSPITAL.

By J. MILNER FOTHERGILL, M.D., M.R.C.P.,
Assistant Physician to the Hospital, and to the City of London Hospital for Diseases of the Chest, Victoria Park.

LECTURE III.—THE GOUTY HEART AND FATTY DEGENERATION.

THE lecturer commenced by saying that the relations of the gouty heart to fatty degeneration in its later stages justified their being discussed together. The term, gouty heart, suggested at once the origin of the changes, and the relations of these changes to alterations in the kidneys. A gouty condition might be produced by defective oxidising processes, as well as by a superfluity of food. In those hereditarily gouty the most ascetic fare would scarcely protect from gout in some of its forms. The retrograde product of nitrogenised material which had the greatest tendency to linger in the system was uric or lithic acid; hence the terms "lithiasis" and "lithæmia," had been employed to indicate a condition where there was excess of such waste in the system. Some persons with lithiasis seemed peculiarly prone to disease in their circulatory system. Dr. Johnson had observed a thickening of the muscular walls of the arterioles in cirrhosis of the kidneys: and Sir Wm. Gull and Dr. Sutton had described an arterio-capillary fibrosis, associated with renal changes; probably each saw a part of a great pathological process, which must be still further studied before it can be seen in anything like completeness.

The first step in the chain of morbid processes is the presence of lithic acid, or other waste, in the blood in excess. Such a condition is not confined to ruddy complexioned persons, though almost certainly present in them. The effect of this is to set up contraction of the tiny arterioles, and so to obstruct the flow of blood through them, so that the blood is damned up in the arteries, and thus the arterial tension is heightened. This offers an obstruction to the onward flow of the blood out of the ventricle in its contraction, and this leads, as was seen in the last lecture, to hypertrophy of the muscular walls. By the hypertrophy of the heart, and hypertrophy of the muscular walls of the arterioles, the state of high blood pressure within the arteries is maintained: and this over-distension of them in time leads to atheroma of them. The progress may be very slow and extend over many years, yet it steadily progresses. At last changes are set up in the walls of the heart, and cardiac failure follows. The pathological process in these cases explains the signs and symptoms found during its progress. The muscular hypertrophy of the heart might be long maintained, but the changes in the arteries necessarily lead to decay of the muscular walls in time. The development of connective tissue in the arterial walls leads to loss of elasticity, and consequently of the arterial rebound after distension by the ventricular systole. This change is often pronounced in the coronary vessels, placed at the base of the aortic column, and so exposed to the full force of the aortic rebound. Changes, too, are often well marked in the thin walls of arteries within the encephalon, and rupture of one of them, or true apoplexy, is one of the chief dangers of this condition of hypertrophied ventricle and contracted arterioles. In many stalwart families there is a history of unbroken health till

(a) Abstract of Lecture III.

middle age, then apoplexy in some members of the family, and sudden death from heart failure in those who live till old age.

The manner in which these changes in the heart walls are brought about, he said, were as follows :—

The arteries becoming less elastic the coronary vessels, which are filled by the aortic rebound, are no longer sufficiently supplied with blood ; while the current is broken by the tortuous windings of the coronary arteries. This imperfect blood supply leads, in time, to fatty degeneration of the muscular walls, but usually the process is a long and chronic one, not recognised till almost the final stages are reached. At last, however, the necrosis of the muscular fibrillæ reach that point when dilatation sets in, no longer arrested by hypertrophy, and the evidences of cardiac failure are manifested. At other times there is no dilatation, and the heart retains its normal shape. In the first case, we have dropsy, dyspnœa, &c. ; in the other, there is merely general failure of the powers, with great liability to sudden death. Indeed, the matter for surprise is, that sudden death does not more frequently occur than it does, and at an earlier period too. In such sudden death the end is brought about by some sudden increase of the blood pressure within the heart, as from quick effort to catch a train or an omnibus, the weakened walls are distended in diastole, the ventricle fails to contract, and all is over.

The relations of angina pectoris to this sudden stoppage of the heart in diastole, are very interesting, *i.e.*, true angina, not merely neurosal angina. It is now known that in true angina there is a rise, not a fall of blood pressure in the arteries ; the heart is embarrassed and the ventricle contracts with difficulty, the pressure within it is increased, and there is danger of it at last ceasing in diastole. As long as the heart walls are structurally sound, severe attacks of angina are survived and recovered from ; but when fatty degeneration is established a fatal result often follows. The starting point of angina is sudden contraction of the arterioles, the arteries become hard and tense, and then the heart is embarrassed. The inhalation of nitrite of amyl which dilates the arterioles has been found to give immediate relief. When the arterioles are dilated, then the blood pressure in the arteries is lessened, and the heart relieved. These sudden contractions of the arterioles are fraught with the greatest danger to life when the heart walls are undermined by fatty degeneration.

When, from imperfect nutrition, the heart walls commence to decay, at first fat granules are deposited in the germinal matter and then through the muscular structure. At first the striæ are lost, and ultimately the muscular fibrilla is converted into a string of beads of fat within the sarcolemma. This necrobiotic change is not spread evenly through the heart : advancedly decayed fibrillæ are found alongside fairly sound fibres ; and some localised areas are more affected than others. This last is probably due to some arterial twigs being more diseased than others. Or one ventricle may be more affected than another, as from an atheromatous plate over its orifice. In advanced disease the heart has a dead-leaf hue about it, and the finger can readily be thrust through the walls of the ventricles. Such is the end of an hypertrophied heart if the patient survives long enough.

At times fatty degeneration of the heart is found with a sustained pyrexia, with phosphorus poisoning, or pernicious anæmia. It is also found in elderly persons at times, not being the consequence of the morbid changes detailed above : but rather of a splitting up of the tissues as a species of senile change. Michael Foster says that in advanced life "we see a disposition on the part of protoplasm to fall back upon the easier task of forming fat, rather than to carry on the arduous duty of manufacturing new material like itself ; everywhere, almost, we see a tendency to the replacement of a structured matrix by a deposit of amorphous material." The question which arises is this, "Is this condition one permitting of repair ?" And if so, can we do anything therapeutically to aid the natural efforts ? We know that a condition of fatty degeneration occurs in the uterus after delivery, in the muscles of a broken thigh, and even in the heart itself after fevers. It also, probably, occurs as a more chronic process with some women at the menopause, and it seems in a certain number of them to be recovered from. It would seem probable that, in such cases to increase the oxidising powers by plenty of fresh air, without, however, too much exercise, and by a dietary largely free from hydro-carbons, it is possible to remove the fatty *débris* and lay down new material. Such a plan would be aided materially by a course of iron, which increases the amount of hæmoglobin, and with it the oxidising processes of the body. Some digitalis to maintain the action of the fibres remaining sound is also indicated. The plan is worth a trial, and in some cases seems to have succeeded.

The lecturer then proceeded to the subject of the treatment of the gouty heart. He pointed out how a knowledge of pathological processes could direct our therapeutic measures, and teach us how to prevent or retard what could not be cured when established. He divided the treatment into that of the first stage, viz., hypertrophy, and that of the second, viz., heart failure. The treatment of the two varies much. As to the first stage it was necessary to reduce the bulk of nitrogenised waste from which the troubles commenced, as the first step ; and to attain this the patient should be put on a dietary which contained but a small proportion of albumenoids, just such an amount as would meet tissue repair, and no more. Gouty people do not require, as some other persons do, large quantities of animal food. A non-nitrogenised dietary lowers the arterial blood-pressure, and with that its consequences. Even in albuminuria it was not well to give albumenoids freely. Such a dietary lessened the chronic high blood-pressure, and also kept off the acute conditions of angina. A lobster salad was the typical dish of a gouty person with a good digestion. Potash or lithia, which form soluble salts with uric acid, should be given, with colchicum or buchu. If found too depressant, a little nux vomica might be added. They should be taken before meals, with a draught of water. Iron and digitalis are rarely indicated in the first stage, except where the cardiac hypertrophy is mixed with dilatation. But when the heart is failing then they are called for imperatively. They should be given steadily away, week after week, and if necessary, year after year, without fear of any accumulative action. Digitalis does not lurk about the tissues to do mischief, as it were through malice. When there are attacks of uræmic dyspnœa, strychnia or belladonna, as stimulants to the respiratory centre, are indicated. Exercise is good as long as the heart is sound. In the dropsy of the gouty heart tapping is more useful than in pure heart cases.

AN ANALYSIS OF FORTY CASES OF CLUB-FOOT. (*a*)

By ROBT. LAFAYETTE SWAN, F.R.C.S., L.K.Q.C.P.I.
Surgeon to the Dublin Orthopædic Hospital ; Member, Court of Examiners, Royal College of Surgeons ; late Lecturer on Anatomy, Steeven's Hospital.

In the following paper I omit all reference to distortions connected with traumatic causes. Also to that large and very important class of deformities which are dependent on general conditions ; or centric lesions—their treatment, whether associated with chorea, paralysis, hysteria, or any allied neuroses, opening a far wider domain of therapeutics than those varieties of distortions for which the surgeon finds mechanical appliances chiefly remedial. I have tabulated forty cases typical of the varieties of club-foot usually met with, which have come under my own observation.

The literature of club-foot is undoubtedly profuse, and there are in existence numerous treatises which enumerate more or less plainly the errors to be avoided, and the practice to be pursued. In spite, however, of this fact I think most surgeons will admit that numerous examples

(*a*) Read before the Surgical Society, March 29.

are seen of want of success in the treatment of the commonest varieties of talipes, which no other branch of surgery presents. As in the field the soldier, from successive defeats, learns how at length to conquer, so the surgeon, from his own failures, as well as from those of others, should follow those signs which mark the path to final triumph. I shall endeavour, from facts in my possession, to state briefly the reasons for failure in the management of the varieties of this deformity.

Equino varus being the most usual form of club-foot met with, offers the greatest number of uncured results. Of the forty cases which I have classified, twenty-six belong to this affection, of which eighteen had been previously under treatment; amply indicated by cicatrices of incisions, or of sloughs from the pressure of apparatus, or in occasional instances from the statements of the parents, where extension without leaving a mark had been unsuccessfully applied.

The causes which led to want of success in those cases, may, I think, be placed under three heads.

1st. Removal of forces producing deformity in improper order.

2nd. Transfixion of tendons, or omission to divide a tendon which should have been divided.

3rd. Improper application of extension. Deficient time allotted to the subsequent treatment. The application of improper retaining apparatus.

Despite the teachings of Little, Adams, Brodhurst, and the majority of surgeons at the present time, which show definitely the principle of selection in order of the tendons to be divided, it is of common occurrence to observe in aggravated equino varus, the tendo Achillis first divided, or in conjunction with the tibials, or with the anterior tibial alone. This practically adds to the difficulty of treating the varus; the entire foot rotating at the tibial tarsal, instead of at the median tarsal joint, the true situation of rotary varus.

The plantar fascia is frequently seen divided simultaneously, or subsequent to the division of the tendo Achillis. As in the great majority of slight cases, and in every instance of exaggerated contraction of the fascia, it requires a greater and more prolonged force to unfold the plantar arch than to remedy the equinus; and by the division of the tendo Achillis the fixed point from which to make extension is lost, the difficulty in treatment is increased, or calcaneous is the result.

In six of the eighteen cases enumerated, the tendo Achillis and anterior tibial had been divided in conjunction; in three, the tendo Achillis and plantar fascia together; in four, the tendo Achillis alone.

Although impossible to demonstrate the transfixion of a tendon, yet we may, I think, with some certainty, draw such an inference from the following facts: 1st. The influence of point pressure on the tendon below the site of attempted division, which will produce spasmodic contraction of the corresponding muscle. 2nd. In such a case extension is performed slowly, and with difficulty, followed by rapid recontraction, when treatment has been stopped; the resumption of the deformed position with a spring when extension with the hand is suddenly withdrawn.

If old cases are seen where extension seems limited at the situation of the cicatrix, where the tendon is adherent to the adjacent structures, and no elongation of a new tissue appears to have been produced at the time of treatment, the presumption is that the tendon was transfixed. In connection with the second class of signs of transfixion above alluded to, I may mention that a case of equino varus, recently under my own treatment, was proceeding unsatisfactorily, when on one occasion, while manipulating the foot, some undivided fibres of the posterior tibial tendon snapped across, after which the unfavourable symptoms vanished. It is not difficult to understand how transfixion of tendons may occur. The fear of wounding the anterior tibial vessels may lead the surgeon to cut very close to the external edge of the tendon. Its small size, and the difficulty of feeling this structure in an infant, with the variation from its normal situation which generally exists, likewise add to the liability to the accident. Failing to get the tenetome into the sheaths between the posterior tibial tendon and the bone, is necessarily a cause of the accident in this situation.

In but two cases of the eighteen was the posterior tibial tendon divided; all of them required such section. I have endeavoured in as many instances as possible to discover the cause of this omission. The answers I have obtained were the following:—1st. That the tendon could not be discovered. 2nd. The fear of wounding the posterior tibial artery. 3rd. That it was in many cases unnecessary. The plain rules laid down for finding its situation, render it unnecessary to feel the tendon, and with some care the posterior tibial artery may be avoided. Mr. Adams disposes of this objection by stating that he would prefer wounding the artery to missing the tendon. I have myself on more than one occasion unskilfully divided the artery, but fortunately no bad result followed. In those cases I made the division of the tendon certain. I have no doubt, whatever, that to effect a perfect cure of true rotary varus, a section of the posterior tibial tendon is essential.

The third and most important series of obstacles to success in the treatment of equino varus, are: the improper application of extension; deficient time allotted to the subsequent treatment; the application of improper retaining apparatus.

I shall first consider the improper application of extension, and include as its most common unfortunate results, sloughing, from too long continued pressure on projecting points, and the consequent interruption to treatment; the induction of paralysis of a muscle, or series of muscles, from too rapid extension. These events may occur from more than one cause. The surgeon, from urgent demands on his time, or from the neglect of the parents to bring the child for treatment on the appointed day, may omit to remove the extending appliance sufficiently often; or in large general hospitals, this portion of the treatment is not infrequently consigned to a pupil whose zeal, untempered by experience, most commonly defeats the object he seeks to attain. This fertile source of failure has been forcibly alluded to by Mr. Little. Five of the eighteen tabulated cases presented, when admitted to hospital, marks of sloughs of the integuments; in two instances, unhealed. In one, calcaneus, with paralysis of the posterior muscles of the leg, had been induced after section of the tendo Achillis, and too rapid extension.

There are many circumstances from under the control of the surgeon which curtail the time given to the treatment of club-foot. The patient—at least, among the poorer classes—is usually removed from under the surgeon's care far too soon. Apathy, or pressing duties, prevent the parents from following the directions given, and the result is a partial relapse, even in those cases which at first seemed very favourable.

A tendency to inversion of the toes, after the tendinous and fascial structures have been fully extended, is commonly noticed. This is so usual that I have endeavoured to ascertain the cause. The circumstances which induce it may, I think, be classified into passive and active. *Passive*—Incomplete contractile power of the peronei, or extensor digitorum muscles. Absence of the normal forces which retain *in situ* the articular surfaces between the calcis-cuboid, fourth and fifth metatarsal bones, by the structural lengthening of the following ligaments: Deep portion of the long plantar ligament; dorsal calcaneo cuboid; cuboids metatarsal ligaments passing to the fourth and fifth metatarsal bones. *Active*—The rapid re-contraction of the integumental structures at the inner side of the foot, aided by the subsequent and slower contraction of the muscles which have no opposing agency. I have repeatedly observed this to occur, and it may be demonstrated by allowing a foot, apparently cured of equino varus, to remain for some days without manipulation, or any other extending treatment. On everting the toes at the end of

that time, it will be seen that the capillaries of a certain patch of integument are entirely deprived of blood, owing to the strain on that structure. A few days' continued treatment will suffice to re-extend this tissue, to be followed, on its intermission, by a relapse. The cure of equino varus must therefore be considered incomplete when there is an imperfect balance between the muscular forces, causing the deformity, and those opposing its production; while the ligaments above enumerated are so lengthened as to admit of an abnormal separation between the bones they unite. If the patient be arrived at that age when he can co-operate with the surgeon, it must expedite the process, but practically it can be of no limited duration.

The application of improper adjusting apparatus is one of the most frequent causes of eventual disappointment in the treatment of equino varus. There is nothing more easy than to conceal a very distorted foot in a boot which, giving the member a shapely appearance, will satisfy the parents for the time, and even seems sometimes to content the surgeon.

Examples of this nature are daily met with, in which the mechanical arrangements are not at all adapted to the purpose required. A very common form of appliance in the treatment of equino varus, is one which, in the endeavour to remedy the commonly existing inversion of the toes, rotates the entire limb, more or less, from the hip-joint. In the great majority of cases, this is entirely unnecessary, and when so, is injurious, being deceptively efficacious.

I have seen very aggravated varus assume a natural position—apparently—when the entire limb has been thus rotated outwards. The boot which I show, and I have—except in a few rare cases in which rotation inward of the entire limb existed—invariably used with great satisfaction, as I consider it applies extension to the real cause of the inversion, and is, in addition, not costly, and simple in its construction. It consists of an ordinary laced boot (fig. 4), with a rule joint at the junction of the heel and sole, with an inside stem and bar passing round, and terminating in a spring, which acts at pleasure on the anterior segment of the foot.

I am very much in favour of a treatment which, I observe from some reported cases, has been resorted to by Mr. Lambert Ormsby in the treatment of club-foot. It was first suggested to me by the facility of application of Sayre's plaster bandage in spinal curvature, which—the foot being maintained in position by an assistant—forms a perfect mould for the member. By adapting a piece of padded lead-plate or leather to the sole (the accompanying illustrations, Nos. 1, 2, 3, exemplify), the flexion of the toes which sometimes exists is overcome, and the patient soon learns to walk in the temporary boot so constructed, a matter of great importance in the development of the muscles of the limb. By this means an expensive Scarpa's shoe may often be dispensed with. I have treated the case, almost altogether by this means, with a good deal of success. The use of plaster of Paris in the treatment of talipes, is not by any means new, having been described by M. Guerin—although somewhat differently applied—as early as 1836.

Ten of the forty cases were affected with valgus; five of the congenital, and five of the acquired or spurious, variety. The latter were selected from a very large number of that class. The congenital cases varied from a minor to a very aggravated degree of the affection, with convexity of the sole of the boot. In none of those cases was tenotomy necessary. Manipulation and retention of the foot in its natural position sufficed for all. In those cases associated with calcaneus, the development and contraction of the gastro-cnemius, completed and maintained the cure. In cases of this kind I found the plaster bandage a very efficient splint. A small pad, to restore the arch of the foot, will be useful. In whatever retaining apparatus the foot be placed, it should be removed daily for the purpose of manipulation, which is of the utmost importance.

Acquired valgus appears to be a very common affection in individuals whose employment necessitates standing for a length of time. Hence grocers' assistants, shop girls, &c., seem often so troubled. It is usual to see one foot alone so engaged, or the other in a minor degree. This may be explained by the habit of resting the body on one member, and thus stretching the ligamentous structures of the arch. On examining the affected foot at an early stage, it is not easy to mark any deviation from the normal standard. By causing the patient to stand on each foot alternately, it will be found that the affected arch is shorter than its fellow, or absent altogether, as the valgus is minor or complete. By colouring a flat surface with red or blue chalk, and making the person stand thereon, a correct estimate of the diminution of the arch may be formed. The pain which accompanies this affection will be found to assume two distinct characters. 1st. A gnawing, dull sensation, referrable to the instep, aggravated by exertion or continuous standing, and alleviated by rest. 2nd. Pain of a lancinating description; so violent as occasionally to completely deprive the patient of the power of locomotion. It will be seen that the severity of the suffering does not always increase in proportion to the development of the distortion. These symptoms indicate two distinct conditions. The first variety, a relaxation of the tibialis posticus muscle, lengthening of the inferior calcaneo scaphoid ligament; falling of the arch of the foot; approximation of a portion of the enarthrodial joint formed in part by the above-named ligament to the ground, and subacute inflammation thereof with its consequences. The second, undue tension or stretching of the plantar nerve. I have lately had an opportunity, through the kindness of my friend, Dr. John Barker, of examining a specimen of aggravated valgus, which was associated with, if not the result of, rheumatic arthritis. The partially ossified condition of the cartilages covering the astragalo scaphoid joint was well seen.

The connection that appears to exist between acquired valgus and lateral spinal curvature is remarkable, especially in young females. It no doubt, in a great degree, is due to the formation of a series of compensatory curves; but there may exist a unity of diathesis as a powerful pre-disposing element. The accompanying photo-lithograph (fig. 5) represents a case which illustrated this connection very plainly.

The following cases illustrate that a mistake in diagnosis may be made in this affection:—

J. R., æt. 27, grocer's assistant, came to hospital, June 23rd, 1877. Complained of an aching pain in the left foot after standing for any length of time, or walking a short distance. Has been in consequence in a state of great discomfort for more than two years, and has gradually become worse. He has been under surgical treatment on three occasions, in the country and in Dublin. Has been blistered and leeched on the foot, and has used various liniments without benefit. Has lately worn a tight bandage round the instep, which affords him some relief. On examining the foot off the ground, no very marked deviation from its normal condition could be observed; but on placing it on the ground, and directing him to bear his weight thereon equally with the other, a marked depression of the arch of the foot was clearly seen. Ordered a laced boot with a convex sole plate, to restore the natural size of the plantar arch.

July 4th.—Has been wearing the boot a week with great comfort. Can now pursue his occupation without inconvenience.

J. E., æt. 19, shop girl, was first seen October 2nd, 1877. Has been confined to the house for the past six months, unable to walk to her employment. The left foot found to be the subject of aggravated valgus. The inner malleolus came near the ground on standing, and the arch of the foot was completely lost. The tendons of the peronæus tertius and extensor digitorum were tense, and resisted extension; structural shortening of those muscles had evidently taken place. In the early stage, an almost analogous plan of treatment to that before related was adopted; recently nothing had been attempted. Divided

existing tendons. Ordered a boot with outside stem and broad ankle strap, to draw the inner malleolus outward; a smooth steel sole plate covered with leather to support the arch.

October 17th.—Since the 6th inst., by gradual stretching and manipulation, all resistance to placing the foot in a natural position having been overcome, the boot was applied this day.

From this date, with the exception of having to slightly reduce the size of the sole plate, the patient has had uninterrupted ease.

The remaining four cases comprised two of congenital equinus, and two of calcaneus, and presented no unusual characters.

ON THE VICIOUS SYSTEM OF DRAINAGE PREVALENT IN WEST-END HOUSES. (a)

By THOS. FITZPATRICK, M.D. Dub., M.D. Cantab., M.R.C.P. Lond.,
Physician-Accoucheur to the Western General Dispensary.

(*Continued from page 294.*

In the course of my practice during the last two or three years I have met with a series of cases of zymotic disease so closely associated with a vicious system of drainage in the houses where they occurred that no doubt could be entertained as to the two things holding the relation of cause and effect. That such should be the case is no new discovery, but I think we are always glad to receive here fresh illustrations of even the best established truths in the domain of medical science. What is new, however, and may, perhaps, strike many with surprise, is that those cases occurred in the houses of wealthy persons living in the West-end of town; that the unhealthy state of the drainage in each instance was wholly unsuspected by the occupants, and would have remained so if attention had not been forcibly directed to it by the medical attendant. Out of these cases I have selected four for brief description this evening. One occurred in the house of a nobleman in Mayfair, one in a house excellently situated in Bayswater, and two in different houses in the two principal squares near Hyde Park.

I take the first in order because it is the simplest—the case that occurred in Mayfair. The subject of it was a young footman, æt. 22, who caught typhoid fever from sleeping in the butler's pantry, where he was exposed to the emanations from a sink communicating with a sewer in the front area. He called at my house one evening about 9 o'clock, and complained that he did not feel well. The family with whom he lived had just gone to Ireland, and he was ordered to follow with several other servants the next day. I happily recognised the nature of his illness, and telegraphed to his master that he could not go. The disease subsequently ran its course, a severe one, in St. George's Hospital, and terminated favourably. I had that particular sink rectified by Messrs. Banting, and no other case of zymotic disease has since occurred in the house.

II. The second case that I propose to take is much more interesting and remarkable. The house in which it occurred is one of the best in this neighbourhood, and situated in one of our principal squares. It had been specially prepared at great expense for its present occupier, and the system of drainage, carried out anew by an eminent builder, cost in itself several hundred pounds. Nevertheless, it had not been in possession of the family for more than six months when the youngest child, a fine, healthy little girl, of three years, was suddenly taken ill. The attack began in the middle of the night with a cry of pain, accompanied by a certain hoarseness of voice. The next day at noon the child was suffering from unmistakable croup, and dyspnœa became so aggravated that before midnight a timely operation of tracheotomy was performed. False membranes were subsequently extracted from the trachea; albumen was present in the urine; and the case proceeded to a fatal termination. Of course, we could only regard it as diphtheria, and the question arose how and where it had been acquired. Any source of contagion outside of the house was, by the age and habits of the child, excluded, and therefore the necessary alternative was to investigate the drainage and the drinking water. My attention was first directed to the latter, and an analysis showed that it contained a large proportion of nitrites. The cistern from which the drinking water was supplied to the nursery stood under the floor of an upper room in which the cook slept. It was covered by the floor and a carpet, and completely concealed from view, but the cook, who was ignorant of its existence, frequently perceived a bad smell in her room. On examination this was amply accounted for, for the waste from this cistern was in uninterrupted communication with the soil pipe of the water-closet. Elsewhere throughout the house the same defects were made visible. The waste from the bath room discharged into a drain in the stables, which was a perfect abomination, and so on throughout. But this house exhibited another ingenious perversion of the builder's art which I have not seen parallelled elsewhere, and, as it illustrates, in a simple, striking, and convincing form, the evils to which I have been adverting, I will describe it in detail.

Every kitchen boiler is provided with a cock, which is commonly affected, from some inherent fault in its construction, with a troublesome degree of leakage. To obviate the effects of this unpleasant drip from the boiler a vessel is usually placed upon the floor to catch the falling drops; but in our case the ingenious builder bethought him that he would lay a small drain or pipe from beneath the cock, where its aperture was covered by a grating, to the drain in the area. Now what occurred? The sewer gas entered direct from the main sewer, and completely saturated the water contained in this narrow outlet. The fact that it was so was proved in the following manner. I had the impure water ladled out of the open end of the channel beneath the cock, and replaced by fresh water. The latter was then allowed to stand for fifteen minutes, when it was found to be as foul as that which preceded it, and so on as often as the water was renewed. Thus we have here two important facts illustrated in miniature.—1. The ready access afforded to sewer gas by this slight communication between the kitchen and the sewer. 2. The rapid saturation by sewer gas of a small column of water, and its subsequent escape (as evidenced by the foul smell exhaled) into the atmosphere.

The drainage of this house has been remodelled in the most admirable manner by Mr. Rogers Field, and in the two years that have since elapsed no case of illness attributable to similar causes has occurred.

III. The third case to which I invite your attention is still more remarkable than the last, and, I think, illustrates in a still greater degree the importance of a preliminary investigation of the drainage in cases of continued fever. The house, as I have said, is excellently situated in the best part of Bayswater, and, from the abundance of air and light with which it is surrounded, it presents a most healthful and attractive aspect. The subject of the case was a gentleman, 35 years of age, of good constitution and active habits, who, up to the time of this attack, was in perfect health. He began to be ill on the 30th of June; on the 26th of July he had a sharp relapse; and he was unfit to be moved from his house till the 6th of September. The fever thus lasted altogether seventy days, and it was only after his removal from London that complete defervescence was established.

The first question that arose on all sides when the nature of the disease revealed itself was where it had originated, or how it had been acquired. The patient had been in the habit of taking a swimming bath every morning at some public baths, and, for a time, we suspected that that might be the source of contagion. Each morning, as I came to the hall door, an offensive smell was perceptible, which was attributed to decaying

substances in the adjoining dust-bins. Notice of this fact was sent to the inspector of nuisances, who duly replied that the matter would be investigated, but the nature and result of his investigations remain, to this hour, an inscrutable mystery, and that they were perfectly nugatory will be shown by the sequel. Perhaps some gentleman present, who may understand the sphere of duty of this parish official, will inform us what he ought to have done. Is he invested with the power of discovering a nuisance as a dog discovers truffles—by his nose? And, having found it, is he armed with summary powers for its removal or abatement? In one word, is it of any possible use to invoke his assistance where the sanitary state of adjoining houses is supposed to be at fault, and harmful to the occupants of another house? However, as soon as I had placed my patient in the hands of a physician at Folkestone, and returned to town, I began this investigation for myself. At the rear of the house, opening on an extensive square, or garden, was a spacious balcony, which had been handsomely paved with coloured tiles and shaded by an awning. On a wicker arm-chair, in a corner of the balcony, my patient was accustomed to sit in the summer evenings, while below him, on his left hand was the head of a rain pipe, which communicated directly with the drain in the back yard; and, on his right, the opening of the waste pipe of a cistern, which discharged into the trap of a very foul w.c. From the seat that he habitually occupied he might rest on one of these apertures with his right elbow and touch the other with his left hand. In this house, too, which was the property of the occupier, a considerable sum had been paid only a couple of years previously to a builder on account of the drains. Yet, on examination, what did we find? In the front area an abandoned servants' water closet—the pan broken, and the floor beneath the seat flooded with sewage. This was doubtless the source of the smell perceived at the hall door, and ascribed by the servants to the dust-bin of a large family that inhabited a house a few doors off. It has never been my fortune to encounter anything more abominably foul and loathsome, and it was only by liberal douching with carbolic acid that it was rendered approachable by the workmen. Nevertheless, into the drain leading from this filthy latrine ran the waste-pipe of the large cistern that supplied the kitchen and furnished drinking water to the household. Two water-closets of the old pattern in the interior of the house were also horridly foul, while into the traps beneath them ran the wastes from sinks and cisterns. In that house I caused every waste and water pipe to be disconnected, and to open either into a water head, or over a gully trap, and three old closets were replaced by patent valve closets. The whole was done at an expense of about £50.

IV. I now turn to the fourth and last of the cases I have selected, of which I have here two plans, illustrating, *in part*, the former arrangement of the drainage, and the alterations that have since been made. In this instance it was the cook, a young woman of delicate constitution, aged about 27, who fell ill of typhoid fever. She slept in a small room immediately adjoining this sink, with her head turned towards it, so that when the door was open or ajar she may very well have respired any foul air that escaped from it. But in the scullery there was also an unprotected sink in communication with the drain, which might equally well have communicated the contagion. Now let me relate to you as briefly as may be the history of the house to which I am referring. It is interesting in more than one point of view. The lease of the house for a very long term was bought by its present proprietor only three or four years ago, on the occasion of his marriage. Not only a leading builder, but an eminent architect, were employed to put the house into thorough order and repair, without any limitation as to expense. Mediæval furniture and decorations adorn the sitting-rooms and line the staircase, while, unfortunately, the architect's mediæval propensities extended also to the entire system of drainage. In the basement an old brick drain traversed the house from back to front, and actually entered the main sewer in the roadway, without the intervention of any kind of trap (see general plan). Into this brick drain ran all the wastes of the lower offices, the rain water pipes from several flats, and the soil pipes of two sets of water closets. But even amidst this general badness there was a distinguishing peculiarity, a certain refinement and concentration of evil. It is feebly portrayed in this plan, but I hope to make the description as forcible as it deserves. Underneath this staircase on the third floor stands a housemaid's sink. It had previously been a water closet, but the water closet, as you see, had been removed so as to adjoin the outer wall of the house, and the place was made to serve as a housemaid's sink. Attached, of course, to the former w.c., was a soil pipe, *and into that disused soil pipe the architect and builder conducted the wastes from the large cistern and sink upstairs and the housemaid's sink.*

In conclusion, I have to add only a few words of a practical kind, in view of the circumstance that we may at any moment be consulted, or have occasion to satisfy ourselves as to the fitness or healthfulness of particular drains. When a medical man is placed in such a position, the points to be ascertained are these :—

1. Does the safe of the water closet communicate with the D trap?
2. Are the water-closets old and foul?
3. Is the soil pipe properly ventilated and carried above the highest windows on the roof?
4. Are wastes and rain-water pipes disconnected so as to discharge in the open air?
5. Is the house-drain formed of glazed stoneware of 6″ or 4″ in diameter, and properly ventilated?
6. Is there a good syphon trap situated between the extremity of the drain and the main sewer in the roadway?

Only where those conditions have been rigorously fulfilled can a dwelling house be said to enjoy immunity from sewer gas, and from the evils that follow in its train.

Clinical Records.

CASES IN PRIVATE PRACTICE.

Case of Concealed Hæmorrhage.

By T. H. STOCKER PULLIN, M.D., M.R.C.S.,
Sidmouth, Devon.

THE following case may be of some interest to the readers of your valuable journal :—

I was engaged to attend a Mrs. S. in her approaching labour; I was summoned by her husband on the 10th of April, and in answer to the call I went, and after examining my patient, I found the os uteri dilated to the size of a 5s.-piece, the liq. amnii came away previously; the vertex presented, the pains were feeble, irregular, and inefficient. I administered liq. ergotæ, min. 40, she complained of feeling faint; she had no rest for three nights, her pulse was rather feeble, but nothing marked to attract attention. She looked anæmic, but her friends informed me that she always presented a paled appearance, I therefore put her condition down to insufficient rest, as I could assign to it no other adequate cause.

Everything went on well until the child was born, which unhappily was dead, when everything revealed itself. There was profuse hæmorrhage, with detached placenta; the patient became very restless, with extreme exhaustion, the pulse feeble, quick, and compressible; I at once cleared away all clots, and gave an injection of liq. ferri perch. (B.P.), 1 part to 8 of water, a quarter of an hour later, I gave another injection of hot water at 120 deg., in order that it might have the effect of stimulating the patient. I applied firm pressure to the uterus, and gave a full dose of tr. opii, together with stimulants, in half an hour the hæmorrhage had almost subsided,

occasionally a little oozing, in about an hour and a half the uterus was as firm as a cricket ball, and all hæmorrhage stopped. I remained with the patient until 5 o'clock, and left her in a comfortable doze, I called again later, and found her certainly out of danger.

The object of my contributing these few hasty lines, is to show how these cases of concealed hæmorrhage may prove very serious, and almost fatal, before the true nature of the case is recognised.

Transactions of Societies.

SURGICAL SOCIETY OF IRELAND.

THE last meeting of the Session was held on Friday evening, March 29th, 1878. The President, Dr. Robert M'Donnell, F.R.S., in the chair. Dr. B. Wills Richardson, Hon. Sec., read the minutes of the previous meeting, which were confirmed.

Dr. SWAN read

AN ANALYSIS OF 40 CASES OF CLUB-FOOT,

which will be found at page 341.

Dr. ELLIOTT said that one of the cases Dr. Swan had alluded to, a valgus, being of only five years' standing, appeared to have made very rapid advance. He wished to know if the ordinary starch bandage was sufficient to retain the limb *in situ*? He had not found the starch bandage so successful, and he thought it was partly a delusion to apply it where the weight of the body of a patient of the age this one was, was thrown upon the limb. Dr. Swan said he did not apply the starch, or rather the plaster bandage to that particular case, but he applied the boot which he had described. Having divided the patient's peronei and extensor digitorum tendons, and by manipulation, he got the arch reformed, and then applied the boot. Dr. Elliott said the reason he asked the question, was because so far back as his residency in the Richmond Hospital, 35 or 36 years ago, Dr. Adams took in several cases of this kind, and it was very difficult satisfactorily to turn those cases out; when he said satisfactorily to turn them out, he meant to turn them out to what they might call the public satisfaction, to make them satisfactory, good cases. They found that by using a stiff application of the kind just referred to, that although the foot might for a time be partially brought into position, yet at the same time it was not satisfactorily restored without a more forcible application to the sole of the foot, because the whole of the arch of the foot became obliterated as in the instance illustrated by this cast. There was no operation usually requisite, although he (Dr. Elliott) had divided the tendon in some cases to enable him to restore the arch of the foot. By suitable appliances they raised the arch, and then a proper boot was used, that would maintain the arch in position afterwards. Dr. Swan's was a very interesting case, because they saw so many of them, but at that age he (Dr. Elliott) had always found that it was necessary to have something very substantial under the sole of the foot to keep it up, more than a bandage.

Mr. TUFNELL was desirous of asking Dr. Swan as regarded the early cases what method he adopted for making the extension, because in ordinary cases of clubbed foot, the plan that he (Mr. Tufnell) had been in the habit of adopting for some years, was one that he found sufficient. The plan was this: to take two pieces of sticking or soap plaster, he might say at once that it was a modification of the American extension plan, one on either side of the leg from below the knee joint to the ankle, doubling or rather trebling the soap plaster at the bottom, and having counter spaces, one below the knee and the other above the ankle, to prevent it from slipping. Draw that down over a small fulcrum, by placing a piece of cork at the bottom of the foot, with a tin splint, and knotting the pieces of plaister below it, they had immense power. After the division of the tendons, and the foot was put into its natural position on the splint, the foot piece of which for cold weather he had covered with a small piece of cork as a non-conductor, and knetting the sticking or soap plaster which he had converted into a kind of sling, he found this splint did not slip at all, and the child was enabled to paddle along on the ground, and it was impossible to move the position of the foot which was strapped on to the tin splint by the plaster, the weight of the body being thrown above. That splint could be kept on for a fortnight. He had those splints made by Messrs. O'Neill and Thompson for about three-shillings, according to the size of the child. He had spent a considerable sum on different kinds of instruments, and he had found none so useful as the simple appliance which he had described. With those other instruments the child managed to wriggle its foot away, and in six or eight hours afterwards, they found the distortion almost as much as it was before the division of the tendons.

Dr. STOKES said that while listening to the very interesting paper which Dr. Swan had read to the Society, he was struck with the fact that the very simple appliance of Mr. Tufnell's was not alluded to in it. He (Dr. Stokes) might mention that during the last eight years he had used no other method, in the subsequent treatment of clubbed foot, and he had the notes of upwards of thirty cases of different varieties of clubbed foot that he had treated entirely by means of that appliance by Mr. Tufnell's, and in all but very few had he had very satisfactory results. He might also mention that his colleague, Mr. Thomson, had also very largely used that splint, and he believed he was right in saying that Mr. Thomson also entertained a very high opinion of it. It certainly was a very simple and efficacious appliance, and it was quite uncomplicated, as the members would understand from Mr. Tufnell's description of it. There was one thing connected with the use of plaster of Paris, that he (Dr. Stokes) would like to ask Dr. Swan a question about. It struck him (Dr. Stokes) that the plaster of Paris bandages in very young subjects was open to the great objection of being affected by the urinary incontinence that was so frequent in those who were operated upon for clubbed foot at that age. The way they had at the Richmond Hospital of keeping that splint in place, was by the use of the paraffine bandage, and the urine had no effect whatever in softening that, and it could be kept on for a very considerable time. He doubted very much if that could be the case in the use of gypsum, or plaster of Paris. There was one other point to which he would like to refer. Mr. Swan had spoken of a great number of cases that he had dealt with, in which he had divided the tibial tendons. His (Dr. Stokes') experience of these cases might not be so great as that of many persons who were present, but he must say that the cases that required more than the division of the tendo-Achillis or the plantar fascia, had been in his experience extremely exceptional, in fact in almost all the cases that he had dealt with he had found that division of one or other or both of those structures was sufficient. He might mention an observation of his late revered instructor, Mr. Adams, which was to the effect that any case that did not yield after the division of those structures, was not amenable to surgical operative interference at all. He (Dr. Stokes) did not endorse that declaration altogether; it was a little too sweeping, but of this he was certain, that in the vast majority of cases it was quite unnecessary to divide anything more than the tendo-Achilles, and it might be also some of the fibres of the plantar fascia. On that point it would be extremely interesting to have the opinion of Dr. Elliott, who had had, he supposed, about the largest experience of anyone present in the treatment of these deformities.

Dr. ELLIOTT said that in no case of distortion like this that he had ever had under his treatment either in hospital or in private practice, had he ever been able to overcome that deformity without the steady elevation of the foot by much more substantial means than that of a starch bandage. He had been using since the time when he was a very young man, a plan of treatment which was used for this particular distortion by his respected friend the late Professor Smith, and had used it very frequently in Richmond Hospital, and that was by screw power to raise the bones into their natural position, and when they were got into their natural position, and the foot perfectly restored to its shape, then they might apply some artificial means, such as a boot to enable the patient to walk about; but without that gradual elevation of the bones into their natural position, and the restoration of the natural arch of the foot, he never saw a case succeed, though in infants it might be different. Very few of those cases—he might select for instance, the cast of an infant's foot, exhibited by Dr. Swan—required more than one single operation, and the

plan he (Dr. Elliott) had adopted; he did not want, however, to lay it down as a rule for any person, but he used Dupuytren's splint for fracture of the fibula reversed on the outside of the leg, and after reducing the limb to a state of equinus, he divided the tendo-Achillis. There was then but one deformity to redress, and that was the equinus; except in patients of advanced age, they—he alluded to the late Mr. Adams, the late Mr. Cusack, and several others who had passed away—had never divided anything except what actually resisted the restoration of the foot.

Mr. B. M'Dowell—Did you touch the plantar fascia?

Dr. Elliott—Yes, particularly the inner edge of the plantar fascia. Dr. Elliott proceeded to say that the experience of Sir Philip Cramptom, and of those who had treated many of these cases, led them to say, "Don't cut anything unless it opposes you; if it opposes you then cut it, but not till then." He (Dr. Elliott) had invariably found in cases in children of just merely everted foot, that they could be satisfactorily treated by the simplest splint on the outside, and when the splint was so placed, then to divide the tendo-Achillis, and the foot would go into its natural position. He fully agreed with Dr. Stokes upon that point. He (the speaker) did not see what could be gained by cutting tendons that did not oppose them.

Dr. Barton said there was one point to which he would like to call attention for a moment. Dr. Swan had stated in his paper that it was a great matter in the treatment of such cases after the division of the tendons, to let, as far as possible, the child run about so as to move the muscles. He thought that was a very important point, and it suggested to him that in reference to that point, he did not think the method of treating by an elastic band, originally suggested by Barwell, had been mentioned by Dr. Swan. Perhaps he would tell the meeting in his reply, what he thought of it? He (Dr. Barton) had frequently used this method of an elastic band in the after-treatment, with, he thought very great benefit. It was a simple band, and it fulfilled that which, he thought, with Mr. Swan, was an important principle in the after-treatment, and that was, if possible, to allow the child to run about. He remembered the late Mr. Syme dwelling upon that when he was a student, and he thought it was an important and valuable method in the after-treatment if it was possible to follow it. That was the plan that he (Dr. Barton) had adopted; a small pot hook in the outer part of the boot, about three-quarters of the distance forward (the point could be selected in each case where it should be) and so make a sort of external muscle of the elastic band, which freely played in a ring attached to a strap above the knee. There was a simple method of uniting the two ends of the elastic which could thus be made as tense as the case required. By the aid of that in the after-treatment, the little child could run about, and thus aid in the development of the muscles, and thus by its weight assist the action of the treatment.

The President said he had heard with some satisfaction indeed, but some surprise, Dr. Elliott's experience with regard to the fact that he did not find it necessary to divide any tendons except the tendo-Achillis. He (the President) had had a good many of these cases, and of course they were met with in general hospital practice. It was an easy thing enough to get the foot straight with the leg, and to reduce such cases as this to a condition of equinus; but they were excessively likely to return again, and in many of those cases when they moved the foot straight they felt the anterior tibial as tight as a fiddle-string, but it became gradually recontracted, and in a short time the deformity returned again. In two cases he had had an opportunity of dissecting carefully a foot of the kind, and in those instances it was quite obvious that the anterior tibial and the posterior tibial, as well as the tendo-Achillis, were tendons upon which there was very great strain, upon which there must have been very great strain in any attempt to move the foot into its normal position. The experience of no surgeon of a general hospital could be of much value when it was set beside that of a person like Dr. Elliott, who had given so much of his attention to this subject, and it was, therefore, very encouraging to hear that many of those cases could be grappled with without the division of those tendons. Some years ago he (the President) used to visit London oftener than he had time to do now; he used to spend some of his time at the Orthopædic Hospital there, with his friend Mr. Holmes Coote. The practice there at that time invariably was to divide these tendons. The anterior and posterior tibials were, he thought, in a bad case of equino-varus invariably divided. He could hardly think that in an institution like that, where there was such a large number of cases, and where some of the surgeons were very much in favour of doing what could be done by stretching; and he recollected that at the same time he was astounded at the results he saw of stretching cicatrices, and the ingenious appliances to the limbs and to the head and neck, notwithstanding all was being done that could be done in the way of stretching, it was still found necessary to invariably divide those tendons. He would be glad to learn from Dr. Swan what his experience was of the accident, when it happened, of dividing the arteries? He (Dr. McDonnell) remembered particularly inquiring about that when he was in London, and he found that at the Orthopædic Hospital they made little of it. The child bled smartly for a moment or two, but the hæmorrhage in no instance that he had met with, or that the Orthoædic Hospital surgeons in London had seen, was alarming. He (Dr. McDonnell) thought this was a matter of great importance, because those surgeons who were not specialists in this subject were often timid about touching the posterior tibial artery. If, therefore, while seeking to avoid it, the surgeon met with the accident, knowing that it was not serious, he would be bolder in having recourse to division in those cases where on account of their gravity it appeared to be a necessity for their treatment.

Dr. Swan, in reply, said it was an omission on his part not to mention that he had very frequently used the ingenious splint which Mr. Tufnell described, and which was his own plan. He believed it was known as the L shaped splint, and he had used it often with very beneficial results. However, there was such a large number of very ingenious instruments that he had not had time to allude to them, and that was how it came about that he omitted Mr. Tufnell's appliance; it was not that he did not fully appreciate the value of the instrument. With reference to Mr. Stokes's observations as to the effect of the urine upon the plaster, he did not think that was of much importance, because the plaster being only left on a few days until its removal, could scarcely be softened by the urine if the mother of the child was directed to put a piece of flannel about the upper part of the plaster. Regarding Dr. Stokes's experience as to the division of the tibials not being necessary, but that the division of the tendo-Achilles was usually sufficient, he (Dr. Swan) could only state what he felt himself to be the case, that he did not think the division of the tendo-Achilles was in all cases of such importance as the division of the tibials; viz., when calcaneo varus was present; in fact, he did not think the division of the tendo-Achilles necessary unless there was equinus He thought in the majority of cases of equino-varus the division of the tibials was at least as essential as the division of the tendo-Achilles. That was his experience; he might be wrong, but that was what he thought. He thought it was very easy, as the President had stated, to bring the foot into a straight position or into a state of equinus, but the deformity was sure to return; and that, he thought, was the great objection to Barwell's method of treatment as a curative method He was not referring to the application of Barwell's method in the way that Dr. Barton had referred to it, which he thought was a very good method indeed as a remedial agent after division, but he thought stretching the tendon without division an inefficacious method of treating club foot. He had listened with great respect to the observations of (Dr. Elliott. He (Dr. Swan) thought they should regard anything that Dr. Elliott stated as worthy of careful attention, remembering his vast experience in these cases, but he (Dr. Swan) regretted that he could not honestly endorse what Dr. Elliott had stated. He thought the tibials should be divided in the great majority of cases of club-foot in order to obtain a perfect cure. He knew that many cases might be turned out which would do, but after some months when seen by other surgeons, or by the surgeon who treated the cases, they would give great dissatisfaction. Regarding the valgus to which Dr. Elliott alluded, he (Dr. Swan) did not in that case treat the affection with the plaster bandage, but having divided the peronei and extensor tendons, and allowing the new tissue to unite the tendons and by careful stretching, and by manipulation having got the arch pliable, the soft plate was applied under the astragalo-scaphoid joint with the boot which he described. He had

no doubt that the method to which Dr. Elliott had referred —that of the cog wheel—would answer some cases, but he (Dr. Swan) thought it would be a more complicated method of treating cases than that to which he had alluded. Mr. Barton's observations had been extremely pertinent. He (the speaker) thought it was extremely important to develop the muscular structures of the limb, especially the muscles which were stretched in the first instance by the existence of the deformity; and he thought they should at all times aim at the development of those muscles either by friction, manipulation, electricity, or exercise, if it was possible to maintain the foot at the same time in its proper position. He had repeatedly used Mr. Barwell's method as an adjunct to the treatment after the division of the tendons, but he thought it was not a treatment to be recommended as a curative treatment alone. During a recent visit he paid to London, he went through the various orthopædic institutions, and he found that treatment was not in favour with the surgeons of the orthopædic hospitals of London, who had such vast experience in these cases. It was considered a nice way of making money, because patients did not like their children to be cut, and there was a great deal to be done in that way; but such cases fell into the hands of other surgeons who divided the tendons eventually. He quite endorsed the statement of the President in regard to the division of the tibials; equino-varus being a compound distortion consisting of three distinct deformities, rotation, and adduction of the anterior segment of the foot, and elevation of the heel; as a rule, the affection must require a removal of the forces which produced those various distortions, and he thought the first plan to be attempted was to cure the rotary varus, the adduction and rotation, and for the cure of that distortion he thought that certainly the division of the anterior and posterior tibials was necessary. With regard to the question of the division of the artery, he had divided the posterior tibial at least three or four times, and after the division he had put on a graduated compress. He had seen the foot suddenly blanch, but after a short time the circulation again entered the foot and no bad result followed, although he had occasionally read of serious results occurring afterwards in such cases. He would be very loth to divide both tibials, and he did not think any surgeon could be so unfortunate as to meet with such an accident. As he had before said, he had never seen a bad result follow the division of the posterior tibial. As to the length of time the plaster splint could be left upon the foot, he thought that would very much depend upon the amount of stretching that the foot would get on being placed in the plaster splint. He thought that generally three or four days would be long enough to allow the plaster to remain on, so that the muscles might be allowed to yield to the tension thereby exercised.

The President then read his concluding address, and the Session was brought to a close.

The Medical Press and Circular

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, APRIL 24, 1878.

FEIGNING DISEASE.

Forensic medicine and toxicology is not a favourite subject of study among the generality of medical students, but we are often hearing of some extraordinary incident which reminds us of the great practical importance of that department of medicine, and of the necessity of both pupil and examiner giving a due share of their attention to it. Among the subjects treated of in our works on forensic medicine is that of "Feigning Disease," the difficulty of detecting which, and the liability of the ends of justice being defeated by its successful practice, are well illustrated by a remarkable case of imposture which occurred recently in Wiltshire, and an account of which is given in most of the daily papers.

A man, who was indicted for felony, and was lodged in Malmesbury lock-up for due transmission to Devizes, was found next morning on the floor, apparently unable to move. His story was that he had got up to look out of the window, that he had fallen backwards across his bed, and that he had injured his spine. For nine weeks Neale was in the infirmary. Roast fowl, omelettes, jellies, custards, and various other savoury and nutritious articles of diet were provided for him. His general health improved, but the symptoms of spinal paralysis remained unchanged. Brought into court and lying helplessly on a pallet, he pleaded guilty to the charge preferred against him. The audience were moved to tears; the barristers evinced signs of commiseration; the learned judge was visibly affected, and could hardly restrain his emotion. "The infliction you are suffering under," said his lordship, "surpasses any punishment I can give you," and he accordingly proceeded to sentence the offender to eighteen months' imprisonment, which he afterwards, out of mercy, reduced to twelve. Owing, however, to circumstances into which we need not enter, he was seen by the Deputy-Governor of Gloucester Gaol, in which he had, on a former occasion practised some of his malingering tricks. The Deputy-Governor declared his conviction that the man had nothing the matter with his spine, and was simply shamming. The officials of the Devizes Gaol, on the other hand, were convinced that the poor man was in a terrible state, and that his symptoms were perfectly genuine. To settle the question an electric battery was brought into play, but for some time without any result. "At last," says the *Daily Telegraph*, from which paper we have taken the foregoing account, "the leg began to twitch convulsively. The suspicion previously aroused was aggravated; the battery was turned on to a greater strength, and the unfortunate cripple, lying paralysed and helpless on his bed, jumped up with the agility of an acrobat, and presently walked straight across the prison yard to get his gaol clothes. The man was as sound and healthy as any of the prison warders. His suffering was all a sham, but his adroitness has saved him from penal servitude, and secured him the comparatively lenient sentence of twelve months' imprisonment."

We do not recollect seeing or reading of a serious disease being so successfully feigned as in this case. For nine weeks this man was in the infirmary of Malmesbury Gaol, and it is certainly an extraordinary circumstance that during that time nothing should have occurred, and nothing should have been noticed, to arouse the suspicion of his medical attendants. We say "arouse suspicion," for evidently the true nature of this case was not suspected, or otherwise the test of the electric battery would have been resorted to before his removal to Devizes. At all events, the case is a good illustration of the ease with which a medical man may be imposed upon, unless he is on his guard, and more than usually sharp at detecting imposture of this kind. Besides, the art that is exercised, and the self-command that is often displayed by the malingerer is truly remarkable. Foderé (quoted by Guy),

speaking of the time when the conscription was in full force in France, says that malingering "was brought to such perfection as to render it as difficult to detect a feigned disease as to cure a real one." The most extraordinary devices have been used to feign disease, and the most painful tests have been borne in order to prevent the deception being discovered. One man successfully simulates coma and lethargy, every stimulant that is thought of is resisted, and even the operation of trephining causes but a single groan. Another man simulates deafness so perfectly that when he is asleep in bed and a pistol is fired off by his ear, he lies unmoved; a third, in a feigned fit of epilepsy, allows pins and needles to be run into him, hot and cold water dashed upon him, and even the application of the actual cautery. Indeed, so difficult is it sometimes to detect the real nature of these cases, that it requires as much ingenuity on the part of the medical attendant to expose the imposture, as skill and self-command on the part of the culprit who practises it. But this is all the more reason why medical men, when practising among a certain class of patients, should give a little special attention to the subject of feigned diseases, and should, in certain cases, ever have before them the possibility of the patient being an impostor. Even in civil practice the practitioner may occasionally come across cases of this kind, in the diagnosis of which any error of judgment on his part may be attended with serious consequences, and discredit him in the estimation of those who are aware of his mistake.

Those who are most familiar with the general character and symptoms of real disease, and whose skill and acumen in the diagnosis of disease have been improved by extensive observation, are not likely to be imposed upon by the arts of the malingerer. The case, however, is different with young and inexperienced surgeons, so many of whom begin practice among that very class of people, such as soldiers and sailors, which furnishes the greatest number of malingerers. The existence of motives for deception, the general character and appearance of the individual, his previous history, a minute and careful examination of the symptoms, a comparison of the symptoms and progress of the case, with good descriptions of the real disease, setting some watch upon the patient when he thinks no one is near him, taking him by surprise, and the application of such tests as chloroform, the electric shock, &c.; these are the chief means to be relied on in the detection of feigned diseases.

The great importance of the subject in a social and legal point of view has very properly claimed for it a place in all our text-books of forensic medicine. It is only one of the many interesting topics treated of in works of that kind, a fact, which should, as we have already remarked, induce the student and young practitioner to make this department of medicine a special subject of study, and the examiner a special subject of examination. We believe that in the proposed Conjoint Board of the English Examining Bodies forensic medicine and toxicology is not made a separate subject of examination, but is to be taken in connection with chemistry, medicine, and midwifery. This is a plan to which grave objection may be taken. What is worth doing is worth doing well, and we can scarcely expect the student to give much attention to a subject which is virtually ignored by his examiners. It has always been made a special department of the examination at the Apothecaries' Hall, a fact which accounts for the general practitioner having more knowledge of the subject than could otherwise have been expected of him.

THE CRISIS OF MEDICAL REFORM.

Our journal of last week was, perhaps, more pregnant with the future interests of the profession than any which has reached the hands of our readers for the last twenty years. We reported the debate in the Medical Council upon Professor Humphry's motion, which declared emphatically that "no medical legislation relating to examination will be satisfactory which does not provide for the formation of an examining board in each of the three divisions of the kingdom," and we recorded the gratifying intelligence that, in the teeth of every opposition which the Scotch Colleges, the Queen's University, and—we blush to say it—the Irish colleges could offer, the resolution was carried by a majority of 14 to 10. In favour of reform—*i.e.*, for the resolution—were the President of the Council, the representatives of all the London colleges, of all the English universities, and of the Irish Apothecaries' Hall, and, with the exception of the Scotch nominee, of all the Crown representatives in the Council. For resisting reform, *i.e.*, the *status quo*, were the Scotch Crown representative, to whom we have referred, and the representatives of every Scotch and Irish college and university, the honourable exception being Dr. Leet, as above noted. This resolution, coming from a body notoriously averse to reform, and essentially representative of the personal interest of licensing bodies, as distinguished from the general interests of the public and the profession, cannot fail to influence powerfully the Duke of Richmond to amend his bill, and to stimulate the profession to make its voice heard on the subject. If his Grace can read the division aright it will teach him another lesson worthy of his consideration. It will show him that nearly one-half the Council is ready to exercise its most powerful influence in diametric antagonism to the feeling of the profession, and that the Medical Council is, therefore, only in a limited sense, representative of the opinions of the medical profession, for we assert emphatically, and without fear of contradiction, that, if it were possible to poll the entire medical profession, outside the circle of those who have personal interest in teaching, at least three out of every four votes would be for reform of the present system, and for compulsory conjoint examination as the mildest measure of reform. A majority of the Medical Council has certainly spoken out the opinion of the medical profession, but the verdict thus delivered derives far greater importance from the number and nature of the minority than from the fact that a narrow majority decided in favour of medical reform. Of that majority it may truly be said that they express the opinions only of the most timid, most conservative, and least decided section of the profession—of those respectable elderly gentlemen who, experiencing no discomfort from the competition of half-licensed practitioners, who have been for half-a-century educated to a tolerance of

diploma-vending, who think that abuses of all sorts are best left to settle themselves—and even this section of the profession feels conscientiously that the abuses of medical education and licensing have risen beyond the toleration point, and the majority of the Medical Council has accordingly decided in favour of reform. But what has it been left open to be said of the minority? That they are the representatives of nothing but pocket interests of colleges to whom the earning of fees and the selling of diplomas is dearer than either principle or future prospects; of lecturers and teachers to whom medico-educational improvement signifies only the loss of so many pounds, shillings, and pence. That the General Medical Council contains ten such members—gentlemen who are content to vote and speak in direct variance with the feeling of the profession, ought surely to convince the Duke of Richmond that a *pronunciamento* in favour of medical reform by the General Medical Council needs to be multiplied tenfold in strength and emphasis before it can be taken as representing the anxiety of medical men for some measure which will rescue medicine from the control of the licensing corporations.

We are glad to learn that the Medical Reform Committee of the British Medical Association is taking energetic steps to bring the wants of the profession, in these respects, more clearly before Parliament, and we hope that the medical men of Ireland will not fail to make it understood that the votes of the Irish representatives of colleges against medical reform do not represent the feeling of the profession in Ireland.

SANITARY INSPECTION IN IRELAND—OUTBREAK OF MEASLES IN THE COUNTY LIMERICK.

At a recent meeting of the Limerick Sanitary Board the L.G.B. Inspector read a letter from Dr. Keyes, of Cappamore, stating that he had attended 150 dispensary patients suffering from measles in Cappamore town and neighbourhood, while private patients attended by him amounted to 60. The total number of deaths since the outbreak amounted to 24. The disease was of a most malignant type, amongst the poor especially, the lungs and kidneys of the patients appearing to suffer most severely. Infection was the cause of the outbreak, the disease having been brought to Cappamore from the neighbourhood of Tipperary. The disease has been much influenced by the ill-ventilated homes, the extreme poverty of the poor, the bad sewerage of the village, and want of cleanliness of the people. The Clerk read a letter from the Local Government Board urging that the state of Cappamore could be ignored no longer, and asking the Sanitary Board to discuss the matter without loss of time.

Thus is exemplified the policy of the Irish Local Government Board and its natural result. The sanitary condition of this district has for many years been admittedly as bad as it can be, and it is not until now, when twenty-four lives have been sacrificed to an epidemic, that the Irish Local Government Board takes any step towards a reform. Probably, it was profoundly ignorant as to whether the district was wholesome or the contrary, whether the sanitary authority was stirring or indolent or obstructive, and whether the medical officer of health was doing his duty or not. Under the present ridiculous state of public health system the Local Government Board must remain in primitive ignorance upon these points, because it is absolutely without any means of sanitary supervision or inspection. It has, indeed, full powers under the Act to appoint inspectors of sanitation, but for two reasons it does not exercise those powers. *Firstly*, it has no desire to hasten sanitary reform in Ireland. Strange as it may appear, the Irish Local Government Board has always been on the side of *laissez-faire*, and has, during many years in which the Public Health Acts have been in operation, done little or nothing to stimulate improvements, but, on the contrary, has discouraged every effort to stir up sanitary authorities to action. At the present moment it would seem to know almost nothing and to care less whether any individual sanitary boards or its officers are doing their duty, and, as a matter of fact, at least, one-half of the authorities *have* done nothing and are not disposed to do anything, and their officers dare not initiate active intervention against the will of their masters. But, *secondly*, if the Irish Local Government Board were ever so zealous for sanitary supervision as a means to improvement it is hardly in a position to appoint the needed inspectors because it has no means of paying them. The usual course—that pursued in England and also in reference to the Irish Poor-law inspectors—would be to have them paid from the Consolidated Fund, the work done being a strictly Imperial service. But the Lords of the Treasury oppose to the granting of money for such purposes *in Ireland* a rigid opposition. In this, as in other instances in which subsidies are required in Ireland equivalent to those granted for similar objects in England, their Lordships calmly draw their pen through the money clauses and, practically say, "You may appoint any one you please for any purpose you please, but don't ask the Treasury for money. Put the cost on the poor-rates, or the grand jury, or any local fund you please, but if you can't have officers without drawing on the Consolidated Fund you may do without them." On the appointment of the dispensary doctors as sanitary medical officers in Ireland they adopted this course, and only assented to their being paid at all on the expressed understanding that they should receive nothing more than a nominal salary. For sanitary inspection, for vaccination, and other analogous services, sums are paid by the Treasury annually to England much larger in proportion than the sums asked for Ireland, and yet the service cannot be carried out in Ireland for want of officers for whom the necessary salaries are refused.

Notes on Current Topics.

Sensational Therapeutics.—II.

Among the more ephemeral productions that appear every week in the columns of our medical periodicals (our own, of course, included), are certain therapeutical communications which must have a great charm for those whose credulity is stronger than their judgment, whose mode of reasoning is on the *post hoc propter hoc*

principle, and in whom a little rational scepticism seldom directs the due interpretation of the facts that are brought under their observation. It is a sad reflection, but nevertheless true, that Credulity and Superstition are to be found even among the more legitimate walks of science, especially in that attractive domain devoted to the cultivation of therapeutics. Driven from other quarters, they still find here convenient pasturage on which to fatten and prosper. We shall therefore make no apology for occasionally returning to the subject of "Sensational Therapeutics," in the hopes that, with the assistance of those who are equally anxious to keep this department of medicine free from error and superstition, we may in time succeed in mitigating the evil results of the influences above referred to. Our illustrations will not be taken from any particular journal, but from any and all of them, just as they happen to meet the eye. Very recently we noted an extraordinary communication in one of the most respectable of English periodicals with reference to the wonderful therapeutic efficacy of injecting a few drops of cold water under the skin. This week it is a communication in an American publication which excites our keen sensitiveness to whatever partakes of the marvellous or ridiculous.

The public are too well acquainted with the dangerous character and fatality of diphtheria not to be thankful to anyone who will discover a certain cure for it. Perhaps a correspondent of the *Philadelphia Medical Times* may claim such a discovery. Being convinced that diphtheria is not due to a poison of the blood, but to an excess of fibrine corresponding to the inflammatory diathesis, he has been treating all his cases with heroic doses of calomel, and declares that by this treatment he has had a high percentage of cures. His treatment is calomel in large doses every hour until the stools "resemble the fresh water-polyps in water-troughs, gelatinous, and of a bright green hue; then the patient is safe"! The proof of correct diagnosis is, "should prostration follow such heavy doses," the case is not diphtheria, but tonsillitis! This gentleman has given some of his young patients as much as *half an ounce* of calomel in four days' time. In another journal we read of a medical man administering very large doses of acetate of lead in post-partum and other hæmorrhages. The drug was given in half-drachm to drachm doses, and notwithstanding the prevailing opinion to the contrary, a number of cases are cited to show that these large doses of acetate of lead are perfectly harmless. Again, more than one eminent physician has said that we cannot "cure" fevers, and most members of the profession admit the truth of this dictum; but in the *Boston Medical and Surgical Journal* we are informed that a doctor "has cured thirty-nine out of forty cases of typhoid fever by a nitrate of silver treatment," in which, however, other remedies were employed, thus at once vitiating the confident conclusion arrived at by our too sanguine and illogical *confrère*.

The Weights and Measures Bill.

This Bill has undergone the ordeal of consideration by a Select Committee of the House, from which it has come in a somewhat modified form. The alterations are not very extensive, but one of them will require the serious attention of chemists and druggists. The *Pharmaceutical Journal* says—"On a former occasion it was stated that clause 20 of the Bill, apparently in deference to the wish of the Council of the Pharmaceutical Society, made it permissive to use the 'apothecaries' weight' when selling drugs by retail; but it was also pointed out that no provision was made for a scruple or a drachm standard, although to be in possession of a weight not of the denomination of some Board of Trade standard was to render a person liable to a fine of five pounds. The Select Committee has removed the inconsistency by removing the permission to use apothecaries' weight, and in doing so has so far decided that henceforth to sell a drug by the apothecaries' drachm or scruple shall be deemed an offence."

The Bill is now set down for consideration in Committee of the whole House on the 9th of May. "It may be remarked (says that *Journal*) that should the Bill pass in its present form not only will it be illegal to use or even to be in possession of an apothecaries' drachm or scruple weight, but it will be an offence to print any return, price list, or price current in which such weights are quoted, the offence being punishable by a fine not exceeding ten shillings for every copy of such price list or price current published."

Drunkenness and Dipsomania.

In an able article in the current No. of the *Journal of Psychological Medicine*, a journal to which we have been often indebted for an interesting "Note," our attention is drawn to a valuable table, containing the family history of 23 dipsomaniacs. As the table is a striking illustration of the hereditary tendency of the dipsomaniac to his peculiar malady, we shall quote it *in extenso*. Thus Nos. I. and II. (brothers.) Father a dipsomaniac, grandfather very excitable, eccentric, and a drunkard. III. IV. and V. (two brothers and sister,) A brother insane, maternal aunt a dipsomaniac, parents temperate. VI. and VII. (brother and sister.) Father an habitual drunkard, paternal uncle a dipsomaniac, sister a dipsomaniac and a thief, two cousins-german dipsomaniacs. VIII. Father an habitual drunkard, brother an idiot, cousin-german insane. IX. and X. (brothers.) Mother a dipsomaniac, maternal aunt a dipsomaniac, maternal uncle an habitual drunkard. XI. Father insane. XII. Brother a dipsomaniac, mother insane. XIII. Sister committed suicide. XIV. Father, a brother and sister, and several cousins, drunkards or dipsomaniacs. XV. and XVI. Paternal aunt insane, maternal grandmother insane, mother a dipsomaniac. XVII. Mother of Nos. XV. and XVI. XVIII. Brother a general paralytic, sister weak-minded. XIX. Father insane, and committed suicide in an asylum. XX. Uncle and cousins dipsomaniacs. XXI. Father and mother temperate, family strumous. XXII. and XXIII. Parents temperate, and family history good. Thus it will be seen that in no less than 20 out of these 23 cases, the parents, or other relatives of the dipsomaniac, had been either dipsomaniacs themselves, or had suffered from some form of insanity. And does not this table also show that our opinion of the character of the dipsomaniac should, in most cases lean to mercy's side; and that he is often more to be pitied than to be blamed? On the other hand the habitual drunkard might see in these records the deplorable consequences of

his vicious indulgences—sins that are visited upon his children unto the third and fourth generation. Apropos of the term "habitual drunkard," a distinction should be made between that term and the term "dipsomaniac." Dr. Cameron, Medical Superintendent of one of the Scottish asylums, to whom we are indebted far the above table, quotes a passage from Bucknill and Tuke's "Psychological Medicine," in which this distinction is well observed. The typical dipsomaniac drinks under the influence of an uncontrollable desire for alcoholic stimulants and in solitude, and is in every instance quite unfit to carry on any occupation continuously. The ordinary drunkard drinks for pleasure, in the company of boon companions, and at irregular intervals, as opportunity presents itself. The dipsomaniac drinks in obedience to an impulse which he cannot control, even though the wish to refrain may exist.

The Small-pox in Dublin.

According to the Registrar-General's return for the week ending April 13th, the deaths in Dublin are 30 in advance of the average of those of the 10 years' corresponding weeks. The death-rate is 32·2 per 1,000 of population, London being 27·6, Glasgow 25·0, and Edinburgh 29·9. The number of deaths from zymotic diseases registered during the week is 40, being 4 more than in the preceding week, and 15 over the average number in the 15th week of the last ten years. The deaths from these diseases comprise 15 from small-pox, 14 from whooping cough, 6 from fever, 4 from scarlet fever, 2 from croup, 1 each from measles, dysentery, &c. The deaths from small-pox are 5 in excess of the number in the preceding week; 3 are chargeable to the North City districts, 11 to the South City (of which 6 are chargeable to Peter Street—district), and 1 to Donnybrook. In five Dublin Hospitals, which admit persons suffering from this disease, there were 157 cases under treatment on Saturday, 13th inst., being three under the number in those institutions on the previous Saturday. The Registrar-General regrets that he has not been favoured with any information for last week on this subject as regards the Mater Misericordiæ Hospital. At Belfast four deaths from small-pox, 8 from fever, 2 from scarlatina, 3 from diarrhœa, and 1 from measles, were registered at Belfast during the week. The deaths from diarrhœa, and 1 each from measles and whooping-cough were registered at Cork. Two deaths from scarlatina, and 1 each from fever and diarrhœa were registered at Limerick. Four deaths from whooping-cough and 1 from measles were registered at Waterford.

Self-supporting Hospitals.

In connection with the financial difficulties of the London Hospital, the last number of the *Graphic* makes some very sensible remarks on the subject of self-supporting hospitals. "The question (it says) may be asked why the million of poor people who live round this noble institution cannot support it for themselves, without charitable aid from without. As matters now stand, the facts may be broadly stated thus. The people who use hospitals do not pay for them, the people who pay for hospitals do not use them. At first sight, no form of charity appears so free from objection as the support of hospitals by those who are well to do. They can thus give effectual help to a poor man just at the time when, from sickness or accident, he needs costly help, and when, because of the sickness or accident, he is unable to earn wages. Among the better paid and more thrifty members of the working classes, numbers do pay in some form or another for medical relief. Some employ regularly-qualified practitioners, others purchase advice and medicine from a druggist, others belong to clubs with salaried medical officers. And when persons of this class enter the hospital—at all events as in-patients—it is often not until they have spent much money in seeking relief elsewhere. We fully admit that beyond these there is a multitude of very poor or thriftless people who either cannot or will not pay for medical services so long as they can obtain them gratis. But we believe that the mass of the working classes would willingly contribute towards the support of our hospitals, provided an appeal was made to them in a more systematic manner than at present."

We would willingly endorse every word of these observations. When we reflect upon the extraordinary waste, extravagance, and intemperance that prevail among the working classes—among people who are every week in the receipt of good wages—it seems hard that the entire support of our great metropolitan hospitals should fall upon those who never use them. But, as the *Graphic* remarks, a systematic appeal to the charity and providence of the working classes has never been made. We believe, with that paper, that such an appeal would be partly successful, and that those who responded to it would, in the hour of sickness, feel some satisfaction that they contributed their mite towards the support of the hospital under whose roof they were sheltered and cared for.

Medical Sanitarians and Architects.

The *Irish Builder* has, it appears, a grievance against Irish medical officers of health in general, and those of Dublin in particular; and a special marked copy of our contemporary having been forwarded to us, we are, we presume, expected to reply or submit to judgment against us by default. We plead incapacity to answer, because having read the statement of the case by the *Builder*, we fail completely to comprehend its meaning. The *Builder* does our profession the distinguished honour of acknowledging that medical officers of health, when they are men of long experience, are a very useful class of public officials, but thinks "it will never be tolerated that medical men are to become directors-in-chief in all sanitary matters, including building construction, and that architects and engineers are to act as their clerks of works."

The *Builder* also requires to know "how many doctors know the constituents of good mortar, and what are the properties of sand and lime comprising it." From these quotations we derive the conception that our contemporary is jealous of the doctors. We hasten to reassure it. Irish medical officers of health have not the remotest ambition to undertake a larger field of duty than they have—being almost unpaid for that—and they gladly leave to the composition of bricks, mortar, and plaster—except sticking-plaster—to architects and engineers. In

the absence of any circumstance which justifies the *Builder's* complaint, it seems to us an unmeaning grumble.

Treatment of Œsophagism by Injections of Morphia.

THE *Practitioner* quotes from the *Gazette Médicale de Strasburg*, a case in which Dr. Richard was called to a patient suffering from suffocation and painful spasms of the œsophagus. The liquids introduced were violently rejected, and he could not even swallow his saliva. The symptoms came on suddenly; and no information was obtained from an examination of the throat, nor from the history. A free local bleeding, and several hypodermic injections of morphia effected a rapid cure, and on the following morning the patient, though much fatigued, could swallow well. These cases, observed M. Sieffermann, sometimes arose from the presence of foreign bodies in the œsophagus.

The Galway Anatomical School

Has received, within the last month, a very severe blow in consequence of a misadventure for which it can only be held semi-responsible. A coffin, supposed to contain the body of a person who had recently died in the workhouse, had been carried to the grave followed by relatives and friends. It is the habit in Ireland for every friend of the deceased to help to bear the coffin, and if the followers be numerous the funeral progress consists in a continuous shifting of the bier from one set of bearers to the other. It thus became evident to all concerned during the progress of the funeral that the coffin was unexpectedly light, and, on reaching the grave, suspicion being excited, it was opened and found to contain nothing but a few viscera. With loud outcry the daughter of the deceased gathered up the remains in her apron, ran shrieking to the workhouse door, and cast them down with imprecations upon the guardians and all concerned in the management of the house. It may be conceived that the excitement was great. The priest who was engaged to perform the funeral rights reported the matter to his bishop, who at once excommunicated the workhouse by ordering that no Roman Catholic clergyman should enter its doors for any purpose whatever until an *honourable amende* had been made.

Inquiry was made, and it was ascertained that in mistake for another body which was unclaimed, the deceased's body had been removed to the College School and there dissected, and that the remains had been given to the relatives.

A letter was addressed to the Guardians by one of the medical staff of the College, in which the following explanation was offered:—

"Bodies dying in the workhouse, and liable under Sec. VII of the Anatomy Act (*a*) to be claimed for dissection, are removed to the anatomical rooms of the college, and injected with preservative fluid. After dissection the remains are taken back to the workhouse and deposited in a coffin in accordance with the section of the Anatomy Act directing that the remains shall be 'decently interred in consecrated ground.' It has been the practice, so long as I have been connected with the school, that a dissected body should be deposited in the deadhouse in the room of each unclaimed body removed. In this way the burial of all dissected bodies is provided for. On Wednesday last the master of the workhouse, acting under an instruction of the Local Government Board which directed him to carry out the provisions of the Anatomy Act, notified to me that a body, liable to be claimed for dissection, was lying in the workhouse hospital. Instructions were given to the anatomical porter to remove this body to the college on Wednesday night. This was done on Thursday evening about five o'clock p.m. I was informed by the porter that the master of the workhouse had called to the college and stated that the body which had been removed was not the one referred to in his notification to me. Whether the mistake in the identity is to be attributed to the anatomical porter or to the workhouse official I do not know. I directed the porter to return the body immediately. This was done the same evening."

A meeting of the Board of Guardians being held, it was resolved, after much debate, that the supply of subjects to the School should be henceforth forbidden. Inasmuch, as the School has had much difficulty, heretofore, it will be placed in a great dilemma by this decision, and we regret that it should be thus inconvenienced in consequence of a mishap over which it had no control. It is needless to say that the College has had to contend through its whole life with violent religious antagonism, and that this opportunity has been gladly seized by an influential party to deal the institution a death-blow, all the virtuous indignation expended upon the subject by the local newspapers and the Board of Guardians being so much padding to cover the foregone conclusion to destroy the School by any or every means. We shall be gratified if the professors can find a way to parry the stroke and to bring the School to a state of increased efficiency.

The Army Medical Service.

AT a meeting of the Professors of the School of Physic, in Ireland, held in Trinity College, last week, it was resolved, in drawing up a reply to the letter of Her Majesty's Secretary for War, dated March 21st, to mention as the principal reasons which prevent the students of the Trinity College from competing in larger numbers for the army medical service.—1. The feeling of distrust produced by the frequent changes in warrants and regulations has caused a reluctance on the part of the medical students of the Trinity College to enter a service in which they are unable to calculate with certainty on their future career and treatment. 2. The recent short-service system, by which a medical officer is liable to compulsory retirement at the end of ten years' service. 3. The disadvantage at which medical officers are placed as compared with other officials in respect to several matters, such as sick and ordinary leave, and exchange and barrack privileges. In addition to the foregoing reasons, the medical students of Trinity College are of opinion that the adoption of the regimental system has seriously diminished the social and other attractions of the service.

(*a*) 7. And be it enacted, that it shall be lawful for any executor or other party having lawful possession of the body of any deceased person, and not being an undertaker or other party intrusted with the body for the purpose only of interment, to permit the body of such deceased person to undergo anatomical examination, unless, to the knowledge of such executor or other party, such person shall have expressed his desire, either in writing at any time during his life, or verbally, in the presence of two or more witnesses, during the illness whereof he died, that his body after death might not undergo such examination, or unless the surviving husband or wife, or any known relative of the deceased person, shall require the body to be interred without such examination.

Homœopathic Hedging.

At a meeting of the Homœopathic Medicine Society of the State of New York the other day, a resolution was adopted, declaring "that although firmly believing the principle *similia similibus curantur* to constitute the best general guide in the selection of remedies, and fully intending to carry out the principle to the best of our ability, this belief does not debar us from recognising and making use of the result of any experience; and we shall exercise and defend the inviolable right of every educated physician to make practical use of any established principle in medical science, or of any therapeutical facts founded on experiments, and verified by experience, so far as in his individual judgment they shall tend to promote the welfare of those under his professional care."

Measle Epidemic in Wexford.

At the last meeting of the Wexford Guardians, the clerk read a letter which he had received from the Local Government Board, calling the attention of the Board of Guardians to the fact of there being over seventy children affected with measles transferred to the Fever Hospital, and the Board pointed out that it would be desirable that the medical officer speedily report as to this epidemic, and the sufficiency of the accommodation available for the treatment of so large a number of cases. Dr. Crean, the medical officer of health, reported that the children affected with the epidemic, which was of a mild type, had been transferred to the shed of the Fever Hospital. The greatest number of them are convalescent. He had appointed four nurses, temporarily, which he considered sufficient for the emergency.

Sickness in the Russian Army.

That disease is often more fatal to an army than actual warfare is again strikingly illustrated by the latest accounts from the East. It appears that the Russians are dying at Erzeroum in large numbers. Drs. Ryan and Stokes assert that 21,000 Russians have succumbed to typhus fever during the last three months in the city and plain of Erzeroum. There is also much sickness amongst the Russians at San Stefano, owing to defective camp arrangements and the dirty habits of the troops.

Fever Cabs.

At the last meeting of the Public Health Committee of the Dublin Corporation, a letter from the commissioner of police was read, stating, that in compliance with the report of the committee directions had been given by him to watch cabs setting down parties in the neighbourhood of the fever hospitals in order to prevent the use of public cabs by patients suffering from infectious diseases.

Besides small-pox, London is visited at the present time by an epidemic of whooping-cough, the deaths from this cause having risen to 157 and 158 during the last two weeks, being considerably higher than in any corresponding period on record. The deaths, also, referred to diseases of the respiratory organs, which in the four previous weeks had increased from 340 to 474, further rose last week to 497, and exceeded the corrected weekly average by 143; 295 resulted from bronchitis, and 137 from pneumonia. London's proverbially healthy state appears to have forsaken her for the time being.

St. Petersburgh has again the highest death-roll of any city in the world which furnishes returns to the Registrar-General. According to the most recent weekly returns, the death-rate in that city was 62 per 1,000; Calcutta 42, Bombay 45, Madras 59; Paris 29; Geneva 25; Brussels 35; Amsterdam 32, Rotterdam 33, The Hague 29; Copenhagen 21; Stockholm 25; Christiania 18; Berlin 27, Hamburg 26, Dresden 29, Breslau 32, Munich 32; Vienna 33, Buda-Pesth 49; Rome 38, Naples 32, Turin 51, Venice 41; Alexandria 41; New York 23.

The rates of mortality in the four principal cities of the United Kingdom last week were:—Glasgow, 25, London, 28, Edinburgh, 30, and Dublin, 33, per 1,000 of the population. The death-rate was also high in Liverpool with 29 per 1,000, Brighton, 30, Manchester, 31, and Plymouth, 40, the highest rate in the kingdom, which is principally attributable to measles and whooping-cough.

The deaths from small-pox in London still further increased last week to 58. Of these 25 were certified as unvaccinated, 10 vaccinated, the remainder being uncertified. The number of patients in the metropolitan small-pox hospitals at the end of last week had risen to 785.

A case of quadruplets occurred a few days ago in the practice of Mr. C. Hadley, M.R.C.S., of Birmingham. All were born alive, two boys and two girls; two died the second day, the others the day after. The mother progressed favourably with no untoward circumstances.

Correspondence.

UNION HOSPITALS AND COUNTY INFIRMARIES.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—I read in your issue of April 10th, a report of Dr. Thompson, of the Tyrone County Infirmary, which demands prompt notice from some workhouse surgeon. Dr. Thompson, who, according to his own naïve admission, feels it necessary to administer "a much needed warning" to, we presume, the flagging supporters of his infirmary, modestly informs his hearers and your readers, that the sick labour under disadvantages in the workhouse hospitals, as compared with his model institutions, in the scientific treatment of medical and especially of surgical diseases. This means in plain English, and it can mean nothing else, that the medical skill at their disposal in union hospitals is inadequate to their proper treatment, and inferior to that which county infirmaries offer to them. As Dr. Thompson does not condescend to favour the public with the grounds on which he has based this remarkable conclusion, I now call on him to do so.

I shall say more hereafter, but for the present I shall content myself with challenging him to furnish his proofs of workhouse inferiority.

Yours &c.,

Thomas Laffan, Surg. Union Hosp., Cashel.

April 11th, 1878.

[We do not understand Dr. Thompson to put forth any

such view as that attributed to him. He argues—and, we think, justly—that it is necessary to maintain an infirmary in each county in order to accomodate the large and deserving class who will not—and ought not to be expected to—enter the workhouse, and we agree with him in the opinion that the county infirmary must necessarily possess advantages for the performance of capital surgical operations greater than those offered by any hospital in which the general run of workhouse sick have to be admitted. The superiority is not, however, a question of surgical skill, but rather of the suitability of the institution.—ED. M. P. &. C.]

Literature.

GUNSHOT INJURIES. (a)

IN the progress of civilisation, no more striking advance has been made than in the scientific methods of slaughter brought by contending nations one against the other. While, however, on the one hand, greater powers of destruction have been elaborated, medical science has not been backward in counteracting the havoc wrought in time of war by gunshot injuries and by disease. There is not one of the wars of recent years which has not been marked by greater skill, knowledge, and research in the treatment of sick and wounded soldiers; and, notwithstanding the increased numbers of men now brought into the field, the care of those disabled has not been thereby pushed aside. The literature, too, of different countries, of France, Germany, and America, has been enriched by works well known in the profession, in which surgeons have written the results of their experience in the field, practical treatises of wide value to the civil no less than to the military surgeon. So there is now added another by Surgeon-General Longmore, who in a volume of six hundred and eighty-six pages brings forward the experience which he has gained during a service of many years, both in times of war and in times of peace. "Gunshot Injuries, their History, Characteristic Features, Complications, and General Treatment," must be consulted by all army surgeons who would be conversant with the work they have to do. "The army surgeon" writes Professor Longmore, "must comprehend in its range the whole sphere of professional science and practice. He must, in addition, possess a variety of other knowledge, peculiar to army practice, in order to be a thoroughly efficient officer. He ought to be acquainted with the science and application of hygiene as regards bodies of men in all climates; the preparation of various technical returns and reports, and the nature and uses of all the articles comprised under the general term of field medical, surgical, and transport equipment." And to judge from the work before us, the distinguished author himself does not fall short of the standard which he raises for the army surgeon.

Turning to the book itself, we find it arranged in sections dealing in great fulness with the various branches of the subject; for example, "the means by which gunshot injuries are produced," giving in five chapters a complete history of the missiles and weapons now in use; "the causes which influence the nature, character, progress, and ultimate issues of gunshot injuries;" "the characteristic features and distinguishing signs of gunshot injuries;" their "symptoms and complications;" "administration arrangements for the care and treatment of wounded soldiers in time of war;" "statistics of gunshot injuries in warfare." And each one of the eleven sections is further divided into chapters, and the chapters into paragraphs with separate headings easy of reference, the copious notes being placed conveniently at the end of the volume rather than, as usual, at the foot of the page. And herein lies the chief fault of the book. It is far too long, too much spun out, there is too much in it with which the ordinary practitioner is perfectly familiar, and which has no especial connection with gunshot surgery. It is not to a special work on gunshot injuries that the student or hospital surgeon, whether at home or in the field, will turn for instruction on pyæmia, erysipelas, and tetanus, unless, indeed, such diseases and complications of injury are in their clinical, pathological, and practical aspects made clearer to him by the lessons of gunshot surgery. We cannot but think that the chapters on tetanus, for example, would have been improved by a greater condensing of the general symptoms and course of the disease, and by giving more prominence to the facts which war surgery can specially contribute to its elucidation. It is only on such practical grounds that the experience of war surgery can have any right to speak with special force, and by showing how this or that disease may be modified or called into being by conditions met with only in the field, or in the unusual surroundings of military hospitals. The impression may be altogether erroneous, but it is a strong one which the book conveys, that much which our author writes has been evolved from the recesses of his inner consciousness, rather than from the mind, which is the chiefest wealth of practical experience. We deprecate the custom of taking a solitary quotation, and placing it forward as an example of an author's matter or style; but we must give one out of very many of like kind as an instance of what we mean. In the paragraph on "disabling consequences of *gunshot* injuries of the head" (the italics are our own) we read: "The manner in which the cerebral disturbance is manifested varies very greatly in different cases. Headache is one of the most common symptoms, and this is sometimes intermittent, sometimes continuous. It varies in different cases, from pains of the most intense character to merely slight uneasiness. The injury to the brain may also exhibit its effects in weakness, or loss of function of one or more of the organs of hearing, sight, smell, and speech; or in simply diminished muscular power and sensory acuteness; or in more or less complete paralysis of the face, upper extremity, or of both upper and lower extremities, generally limited to one side." Gunshot wounds produce the very lesions which are likely to throw light on obscure points of neural physiology and pathology, and one well-reported case of nerve or brain lesion would have been of greater value than such a general statement as this, which any thoughtful practitioner might have planned in the quiet of his chamber, ignorant of the horrors of war, and having never heard the din of battle. A treatise dealing with "individual injuries incidental to special regions of the body and their particular treatment," matters "not discussed in the present volume," would surely be of more practical service not only at home but also in the field. Professor Longmore has the "necessary materials for the purpose, and he hopes at some future time he may be able to supply this deficiency in a separate treatise." While admitting and freely acknowledging the great value of much which the present work contains, we cannot refrain, after a careful perusal of the whole book, from expressing our disappointment with it.

We rejoice with the author that by the new Warrant medical officers will in future have the power of controlling all that concerns their special functions; and we do not doubt that with a removal of restrictions which have hitherto harassed and oppressed them, army surgeons will be better able to work for the good of their country and of their fellow-men, and for the advancement of the noble science to which they devote their lives.

(a) "Gunshot Injuries: their History, Features, and Treatment." By Surgeon-General T. Longmore, C.B., F.R.C.S., Professor of Military Surgery in the Army Medical School. London: Longmans, Green, and Co, 1877.

The Briton Medical Assurance.—The Annual Report of this established Life Office was presented to the shareholders and policyholders last week, and as it is mainly supported

by members of the medical profession, its progress has especial interest for them. It is a plain unvarnished statement in few words, which in the present time of bolstered accounts in life assurance is highly commendable. The business done is not of an extensive nature, but as risky lives are studiously refused, this is a better standard of assurance than large returns with the probability of ultimate collapse. The Report will be fonnd in another column, and speaks for itself.

Death from Lockjaw.—A death from lockjaw occurred in St. Thomas's Hospital on Saturday last. The deceased, a painter, was brought to the hospital a few days since suffering from injury to the lower part of the spine. Paralysis and lockjaw set in with a fatal result.

Small-pox at Gravesend.—Small-pox is just now epidemic in Gravesend, where more than one hundred persons were yesterday reported to be suffering from the disease. Many fatalities have resulted, and as there is at present no provision for isolation, serious consequences are feared before it is got under.

The New Stafford House Hospital.—The Stafford House Committee have received from Mr. Kennett a report upon the new Hospital at Gallipoli, in which he says:—"I found everything most satisfactory at our hospital. The wards are of a convenient size, well ventilated, and perfectly clean. Wines, soups, and other medical comforts are found to do more than medicine towards curing the sick and worn-out soldiers. The moral effect of this hospital is extraordinary. There is scarcely a man of the 15,000 Turks in the Gallipoli lines but who looks upon it as a sign of English sympathy, for which he is deeply grateful. Admiral Commerell considers it most important that we should not close this hospital for the present." Within the lines of defence of Constantinople the sickness is rapidly decreasing. This result is, no doubt, due to the burying of 3,600 carcases of animals by Dr. Harvey's section. With the limited funds in hand the committee are still maintaining the Gallipoli and Salonica hospitals, and they feel deeply the importance of doing so, more especially the former, on account of its proximity to to the British fleet, and as a means of checking the spread of epidemics and infectious diseases.

NOTICES TO CORRESPONDENTS.

HUNTERIAN SOCIETY.—This (Wednesday) evening, at 8 o'clock, Dr. Richardson, F.R.S., will read a paper "On the Practice of Total Abstinence from Alcohol in Health and Disease." To the discussion of which he invites all members of the profession.

HARVEIAN SOCIETY.—On Thursday, April 25th, a special meeting will be held at 8 p.m., when Mr. A. J. Pepper will read a paper "On Abnormalities of Fœtal Development.

THE SALE OF DIPLOMAS.—It has been our custom to expose the names of those who engage in any illicit practice connected with the profession, and we have from time to time brought to light the sellers of diplomas, to which we now add another. The individual boasts of the name of Dr. Rumler, 40 Hollmanstrasse, Berlin, Germany, whose letter, addressed to the authorities of one of the American universities we have just seen, says: "Having acted in this capacity for several universities, I could labour for you with the best success if you would elect me as a delegate for Europe. I would endeavour to arrange matters in such a manner that the good name of your university will not suffer. I require diplomas as a doctor of medicine and as a doctor of dental surgery." The authorities of our colleges will need a more watchful eye than hitherto in order to detect these twenty-guinea diploma-holders when the Medical Acts Amendment Bill with its Dental Register becomes law.

LONGEVITY.—The widow of a labourer died last week in Whitechapel at the ripe age of 104 years. Two deaths at the age of 90 are also reported by the Registrar-General caused by falling down stairs.

PARAGRAPH PUFF.—A correspondent sends us an account of a "skilful surgical operation" at Drogheda Workhouse, published in the *Freeman's Journal*. If Dr. J. W. Adrian, whose name is used in it, were privy to its insertion he would be guilty of an unprofessional act. It is charitable to assume that the puff is the emanation of a local penny-a-liner.

TESTIMONIAL TO MR. SPENCER SMITH.—In another column will be found an announcement of the intention of past and present pupils of St. Mary's Hospital, Paddington, to present Mr. Spencer Smith, the Senior Surgeon, upon his retirement from active duties, with a testimonial in recognition of his long services in connection with this Hospital, and as a mark of the esteem in which he is held by those who have passed their educational course thereat. Subscriptions should be forwarded to the Hon. Treasurer at the Hospital.

VACCINATION PROSECUTION.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—What remedy has a medical officer when a Board of Guardians tacitly refuse to issue a cheque for one guinea, being the amount of a magistrates' order made on them for giving evidence against vaccination defaulters?

I attended court recently and refused to give evidence in vaccination cases because the magistrate would not give me an order on the Guardians for one guinea. The order was duly drawn up. Seven cases were dismissed and eight were entered no appearance.

I have heard that the Guardians intend to process me for the amount of expenses incurred owing to my refusing to give evidence. I think the amount is 19s. 6d.

Was I right in declining to give evidence? Can the Guardians recover under the circumstances?

By answering me in the next issue of your valuable journal I shall feel obliged. Yours, &c.,

G. W. T.

[1. The Guardians *must* pay if a magistrate's certificate be presented, and the money may be easily recovered on process. See decree in case of Kisbey *v.* the Boyle Guardians.

2. It would, we think, have been better, on receiving the notice to attend at petty sessions, to have written to the clerk of the union stating that, inasmuch as you could not find it within your duty as specified either in the regulations or in the Acts of Parliament, and, inasmuch as your fee for similar services on a former occasion had been refused, you were not prepared to attend the prosecution without a definite understanding as to payment.

3. In our opinion the Guardians cannot recover the expenses from you, though they might do so if the attendance was within your duty. You should, therefore, defend their process and plead that it was not your duty. Certain Boards have attempted to escape payment by alleging that they were liable, under the Act, only for "expenses," but this point has been already decided against them in Kisbey's case above alluded to.—ED. M. P. & C.]

M. C.—There is no illegality in the proposed arrangement. The Guardians, however, have the power to refuse to recognise the substitute. You also run the risk of supplanting the son in the appointment, unless you bind the assistant by a written agreement to retire after a definite period.

COMMUNICATIONS, Enclosures, &c., have been received from—Dr. Bourneville, Paris. Dr Wyckoff, Brooklyn, New York. Mr. Berry, Holmfirth, Yorks. Dr. Davidson, Chester Lunatic Asylum. Dr. M. Thomas, Glasgow. Mr. Barnard, Buxton. Dr. Harris, Norwich Lunatic Asylum. Dr. Robert Walker, Maida Vale. Dr. English, New Brunswick. Mr. Shaw, London. Dr. Milner Fothergill, London. Mr. Browne, London. The Registrar-General. Dr. Greene, Peckham. Mr. Porteus, Caterham. Mr. John Williams, London. Mr. Joy, Northwold, Norfolk. Dr. Thos. Smith, Reigate. Mr. T. E. Owen, Plymouth. Mr. Hanson, Municipal Infirmary for Diseases of the Throat

APPOINTMENTS.

ARCHER, R. S., M.B., C.M., Medical Officer for the Garston District of the West Derby Union.

BODDY, H. W., M.B., Assistant Physician to the Clinical Hospital and Dispensary for Children, Manchester.

BROWNE, C. R., M.D., Physician to the Convalescent Hospital, Eastbourne.

BUCKLEY, S., F.R.C.S.E., Assistant Surgeon to the Clinical Hospital and Dispensary for Children, Manchester.

HERON, G. A., M.D., an Assistant Physician to the City of London Hospital for Diseases of the Chest.

LYDDON, R., M.R.C.S.E., House Surgeon to the Kent and Canterbury Hospital.

PEPPER, A. J., M.B., F.R.C.S.E., Pathologist and Medical Tutor to St. Mary's Hospital Medical School.

ARMY MEDICAL DEPARTMENT.—The following were gazetted on Friday last:—Surgeon Major H. D. Massy retires on temporary half-pay; Surgeon Majors J. Atkinson and R. Spence, M.D., retire on half-pay; Surgeon Major A. R. Smith, half-pay, and Surgeon T. Kearney resign their commissions.

Marriage.

FFRENCH—WAKEFIELD.—April 11, at Kilkenny, Edward T. Ffrench, F.R.C.S.I., &c, of Glasson, Westmeath, to Kathleen, daughter of Thomas B. Wakefield, Esq., Hall Moate.

Deaths.

CAMPBELL.—On April 9, at Glentallach, Argyllshire, Hugh Campbell, L.F.P.S.G., aged 70.

CASS.—On April 12, at St. George's Road, Eccleston Square, William Cass, M.D., aged 67.

CLARKE.—On April 10, at Ballieborough, co. Cavan, Dr. Joseph Clarke, senior.

CROUDACE.—On March 10, at Thyetmo, British Burmah, Thomas Croudace, Surgeon-Major 6th Regiment, aged 51.

FLOWER.—On April 18, very suddenly, at his residence, Denmark Hill, S.E., J. Swan Flower, M.R.C.S., L.S.A.

HADDEN.—On February 17, at Skibbereen, co. Cork, David Hadden, M.D., aged 60.

MURDOCH.—On April 12, at Bruntfield Terrace, Edinburgh, William Burn Murdoch, M.D.

O'REILLY.—On April 8, at Bishops Stortford, Michael O'Reilly, M.D., aged 61.

ROPER.—On April 1, at Cambridge, Robert Roper, M.R.C.S.E., aged 54.

STEVENSON.—On April 12, at Nottingham, Frederick Stevenson, M.R.C.S.E., aged 60.

THOMPSON.—On April 18, at his residence, Notting Hill, Dr. T. Thompson, F.R.S., late Superintendent of the Botanical Gardens, Calcutta.

ON SYPHILIS AS IT AFFECTS THE BRAIN AND NERVOUS SYSTEM.

By THOMAS STRETCH-DOWSE, M.D., F.R.C.P. Edin.,

Late Physician-Superintendent to the Central London Sick Asylum, Highgate; Physician to the North London Ho spital for Consumption and Diseases of the Chest.

(*Continued from page* 255.)

DIAGNOSIS.

I am quite inclined to the belief that hyperplastic inflammation of the pia mater of the cord is not so uncommon during the second stage of syphilis. I have no pathological evidence in proof of this beyond the cases given (see cases), where this condition was associated with myelitis. The following case is typical of several which have come under my observation :—

Case XVI.—*Syphilitic Inflammation of the Pia Mater of the Spinal Cord in Lower Dorsal Region—Pseudo-Paraplegia—Recovery.*

A. B., a strongly built and healthy-looking woman, æt. 24, was admitted under my care with syphilis in June, 1876. She contracted the disease on the 16th May, 1876, and on June 1st she observed the rose-coloured rash over her chest; in a day or two it extended over the greater part of the body, and the throat then became sore. On her admission into the Central London Sick Asylum at Highgate the chancre, the rash, and sore throat were indicative enough of syphilis.

On June 31st she complained of the legs aching, so that she could scarcely drag one before the other—they felt heavy, like lead. She said that her spine ached, but there was no tenderness upon pressure. The passage of a sponge filled with hot water, and of a lump of ice along the spine made her start when it came in contact with the spine of the lower six dorsal vertebræ. The flexor muscles of the legs were exceedingly painful, and subject to violent cramps. There were no convulsive movements of the lower limbs except when she was asleep, and then she wasawakened by them. When walking, she said it felt as though she was walking upon nothing, and when made to walk blindfolded over stones, blankets, and wood, she did not experience any difference between them. There was no sensation as of a ligature or cord being tied round the body. The sphincters were unaffected.

The urine was acid, of normal gravity, and free from albumen. Reflex excitability was rather lessened than increased. (This might have arisen from exudation and pressure. We have shown from pathological examination that exudation is extremely rapid in syphilitic inflammation of the membrane at the base of the brain and in syphilitic inflammation of the membranes of the cord). Cutaneous sensation to 20 cells in 40 seconds. Muscular excitation normal. Œsthesiometric test $1\frac{4}{8}$ inch.

The treatment consisted in the application of leeches over the dorsal spine, which was followed daily by dry cupping and highly nutritious feeding with wine. The blue pill, which she was taking at the time, was not discontinued. Perfect rest was enjoined. In about three weeks she was well.

Case XVII.—*Syphilitic Congestion of the Membranes of the Spinal Cord in the Dorso-Lumbar Region—Recovery.*

E. S., æt. 38, came under my care on the 9th July, 1874. She was a woman of dark complexion and of tubercular history. There was psoriasis of the tongue and deep-seated ulcers of the pharyngeal mucous membrane, chronic periostitis of the shin-bones, and nodes over the scalp—the hair came off plentifully, her face was bloated, and the urine was alkaline and albuminous. The skin was covered with a desquamating copper-coloured eruption, and in some places rupial elevations were seen. She contracted the disease six months previous to coming under my care.

The first symptoms of paralysis was a weakness in the lower limbs, so that at times in walking they almost gave way under her. This condition gradually increased, and in a few days she was unable to walk at all. The legs felt numb and heavy, as though they were made of lead,

and she could not raise them from the bed. There was marked cutaneous hyperæsthesia, no muscular cramps, but there was intense muscular hyperalgia. No convulsive seizures, slight reflex spasms. The sphincters were never incompetent. There was no spinal deformity or rigidity of spinal muscles. There was some increased sensibility over the 11th and 12th dorsal and lumbar spines, and she complained of a dull aching pain in this region. She was ordered a mixture of bichloride of mercury and iodide of potassium three times a day, dry cupping, and counter-irritation to the spine.

For a considerable time there was no improvement—in fact, for some months. On the 20th of April the following note was made of her state: She has so far recovered that she can walk with the aid of a stick, and when lying upon her back in bed can move the limbs co-ordinately in any way, but she does so in a stiff and awkward manner. The sense of heaviness has completely passed off.

Condition of Lower Extremities.

1. Reflex excitation to tickling normal.
2. Temperature normal.
3. No automatic movements.
4. Cutaneous sense and sensibility normal.
5. No subjective sense of heaviness.
6. The muscular hyperalgia has given place to an impaired muscular sensibility.
7. No marked muscular atrophy.

Electric Condition of Lower Limbs.

Cutaneous perceptibility is not quite normal, but progressively increasing from the feet upwards. There is no muscular response to 20, 30, or even 40 cells Stohrer's continuous current.

Stohrer's Induced Current, 20 Cells to Spine.

Region.	Rate of Perception.
Cervical - - -	- 1 sec.
2nd Dorsal - -	- 3 „
4th „ - -	- 2 „
7th „ - -	- 5 „
9th „ - -	- 2 „
1st Lumbar - -	- 1 „
2nd „ - -	- 1 „

The urine is now free from albumen. The objective signs of syphilis are nowhere visible, and the patient is becoming well nourished, and, in other respects, healthy. The induced current of low power to the spine and cold douches completed the cure. She was discharged in June, 1875, having been under treatmeat for nearly twelve months.

CASE XVIII.—*Syphilitic Paraplegia.*

S. J., æt. 56, admitted October 30th, 1875, a woman of dark complexion, thin, and careworn features, says she had contracted syphilis about three years. When I first saw her there were no objective signs of the disease, beyond a posterior synechia of *right* eye from syphilitic iritis, and there was a neuro-retinitis of the *left* eye. The following notes are abbreviated :—

The paralysis commenced with a feeling of heaviness in the lower limbs, and do what she would she could not get them warm. Although the limbs were almost entirely devoid of sensation, they were agonisingly painful with (as she expressed it) "a burning pain." The legs at this time did not feel heavy like lead. She said that when walking the ground felt like india-rubber. Her memory has been failing, and she has been distracted with pain, sometimes to such an extent that she has reeled about as though intoxicated. Has never had a fit. On admission, she complained of flying pains about the joints and bones, and of a feeling of deadness of the lower limbs extending beyond the knee, and rather on the outer than the inner side of the thighs. Her power of progression is very limited, and she scuffs the ground as she goes along. There is a tender spot on the 9th dorsal spine. No feeling of abdominal girth. She was ordered a mixture of bichloride of mercury and iodide of potassium, and in the course of three months, with galvanic and other treatment, she was discharged cured.

Concerning syphilitic disease of the spinal cord and its membranes, I cannot agree with the statements made by some authors that it does occur very many years after the primary infection. Judging from my own experience, it is rare to find a true paraplegia unassociated with brain disease seven years after the primary manifestations. From an analysis of seventeen cases coming under my care, I find that three occurred during the secondary period; seven during, and co-existent with, the tertiary objective signs; four, three years after; two, five years; and only one after six years of the syphilitic infection.

We have now to consider those forms of paralysis arising from vascular syphilitic changes of the main arterial cerebral vessels which have been described by Heubner, resulting in mal-nutrition, exudation, hæmorrhage, softening, atrophy, and thrombosis. Here we find, undoubtedly, the most difficult task connected with the whole subject—so difficult, in fact, one feels inclined to set it aside altogether rather than to run the risk of drawing from it merely speculative and false deductions. If we are not sure that our patient has syphilis, but if he presents some objective signs even of ancient syphilitic invasion—as an atrophied testicle, for instance, which we may be told was once hard and swollen—and if there are no vascular changes with increased arterial tension, or signs indicative of renal disease, or ischæmia of the optic disc, or of an especial gouty habit of body, or other special predisposing cause, I think we may then fairly infer that the cerebral degenerations are due to arterial disease which has syphilis for its origin.

I have been carefully looking over a very large number of recorded cases of my own, and of others, some of which I have known to be the result of syphilis, and the rest due to vascular changes of other kinds of a most undoubted character; and I must say that I cannot quite agree with all the signs and symptoms so specially laid down by Heubner in his very excellent article on "Syphilis of the Brain" in Dr. H. von Ziemssen's "Cyclopædia of the Practice of Medicine" (I mean, of course, in regard to this especial part of the subject); yet I may say that if we have no positive evidence, we are by inference permitted from a clinical, if not from a strictly logical, point of view, to assume a syphilitic disease, even provided we have no objective sign of syphilis, seeing that the elements of other disease are absent.

In a patient suffering from symptoms of brain disease where there is no clear syphilitic history, I think the facial expression and the difference between the real and apparent age is of great importance, and more particularly if there is no other notable cachexy. In addition, also, we find the ophthalmoscope aids us in simplifying the means to diagnosis, especially in clearing up the question as to the existence of changes in the vessels from chronic renal disease, with or without atheroma, which of all others seem to me to be the most material and important. Of course, there is little difficulty thrown in our path if the patient has not only the history but the signs of syphilis upon his person. Under such conditions, if he has an apoplectic seizure, or an attack of hemiplegia with or without loss of consciousness, a paraplegia or objective signs of a lesion of a cranial or spinal nerve, we shall then be to a certain extent sure that syphilis is at the bottom of it.

It must be apparent that in the progressive, gradual, and even complete occlusion of one or more cerebral vessels, we shall have a train of phenomena varying greatly in their character, course, and termination, the functions of some centres will be depressed, whilst others will become exalted, and such states will naturally depend upon the vessels involved and the area of their distribution. Heubner has considered all these conditions with great care, but he appears to have arrived at the conclusion that changes from arterial syphilitic disease are rare in any other than the medium-sized vessels which are distributed to the ganglia at the base of the brain. My own

experience does not coincide with the singularity of this view, and I have proved that the arteries of the pia mater which serve to supply the grey matter of the cortex and the convolutions with blood are equally liable to this form of degeneration leading to softening, infarcts, and cysts. In my own cases, the peculiar form of headache has been worth observing. It is not essentially nocturnal or paroxysmal, but comes on with great severity for twenty-four or forty-eight hours, perhaps not oftener than once in three or four weeks, yet rarely in the interval leaving a perfect sense of freedom. Exacerbations may, however, be readily induced by undue fatigue, worry, or excitement. The *pain* is of a different kind to that of the other forms of headache ; it is of the dull, heavy, aching character. It has no central point from which it radiates. It is usually diffused more or less over the whole of the forehead, and gives to the patient a hang-dog look ; often the complaint is that the eyelids cannot be raised, they feel so heavy, the whole of the vessels of one eye-ball may be congested and not the other, or both may be similarly affected. There may be a ptosis of one lid, and in the course of twenty-four hours this may have passed off and given rise to a ptosis of the opposite lid. There may be an external squint of one eye and an internal squint of the opposite eye, yet, in twenty-four hours muscular co-ordination shall be normal. There may be temporary diplopia and coloured vision associated with other ocular troubles, as well as nausea, vomiting, constipation, deafness, and various noises of the ear, which may be associated with a persistently furred tongue, and which must not lead us into the error that the stomach is the seat of the derangement. Heaviness and lethargy, rather than drowsiness and somnolence, are to be noticed. The tongue may be divergent or tremulous, or the patient may not be able to protrude it beyond the teeth. The speech may be slow, hesitating, and even aphasic, with unilateral or bilateral facial spasm. Cramps and convulsive spasms of isolated or combined groups of muscles with or without a local paresis, or an actual paralysis of one limb, or of one-half of the body, may arise and rapidly subside ; and it is to be remembered that, as a rule, the subsidence of these signs and symptoms is rapid, whilst their invasion is comparatively slow. This is peculiar to syphilis, and, again, syphilitic paralysis may occur during the night, the daytime, or early morning seem to be associated with these manifestations. A man free from syphilis goes to bed, and overnight has felt quite well, but finds in the morning that he cannot move his arm or leg. This mode of attack is surely not the case where the lesion is due to syphilis. A syphilised patient, without premonitory warning of any especial kind, may have an epileptic fit, but he will not without warning fall in an apoplectic fit. This does not imply that he will not have a fit of apoplexy ; but for some days, or it may be weeks, previous to this calamity, he will be heavy and lethargic, although he is not able to sleep ; he is restless, and all his doings and movements are without any definite purpose ; he may not eat unless requested to do so, or if he sits down to partake of a meal he rises before he has finished, and his knife, fork, or glass may suddenly fall from his hand, or his hand may shake so that he is unable to carry a glass to his mouth, or if he does so it rattles against his teeth and the fluid escapes at the corners of his mouth, of which he is in a measure unmindful, and finally, he may neglect and appear to be regardless of the calls of Nature. It is after symptoms such as these that the man with syphilitic arterial changes is usually found breathing stertorously and in a comatose apoplectic state. There may be subsequent convulsions or there may not, and the comatose state may be slight or it may be profound ; the comatose condition is the more usual, and it resembles a deep stupor, out of which the patient may be roused by pinching or pricking, to a state of apparent subjective consciousness, which is only a grade, however, beyond the mere automatic. He may continue in this state for one or two weeks, or, as I have seen cases, for three weeks, and then with returning consciousness the paralysis disappears, the intellect brightens, and he may even for a time so far recover as to be able to attend to his business or professional pursuits, but after this there is rarely a return of the evanescent forms of paralysis previously noted. After an attack of this nature, when paralysis supervenes (and it is very rarely that it does not sooner or later) it is usually persistent and permanent, and death may take place during an attack similar to that just noticed, or it may be preceded by a series of epileptiform seizures ending in profound coma. I give the following interesting case from my note-book as a typical one of syphilitic arterial disease :—

Case XIX.—*Case of Defect of Speech from Syphilitic Brain Disease, with Fits of Partial Unconsciousness and Alternate Paralysis, sometimes of all the extremities, sometimes of the left leg only, but usually of the right.—Recovery.*

S. S., æt. 46, came under my care in August, 1876. He was a man of good physique and fairly healthy facial aspect. From his history, it appeared that for the last three years he had suffered from headache, that his memory had failed, and that upon two or three occasions he had some kind of fit. I examined his body for traces of old syphilis, but none were found except a hard nodular atrophied condition of the left testicle. The optic discs were quite healthy ; the radial arteries soft and compressible ; urine clear, of acid reaction, and free from either albumen or sugar. Sp. gr., ·1018. He said that he had been under Dr. Elam's care at the hospital for paralysis, and had improved greatly. He had been ill for some time before he was paralysed ; the paralysis commenced with gradual loss of power in the *right* arm, then the *right* leg became weak and his speech was affected; shortly after this the same condition of paralysis affected the *left* arm and the *left* leg. He became giddy, fell about, and forgot himself ; his memory was so bad that he could not remember what he wanted to say, and the articulation was so defective that he could not make himself understood at all. He said that the power of movement returned in equal ratio with the memory and speech.

August 31st.—Since he has been in this asylum he has improved very much ; the memory is now good. All the cranial nerves are normal except the ninth. There is very marked want of voluntary co-ordinating power over the tongue ; when he tries to direct its movements it is some time before he is able to do so, and then they are not tremulous, but spasmodic and jerky; there is perfect voluntary power over the lips, but no ataxy or tremor of the limbs. Beyond the defect of speech and slight imbecility, nothing of note appeared to ail him.

September 10th.—Is not so well ; he complains of a return of the pain in the head, is obtuse, memory very defective, walks as though he was fearful of falling, does not care to get out of bed, says that he sees double, and things look blue ; fancies that he hears strange voices calling to him, says that some one is at the foot of the bed going to murder him. These exacerbations come on at night, but during the day he is very lethargic, and it is with some difficulty he can be roused to take nourishment. No control over sphincters.

16th.—I was called to him at 6.30 p.m., and found him sitting up in bed and screaming out "murder" at the top of his voice in a very excited state ; he tried to get out of bed, but fell upon the floor ; although his eyes were wide open he took no heed, neither did he seem to know either myself or the nurse. Pinching made him more comprehensive than anything else, so that sensibility was not much interfered with. Soon after this, he became slightly comatose.

17th.—Has been quiet all night ; is lying in bed with the eyes open. Pupils dilated, no apparent objective consciousness. Urine drawn off ; bowels relieved by enema. Cold to the head ; sinapism to calves of legs, and hot water to axilla and feet. Of the cranial nerves, the 1st,

2nd, 4th, 5th, and 6th are normal. There is palsy of the left 3rd, and right 7th ; the 9th doubtful ; there is right hemiplegia and paraplegia ; he seems to exercise voluntary power over the left arm. Pulse 130 ; resp. 40 ; temp. in right 102·3 ; left, 101·6, evening ; right, 102·4 ; left 101·2.

18th.—Has been quiet all night, and is in all respects the same as yesterday. Urine drawn off.

19th.—His state of consciousness seems uncertain ; he appears to have lost voluntary power over the left arm ; yet the actual voluntary power which he possesses is doubtful ; electric stimulus excites both voluntary and reflex movements ; the facial paralysis has disappeared ; resp., pulse, and temp. are now normal.

20th.—This morning he is conscious when roused, and makes an attempt to answer questions ; takes nourishment freely.

25th.—Is perfectly conscious and rational ; no *objective paralysis*, but a weakness of the *left* half of the body. He is now out of bed, and walks fairly well. The speech is much more distinct than before the seizure, and the movements of the tongue are co-ordinate ; no pain in the head, or giddiness. He was ordered a mixture of bromide of potassium, iodide of potassium, digitalis, and conium, to be taken three times a day. I kept him under observation for some months, although he repeatedly requested me to give him his discharge, saying that he was quite well. This case is typical of vascular occlusion from arterial change, and thrombosis producing general disturbance in the current of the blood, and cerebral shock. Dr. Huebner states, in speaking of these diseased vessels of the brain, that the resistance to the blood current in tubes thus narrowed increases considerably and proportionally to the length of the narrowed portion. Hence, a useless consumption of the momentum of the blood current, the consequences of which are intensified by the fact that with the diminution of the elastic force in the arterial wall, a subtraction takes place from the sum of the forces which tend to propel it. The blood therefore moves more slowly and with less tension in the network of the pia mater and in the brain capillaries.

Here it seems to me we have found the key to understanding the peculiar somnolent or drunken-like conditions in which the cerebral functions are not lost but greatly interfered with.

THE GOULSTONIAN LECTURES
ON THE
LOCALISATION OF CEREBRAL DISEASE.

Delivered before the

ROYAL COLLEGE OF PHYSICIANS OF LONDON,

By DAVID FERRIER, M.D., F.R.S.

[AN ABSTRACT.]

IN this, the third and concluding lecture, Irritative Lesions of the Motor Area were first described. The seat of these lesions may be approximately determined by the rules laid down as to the localisation of destructive lesions, but only approximatively, as the diagnosis of the seat of an irritative lesion is naturally more uncertain, owing to the difficulty of determining the extent of the zone, or the special point in this zone in which vital irritation concentrates itself. Yet many cases are on record in which the phenomena of irritation have been such as to allow exact regional diagnosis in accordance with the principle of localisation of distinct centres. Such irritative lesions consist of hyperæmia and irritability of the cortex and adjacent medullary tracts, as had been noted by several observers. Or there may be actual inflammation, or a morbid growth.

Frequently the disease, which commences as an irritative lesion, tends to invade and destroy the region on which it grows, and leads to permanent paralysis, with secondary degeneration, irritative phenomena being liable to occur so long as the vitality of the grey matter and subjacent medullary fibre has not been absolutely annihilated. "Jacksonian epilepsy" has often, in the early stages, the character of a monospasm, which may extend to more general convulsions. When both sides become so affected, the convulsion goes down one side and comes back up the other, according to Dr. Hughlings Jackson, but he had not yet been able to establish this in his own experience. These monospasms may be crural, brachial, or facial. Illustrative cases were related. Thus, in a case where the right leg was specially affected, a tumour was found in the upper posterior part of the left frontal lobe, extending forward into the posterior part of the first and second frontal convolutions. In a brachial monospasm convulsions invariably began in the left thumb, and after death a tumour, the size of a hazel-nut, was found under the grey matter at the posterior extremity of the third frontal convolution of the right hemisphere. Then, as to facial monospasm, the lecturer said few uncomplicated cases had been recorded. In a case related by Dr. Bramwell, a woman who had received a cranial injury began to have right-sided convulsions, followed by paralysis of the right arm and leg. She remained subject to frequently repeated convulsions, which always began in the right platysma, and frequently were almost entirely confined to that muscle. On *post-mortem* examination a spiculum of bone from the inner table of the skull was found projecting and causing a very limited lesion of the inferior margin of the ascending parietal convolution. Clinical and physiological experiment are here, again, in harmony.

The lecturer then proceeded to the consideration of Lesions of the Sensory Regions. He said, "It is clear that if the centres of sensory perception are localised in the hemispheres, these are to be sought in those regions yet remaining to be considered, viz., the occipital and parieto-temporal lobes. Too much reliance should not be placed on anatomical investigation as a means of determining cerebro-spinal tracts ; still, it was pretty generally recognised that the posterior strands of the crus and their connections with the brain and cord, were more specially the paths of sensory impressions. Experiments show that when a section is made of the posterior capsule there ensues a condition of hemianæsthesia of the opposite side of the body, with frequently some temporary loss of motor power ; whereas, when the anterior part of the internal capsule is divided, motor paralysis, unaccompanied by sensory paralysis, is the constant result. The facts of human pathology are no less precise. Motor hemiplegia is invariably the result of destructive lesions of the anterior two-thirds of the internal capsule, which may be accompanied temporarily by hemianæsthesia if the lesion be such as to cause pressure or functional disturbance of the posterior third ; while destructive lesion of the posterior third of the internal capsule causes cerebral hemianæsthesia. After reviewing some facts connected with loss of or disturbance of vision, connected with cerebral disease, he said that when there was amblyopia, or diminution of the acuteness of sight, and a remarkable contraction of the field of vision, especially as regards the perception of colour, ophthalmoscopic examination reveals no organic lesion or degeneration of the optic nerve or retina—in the first instance, at least—any atrophic changes which may show themselves subsequently being the consequence, and not the cause, of the blindness. In hemiopia the lesion is situated below the cortex.

Of lesions of the occipital lobes he said that, in injury to such lobes in the monkey, the special senses were not impaired, and the the animals retained the power of voluntary motion. The animals, however, ceased to eat — an occurrence, he thought, causally related to the lesion, as it was not found after injury to other portions of the brain. Cases supporting this view were related of disease in the occipital lobes, which were not accompanied by loss either of motion or sensation. Both Hughlings Jackson and Bastian think that lesions of the occipital

lobes are more frequently associated with insanity than lesions of the anterior or other portions of the brain ; and the lecturer said, if our feelings are our chief motors, it might readily be allowed that lesions of the anatomical substrata of such an important element of our feelings and emotions should lead to mental derangement.

Of lesions of the parieto-temporal regions, it was stated that there existed individually differentiated centres of special sense, injuries to which produced impairment or paralysis of sensation on the opposite side of the body. This had been peculiarly demonstrated as regards vision. The lecturer gave an account of his experiments on monkeys, after which some cases were referred. In disease of or injury to these areas, there is no loss of motility or sensation, though consciousness may be deeply affected. Charcot and Pitres give a case where there was dementia with great itching of the abdomen, and where there was found a patch of yellow softening in the left hemisphere, occupying the first and second occipito-temporal convolutions. Recent observations had demonstrated that in chronic epilepsy there are very commonly lesions of the hippocampus. Optical illusions, coloured vision, are frequently associated with lesions of the posterior lobes. It has been observed, too, that in cases of thrombosis of the posterior cerebral artery, vision is impaired on the side of the motor paralysis. Hughlings Jackson states very positively that he has never met with deafness as the result of disease of the cerebral hemispheres directly. Unilateral lesions of the sensory centres vary considerably as regards their effects on sensory ideation, according as the lesion is on the side of the more or less developed centre. As to loss of smell, it was often the result of blows, especially on the vertex or occiput; and instances of loss of smell and taste after cranial injuries furnish clinical corroboration of physiological experiment. As to tactile sensation, it was very difficult to localise it. Motor paralysis and tactile anæsthesia were often found together ; there is, however, no organic fusion of the motor and tactile centres with each other. There is some evidence that lesions in the neighbourhood of the hippocampus affect tactile sensation. The lecturer concluded by saying that though the clinical evidence is yet comparatively scanty, still so far as it goes it tends to bear out what experiment has ascertained as to the localisation of functions in the brain ; and that more exact observations in the future will probably go far to clear up the doubts and obscurities which still surround this important subject.

Clinical Records.

MERCER'S HOSPITAL, DUBLIN.

Under the care of Mr. E. STAMER O'GRADY.

AMONGST the patients whose cases came to a conclusion in the surgical wards during the month of March were the following :—

Excision of the Head of the Humerus, and subsequently of the entire Scapula.—Preservation of an excellent Limb.—This extensive operative procedure, necessitated by caries and necrosis, was performed "*en deux temps.*" In the first instance the head of the humerus was removed, and the affected portions of the scapula gouged away. Much temporary improvement to health supervened, but this local repair was only transitory, and after a time it became evident that extensive disease was progressing in the scapula. At the operation this bone was found in such a condition as to require the removal of the entire of it. The patient, aged 25, who had been much debilitated by long-continued suffering and suppuration, was in a precarious enough state for some time ; the natural buoyancy, however, of his constitution prevailed, and he made a most satisfactory recovery, leaving hospital with the wound thoroughly healed, the parts recovering tone, and every fair prospect of a good useful limb.

It may be here mentioned that in another case from whom the same parts had been removed some years previously, the condition of the limb continued steadily to improve with the lapse of time, being, with the exception of overhead movements, for all the ordinary purposes of life scarcely inferior in utility to the sound limb. The future of this second case seems to be at least equally promising.

Fracture of Sternum.—Recovery.—This accident occurred in a large and powerfully made man, 40 years of age. He fell under a moving heavily-laden float, and his thorax became wedged between the ground and the thick iron axle beneath the body of the cart. The displacement was very marked, the bone being broken at or about the junction of the manubrium and gladiolus. This latter portion was forced considerably backwards, the cartilaginous structures on both sides forming a somewhat depressed pair of planes leading to it. There was a profound shock and subsequently intense distress. In a few days broncho-pneumonia of an aggravated form developed. The man kept good heart all through, and surviving a prolonged struggle began to get the better of his trouble. After a stay of 58 days, he was sent from the hospital to the country, still a weakly and shaken man, but with fair apparent prospect of ultimate recovery. When leaving the hospital a depression still existed at the seat of injury, but the natural resiliency of the structures here had to a very great extent caused the deformity first observable to disappear.

Fracture of Pelvis—Perforation of Intestine—Death.—During his brief time in the hospital this case was under observation, coincidently with the preceding one. The accident was caused by a rearing mare falling over on her rider, a lad of 17. Two days after the occurrence, he was brought to the hospital. There was then extensive blood extravasation into the upper portion of the left thigh, buttocks, abdominal parietes of the same side, as well as into the scrotum. Some preternatural mobility of the hip was noticed to exist, but in the patient's state no searching examination was made. The belly was tympanitic and distended, and the face was suggestive of probable severe internal lesion. Matters went from bad to worse, death occurring the sixth day after the accident. At the autopsy gas escaped on opening the peritoneum, some feculent fluid was found in the pelvic region. A large quantity of thick inflammatory deposit was on the lower coils of the small intestine, and of the parietal peritoneum. Fourteen inches from where the small intestine terminates in the cæcum it was perforated by a double opening with clean-cut, well-marked edges. The left os innominatum was extensively comminuted, one fracture running from above through the acetabulum and into the thyroid foramen. The neighbourhood of the symphisis pubis was also broken in two places, and the isolated piece of bone displaced in such a manner that its sharp inferior fractured edge was turned, projecting directly backwards into the abdomen. There could be scarce any doubt that it was by this the lesion to the gut was occasioned. The urinary apparatus escaped unhurt. There was no intra-peritoneal blood extravasation, though such was extreme in and between the muscular structures.

Large Hæmorrhoids—Application of Clamp and Cautery—Hæmorrhage and Ligature.—The piles were "intermediary," of very large size on one side, occurring in a tailor, aged 50. Whilst applying the cautery and towards the conclusion of the process the screw of the clamp slipped. Smart hæmorrhage at once started ; the mass was transfixed by a needle carrying a double ligature, and tied in halves with strong silk. The case did excellently, the patient leaving the hospital in ten days with the parts already nearly healed.

Deep Abscess in Popliteal Space.—This case was of special interest in consequence of the difficulty of the diagnosis. The patient was a girl, aged 11. There was scarcely any ascertainable history. During the earlier days sh was

under observation the treatment was tentative. As soon as there was room to believe in the presence of pus, a long exploring needle was inserted and matter found at a considerable depth. Free vent was given to it. The subsequent suppuration was tedious, but by careful support and dressing the parts were again firmly consolidated after some weeks.

Double Hare-lip—Extensive Complication—Good Result.—Patient was a female infant aged 6 months. The mucous membrane having been stripped by knife and raspatory from the outer surfaces of the protruding intermaxillary bones, the corresponding aspects of the opening of the maxillary cleft on each side were similarly treated. Then the upper connexion of the displaced bones was partly cut through: it was now found the anterior portion of the bone was a separate and loose piece; this had to be unavoidably taken away, as well as teeth which were exposed and more or less detached. The remainder of the protruding bone, still of considerable bulk, was forced down into the place prepared for it and united there by interosseous sutures of carbolised catgut. The soft parts were dealt with in the ordinary manner. An excellent result, including a comely septum, followed.

Ugly "Gap" after Operation for Hare-lip—Remedied by further Operation.—The patient, a girl 12 years of age, had been operated on several years previously for bad complicated hare-lip associated with an aggravated cleft palate. This operation had in the main succeeded, but an ugly gap deeply notching the lip remained. Incisions were made in ∧ form parallel to the edges of the gap, meeting each other above, but not cutting through the free border of the lip below. The partially separated portions were drawn down, and the wound brought together with two small pins and twisted suture. Collodion was subsequently applied; the silk fell off two days after the withdrawal of the pins, showing the deformity to be thoroughly remedied.

Long-continued Laryngismus Stridulus, with Croupy Complication, eventuating in recovery.—A male child, 4 years old, was admitted with well-defined laryngismus stridulus associated with paroxysms of marked croupy character recurring at short intervals. This state continued for six days, during which the infant's condition was at times so bad as to suggest the serious contemplation of tracheotomy. Without obvious cause, the little patient now began to show signs of improvement, and two days later was so well that he was taken home by his mother, where, according to the report, he continued to progress favourably towards a speedy recovery. The treatment was at first emetic and mercurial, subsequently tonic and supporting.

Partial Enucleation—Uterine Fibroid—Fatal Result.—A single woman, aged 35, had been under treatment several months "off and on" for uterine tumour. The course of the disease had been steady and rapid enlargement, the patient all the while continuously losing health and strength in consequence of increased suffering and repeated hæmorrhages. Thus she had come to be in a very weakly state when operated on. After preliminary dilatations of the uterine canal with sea-tangle, the fibroid growth [which was in the substance of the anterior wall of the uterus and about the size of a cocoa-nut] was cut down on, and partly by the finger and partly by instrumental aid the mass was for the greater portion of its surface detached from the enveloping uterine tissue. In the weakly condition of the patient, it was deemed inadvisable to prolong the operation to effect the complete separation of the growth. The interference proved to have been undertaken too late—death, due to exhaustion, occurred next morning. At the autopsy it was found that no mischief or perforation had been done to the uterine walls; about two-thirds of the tumour had been enucleated. Had that patient survived there could be but little doubt of the speedy extrusion and separation of the growth by the purposed after-treatment with ergot.

Amongst various cases of minor operations were four, in which circumcision was necessitated; in all the procedure was done practically after Ricord's mode.

Phymosis an Obstacle to Connection—Circumcision.—This patient, aged 29, had been five years married, and having no family, sought relief from a very tight congenital phymosis, which he alleged "interfered" with his "duty" to his wife. The little wound healed kindly in a few days. In the other cases, respectively aged 20, 21, and 23 years, the operation was indicated for the relief of syphilitic complications; in all three there had been a more or less marked pre-existing condition of phymosis. In two of these cases no vessel could be found to ligate at the time of the section, and in both of them there was troublesome hæmorrhage a few days after it. This yielded to styptics and continued pressure.

Extensive "Sloughing Phagedæna" occurred in a lad of 20, who suffered acutely from pain and hæmorrhages previously to applying at the hospital. The prepuce was slit, and strong nitric acid freely applied. This associated with opiate and tonic treatment acted like a charm. The sloughs separated without further mishap, and the parts rapidly healed in, with, however, extensive loss of substance to testify to the severity of the affection. A few other minor operative cases requiring treatment in the house were also amongst those patients who were discharged during the month. These were—

A Cancer of Lip—Removal of Great-toe-nail and Amputation of the Index Finger.—In the case of the first of these patients the disease was of small size on the left side of the lower lip of a man, aged 63; it was removed by V incision, united by hare-lip pins and twisted suture, and healed rapidly. The second patient was a young man, aged 17, who suffered from very bad ingrowing great-toe-nail; this was evulsed by Maisonneuve's extractor. For the week he remained in hospital progress was all that could be desired. On the last patient the left index finger was removed immediately below the meta-carpo-phalangeal articulation for gangrene, following a bad smash of that digit, occurring in a wild lad, aged 15, a machinist by occupation. After a few days the parts were healing nicely, and the lad became an out-patient.

Transactions of Societies.

DUBLIN MEDICAL SOCIETY.

THE Sixth Meeting of the Society for the Session 1877-78 took place on Wednesday evening, April 3rd, the President, Dr. GORDON, in the Chair.

Dr. F. J. BANKS was elected a Vice-President of the Society.

The first business was the exhibition of patients, the subjects of interesting forms of disease.

Dr. HAYDEN brought under the notice of the Society a case which he considered would be of some interest to the members. It was that of an adult and boy, æt. 19, with

CONGENITAL ATROPHY OR ARREST OF DEVELOPMENT OF THE RIGHT UPPER EXTREMITY.

The members would observe, on looking at the patient, that there was a very striking difference, indeed, in regard to the length and volume of the two upper limbs. It would also be observed that there was a very singular curvature of the cervical portion of the spinal column, that there was a curve convex to the right side, and a curve compensatory of that towards the right side. He was not prepared to say whether the latter was the original curve, and that the cervical curve now so very striking was compensatory of the other. The patient stated that, as far as he knew at the time of his birth, he was strong and well-developed, and in good health for some time afterwards. About a year after his birth he had a fall from the table, and from that time it was noticed by his mother that he exhibited a weakness of the right upper extremity, and was ill for five years, but it was not clear what the character of his illness was. He would now read for the members the measurements of the two upper extremities made by his friend Dr. Gunn: The patient's height was, it might

be mentioned, 5 feet 4¼ inches. The scapula, from the superior angle to the anterior angle measured on the left or unaffected side 6½ inches, while on the right or affected side it was but 4⅞ inches. From the superior angle to the acromium on the left side, it was 5 inches, and on the right 4¼, so that there was a difference of 1⅝ inches in the former, and of ¾ of an inch in the latter case. From the inferior angle to the acromium there was a difference of about an inch in the length of the clavicles in favour of the left. From the top of the acromium to the outer column of the humerus there was a difference of 3½ inches—that was to say, that the left humerus, measured from the acromium to the outer condyle, exceeded in length the right by 3½ inches. The ulna, measured on the two sides, exhibited a difference of ¾ of an inch in favour of the left. Singularly enough, the two radii were the same length, each being 9 inches long, but there was a difference of ½ an inch in the length of the hands. In the circumference of the arm, at the middle of the biceps, there was a difference of 1⅝ inches in favour of the left. The forearm, measured 3 inches below the elbow, exhibited a difference of 1⅜ inches in favour of the left. The length of the limb, measured from the top of the acromium to the top of the middle finger, showed a difference of 3¾ inches in favour of the left. If they compared this with the difference between the inner spaces, the two sides, the tip of the acromium, and the outer condyle, they would see that there was only between the two a difference of ¼ of an inch, from which it followed that the difference of the length of the two limbs was due mainly to the difference in the length of the two humeri. In Dr. Humphrey's well-known work the length of the humerus in a person 5 feet 6 inches was given as 12·54 inches, while in his (Dr. Hayden's) patient's case it was 12 inches on the left side and only 8½ on the right side. Dr. Hayden remarked that the patient had been under treatment by means of the magneto-electric machine. At first his muscles did not respond, but now they did, and he found that he was acquiring some little power in the arm. The right side of the patient's trunk would be observed to be less developed than the left. He had no grasping power in the right hand, and although he knew how to write he could not do so on account of the inability to use the right hand. That the boy was fairly intellectual might be inferred from the fact that he had gone through the greater part of the first book of Euclid, and had mastered it fairly well. The lower extremities were not affected in any way.

The patient was then examined by the members present.

Dr. NIXON exhibited a patient suffering from

CYANOSIS.

The particulars of the case were, he said, briefly as follows :—The patient was a boy, aged 11 years, whose mother and two sisters had died of phthisis. About three years ago he complained of attacks of pain in the cardiac region, dyspnœa, and neuralgic headache. At that time the cyanotic condition developed itself. A short time afterwards the boy became subject to fainting fits, and it was to get relief for these that he presented himself at hospital. These fainting fits lasted for about five minutes at a time. He (Dr. Nixon) might now mention the patient's condition on admission. On examining the heart they found that there was a considerably increased area of cardiac dulness upwards and to the left side, but the sounds of the heart presented no abnormal phenomenon. There was no murmur whatever. The temperature ranged from 95° to 96°. They could observe that there was a very marked cyanotic condition of the head and neck, and the condition of the tongue was most marked. He examined the optic discs with the ophthalmoscope, and found that the edge of the discs could hardly be distinguished from the retina. The veins were extremely engorged, and very tortuous, looking like a number of snakes crossing the field of the retina. About three weeks ago a number of purpuric patches developed themselves at the extremities, but they had disappeared. The patient had, however, since then been subject to attacks of epistaxis. The boy complained of no cough, and there were no pulmonary signs, respiration being normal both at the front and back of the chest. The boy's left forearm was deformed. It was considerably shortened, and there was only one bone, which terminated in some bones at the wrist. As regarded treatment, he might mention that he first tried peroxide of hydrogen and inhalations of oxygen, but they seemed to have no effect.

Dr. M'SWINEY inquired what was the nature of the fainting fits ; were they fits or convulsions ?

Dr. NIXON said they were fits of *pseudo*-apoplectic character.

Dr. FINNY asked, was there any cyanosis of the lower portion of the body ?

Dr. NIXON replied in the affirmative. There was a dark hue.

Dr. D. M. WILLIAMS, of Liverpool, physician to the Liverpool Hospital for Consumption and Diseases of the Chest, then read a paper entitled,

A FEW REMARKS ON THE TREATMENT OF PLEURISY AND EMPYEMA.

Dr. WILLIAMS gave a brief history of the first case, which had been already reported in full in the *British Medical Journal* of December 12th, 1874. In that case he washed out the pleural cavity daily for thirty-one days with a weak solution of sulphurous acid, as the patient preferred it to the carbolic acid, which he used two or three times. He must mention, however, that there was no real improvement up to the twentieth day after the operation, the pus being still very offensive ; he therefore enlarged the wound with a probe-pointed bistoury, and, on washing out the pleural cavity, the wound became suddenly blocked, and he managed to remove two pieces of false membrane (?), horribly offensive, after which the whole aspect of the case changed, and the patient slowly, but steadily recovered. After detailing several cases, Dr. Williams said he would not now occupy time in recording the histories of cases of pleurisy with serous effusion, but only remark that they usually took from six weeks to six months' time before the fluid was absorbed, if it had been thrown out in any considerable quantity ; but, notwithstanding the longest time (three months), such cases have done well in his practice, the lung expanding once more. He felt, therefore, encouraged to treat these with diuretics, iodine, &c. Nevertheless, as an illness of two or three months was often a very serious matter to the patient, sometimes causing the loss of employment, or of business, he had asked himself if there was no way by which they could hinder the effusion of serum, or at least, its accumulating in any great quantity. When they remembered that the sharp stitch in the side in pleurisy, caused by the friction of the two surfaces, was intended to limit the movement of the lungs, we could not but feel that Nature had already given them the hint—stop respiratory movements and the mischief is prevented. They had already recognised that principle in peritonitis, synovitis, &c. Here, however, they had to do with an organ whose function could not be stopped with safety to the patient ; but he thought they could sufficiently limit the movements of *one* lung so as to hinder the formation of, at any rate, a large quantity of fluid in the chest, and this he had attempted to do by strapping the inflamed side firmly with plaster, taking care to bring the ends of the plaster to the opposite side of the spine and sternum. The first result of such treatment was a great relief from pain ; the next was a subsidence of fever, &c. To say that a few cases had been thus treated successfully was to prove nothing, as it might be reasonably urged that these were slight ones, or only dry pleurisy ; a medical friend, however, had, at his request, already treated eight successive cases successfully. Having detailed one case treated successfully in that way, Dr. Williams said that since writing the description of that case he had heard that an American surgeon had claimed all thoracic diseases for the domain of surgery, and treated all such by pressure, but not exactly strapping, while Dr. Fred Roberts had, he found, already advocated strapping. Again, with reference to empyema, he wished to dwell especially on the condition of the lung after recovery. It is pretty generally admitted that in children under twelve years of age, such cases usually ended well—the lung expanding again, whatever may have been the amount of mischief ; while in adults this was rarely the case, the lung being almost always so damaged as to be unable to support life *alone*. This is surely not a *cure* in which we can take much comfort, however brilliant the recovery might appear to the patient and his friends. On the contrary, they should not consider such cases *cured* unless the lung once more occupied its normal situation. He had asked himself the reason why the lung should expand so easily in children, and scarcely ever do so completely in adults ; and he thought the condition of the ribs in children explained it. Thus, in children the ribs yielded rather readily to the atmospheric pressure without losing their spring ; consequently there was not left the same amount of empty space in the chest when the fluid was removed as in an adult, while, at the same time, there was a constant suction power from the tendency the ribs had to resume their

natural curve. In the adult the ribs yielded much less readily, but eventually became bent in permanently. Now, it had occurred to him that if they could imitate this, and find some plan of keeping the pleural cavity more or less constantly in a state of vacuum before the ribs bent without using injurious force, they would help the lung to expand; and for this purpose he had invented a canula with very delicate valve, which, by acting only one way, allows fluid or air to escape from the chest, but instantly hinders air entering it. Now admitting that a patient, with this tube *in situ*, coughs only twice each hour, the force of coughing easily expels fluid out through this tube, while the valve effectually hinders the entrance of air into the pleural cavity. Thus more or less of a vacuum is formed, and in proportion to the amount of vacuum was the aid given to the air rushing through the trachea to expand the lung. The canula had been purposely made short, in order that it might be worn until the lung expands pretty freely. It is secured in its position by tapes passed through the slits on either side. Seeing, then, that pleurisy, if detected at the commencement, may be greatly relieved, and effusion to any great extent hindered by firm strapping, it became exceedingly important to detect it early. There was, of course, no difficulty in doing this when effusion had already taken place, but previous to that he considered it no easy matter to do so in children. The pain in the side and friction sound, upon which they depended so much in the adult, were of but little use in dealing with children, and he had adopted the following plan:—Suppose a child two years old; very cross and feverish, with a slight cough, and these symptoms not explained by any other disease. He wrapped the child loosely in a blanket, and having put it sitting on its mother's knee, waited a minute or two; presently it coughed, and immediately cried. Then he put it sitting upright, and watched carefully; next time it coughed they would notice that it shrank to one side. He placed a warm flannel on that side, and let the mother keep up firm pressure; the child coughed again, but the crying and shrinking were less; and if on very careful examination there was slight dulness, and respiration a little feeble, without crepitation, they might be sure that they had a case of pleurisy; and if that side be strapped the child would probably have a good night, and be much better next morning. Supposing effusion to have already taken place (and the patient be a child), the fluid should be removed at once *if the constitutional disturbance is great*, as in all probability it is purulent—serous effusions giving comparatively little indication of their presence unless the quantity of fluid is great—indeed, he had been often surprised at the small amount of constitutional disturbance where he had found a large quantity of fluid, in both children and adults. If a doubt existed, the needle of the hypodermic syringe might be used to explore, as recommended by Dr. Barlow and Mr. Parker; but in an adult he would seek to be guided entirely by the constitutional disturbance, which, he thought, was much greater where the effusion was purulent. If, in a child, a fistulous communication with a bronchial tube had already occurred, and pus was being freely expectorated, he would first strap the side and wait a few days, as that seemed to be Nature's best and most successful mode of removing pus from the cavity of the pleura (while fistulæ through the thoracic parietes almost always ended badly). Should the relief be insufficient, or the strength giving way, he would then tap the side; but, in the case of an adult, he would tap at once, notwithstanding that a fistula had occurred, as he had not seen a single such case do well without tapping. The pleural cavity should be freely washed out with a weak solution of carbolic or sulphurous acid, or iodine, and if, after a week or two, the pus remained fœtid, the wound should be enlarged with a probe-pointed bistoury, in order to give exit to any pieces of false membrane or clots of blood which might be decomposing. There was nothing remarkable in the cases he had detailed; their interest lay rather in the fact that they were all more or less frequently called upon to treat them. Nor was there much that was new in the treatment advocated, except it be the valved canula, which, he hoped, some present would put to the test.

Dr. HAYDEN wished to express the indebtedness of the Society to Dr. Williams for coming over specially from Liverpool to read the paper with which he had just favoured the Society, and also for the great merit which the paper itself possessed. All who had been connected for some years with important hospitals had, doubtless, had great experience in the treatment of effusion into the chest in its various forms. With most the results had been in the majority of cases unsatisfactory. Latterly, however, men had taken heart, and they had done what common sense, so valuable a guide in many other particulars, would have suggested, namely, removed by mechanical means the body which was interfering with the vital functions of breathing. Dr. Williams's remarks on the treatment of serous effusion possessed considerable interest. He (Dr. Hayden) could not subscribe to his approval of the treatment of effusion by means of opium, for he (Dr. Hayden) had never seen any benefit from that treatment—in fact, he would regard opium under such circumstances as merely a palliative. He had had some experience of tapping the chest in cases of effusion, and he believed that where the effusion was serous, where it had been the result of acute inflammation, where life was threatened (especially in a child) from the mechanical pressure of the fluid, having tried the ordinary means of quickening the action of the kidneys and bowels, and having failed by that means to relieve the patient or to alleviate the symptoms, there should be no time lost, but at once the operation of tapping should be performed. He had had within the last ten days an opportunity of putting that doctrine into effect in the case of a boy four years of age, who had been a fortnight ill. When he saw him the left pleural cavity was quite full of liquid, dulness was universal, the heart placed to the right side, congestion of the face, the pulse beginning to fail, and the patient was beginning to get cold. The operation was at once performed, and a quart of fluid removed. Immediate improvement followed, the heart returned to its place, and within three days the boy was running about quite well, and from that time he had gone on improving, and was now quite well. Dr. Hayden then exhibited a portion of the fluid (removed from the patient referred to), in which twenty-four hours after removal a mass of fibrine had formed.

Dr. HENRY KENNEDY would like to ask Dr. Williams if he had met with any unpleasant results from washing out the pleura with fluids? He (Dr. Kennedy) had met with in the periodicals records of cases in which sudden death was the result of the use of carbolic acid and materials of that kind in the way described by the reader of the paper, and he therefore would be glad to know if anything of that kind had happened to Dr. Williams. Dr. Kennedy then stated that he had met with two cases in which the fluid removed by tapping was of the most fœtid description. He had always observed in such cases that the fœtor of the fluid seemed to be in connection with the state of the body for the time being—the body being below par in general health.

Dr. FINNY said there were two points in connection with the treatment that he looked upon as very important. One was strapping, which had been known in Dublin longer than Dr. Williams thought, for it had been in use in the City of Dublin Hospital for many years, with very good results. In fact, the question of physical rest which Dr. Williams had alluded to, was one that he (Dr. Finny) thought could be very much enlarged upon not only in relation to the treatment of pleurisy, but of several other affections. There was one question that he thought they should be clear about, and that was —If the existence of pus be recognised, whether the right practice was to tap it frequently or to give free vent to the pus at once? He had some experience of tapping in empyema, and he thought the proper course was to open at once and give free exit to the pus.

The PRESIDENT said he had seen in his time many cases of pleurisy, with effusion, and he had tapped, perhaps, an unusually large number of them—over twenty-five cases—and he thought he might say, as a general rule, with great success. He had tried strapping the chest in many cases, and those in which he thought it afforded most singular relief were secondary cases—cases which arose secondary to phthisis. On the contrary, in those cases of acute pleurisy which would run on to empyema, he thought strapping was not applicable at all, but it gave, he thought, great pain. Many of those cases were accompanied by great external inflammation, as well as internal inflammation—there was external periostitis in those cases which would not bear pressure. Another point of great interest which Dr. Williams's paper rather elucidated was what he (the President) had more than once seen, and that was where a case of well-marked empyema was supposed to have terminated by a fistula, and that the purulent matter which had been secreted was a consequence of the fistula having formed. He had seen several cases where the physical signs gave no evidence of the formation of fistula, but the relief was so great that it was supposed to have occurred, and that relief had taken place over and over again, and the consequence was

that it became a case of chronic empyema, which was more or less accompanied, if the patient survived, with falling in of the chest. With reference to the advisability or otherwise of completely emptying the pleura in cases of great effusion, some time ago it was a very great question as to whether that should be done or the fluid removed in small quantities. There was no question that they were, as Dr. Williams had said, formerly too much influenced by the dread of allowing air to pass into the cavity of the pleura, and that dread was formerly carried to such an extent that all sorts of means were used to prevent the passage of air through the wound into the pleura, while means were taken to completely evacuate the contents of the pleura.

Dr. Williams, in reply, thanked the members for the kind way in which they had listened to the paper, and for the remarks which they had made upon it. In none of the cases that he had as yet strapped for pleurisy had they been, so far as he was aware, connected with phthisis. They had all been, he believed, simply cases of pleurisy—primary inflammatory affection. He had, however, strapped for phthisis. As regarded opinion, he would only say that all physicians had their own opinions about medicines. In his first case he believed it was a great mistake not to make a large wound in the first instance. He agreed with Dr. Kennedy in the belief that the smell of the fluid depended upon the constitutional state at the time. He was not aware that strapping was done in Dublin until the statement which Dr. Finny had made, and was glad to hear its adoption had been so successful. These cases were continually being mistaken for phthisis. He had not found bad effects result from the washing-out of the pleura.

The Society then adjourned.

THE LAW IN REGARD TO UNQUALIFIED PRACTICE—ALLEGED MANSLAUGHTER.

At the Exeter Assizes, before Sir James Fitzjames Stevens, Q.C., Commissioner-Judge, Charles Hornsey was indicted for the manslaughter of Rhoda Burge.

Deceased, for some time before her death, had been suffering from bad legs. The prisoner said that he had no doubt that he could cure them, adding that he had "done great cures." Next day the woman's husband observed that his wife's legs were in blisters. The woman got so ill the day before she died that her husband called in two doctors, and they said they could not save her. On the morning of August 18 (when she died), and about twelve hours before her death, he asked the prisoner how it was he came to make such a mistake. The prisoner asked, "What mistake?" and witness said, "You have killed my wife and ruined me." Prisoner replied, "Oh, Mr. Burge, I have practised this for thirty years and never known anything go wrong." The prisoner then administered an injection in his presence. His wife had a very delicate constitution and suffered from ulcerated legs.

Cross-examined: The prisoner was very kind and attentive to his wife, and the people in the district had every confidence in him.

Mary Corner, widow, residing at Bampton, said she was at work at the house of the deceased, and on July 31 she saw that her legs were in a complete bladder. The prisoner "let" the bladders, and said she was poisoned all over, and that the poison had gone through her whole system.

Cross-examined: The prisoner said to the deceased, "You have taken some poisonous medicine."

Ann Paviour, also a widow, of Bampton, deposed to seeing the prisoner apply a lotion to the legs of the deceased, and handing over samples of it to the sergeant of police.

Dr. Attwater said he was sent for to see the deceased. He found her in a dying state and past human skill. He made a *post-mortem* examination. The brain was in an advanced state of decomposition, the lungs were congested, but otherwise healthy, and there was no trace of any organic disease. The appearances which he saw and described at length, led him to form an opinion that death was caused by the use, in some shape or form, of an irritant poison.

By his Lordship: In no case and under no circumstances would it be proper to apply corrosive sublimate either in the form of lotion or ointment to ulcerated legs.

The only additional evidence was that of Dr. Blythe, who would say that the lotion contained a small admixture of corrosive sublimate.

Addressing the jury, his Lordship said he did not think it safe to leave this case to them, and it was important that they should know why he took the course he now did, and that the law on this subject should be publicly known. The charge against the prisoner, who was not a regular practitioner, was that he had committed the offence of manslaughter. Manslaughter meant causing death either by an unlawful act or by unlawfully omitting to do that which it was a person's legal duty to do. When a man undertook to treat disease it was his legal duty to employ, in the treatment of that disease, a common amount of professional knowledge and skill, and if he failed to employ that, and the result of the failure was to cause the death of the person treated, then he was guilty of manslaughter. He might add that in all cases the prosecution had to show the absence on the part of the accused person of that common knowledge and skill, or, in other words, he had to show gross and culpable negligence or ignorance, and the law applied just the same whether the person who was charged with causing death was a regular practitioner or wholly unqualified. A man might make great professional mistakes, attended with the most lamentable results, even causing death, and yet not be guilty of manslaughter, just as a lawyer might make a great mistake in his practice, and might ruin his clients without making himself liable for negligence. When doing difficult and delicate things, the most skilful man might make a mistake, an error of judgment, and if he did so he suffered in reputation and in other ways, but he was not criminally and not always even civilly responsible for what he did; and in order to make a man criminally responsible, grossly culpable negligence, and ignorance of the common rudiments of professional knowledge must be shown. In this case the other witness who could be called would prove nothing more than this—that the lotion which the prisoner supplied was found to contain corrosive sublimate, and that a small portion of it was found in the woman's liver. They would then have to depend on the evidence of Dr. Attwater, and before they could convict the prisoner it would be necessary to show two things—first, that what he did caused the woman's death; and secondly, that what he did showed such a degree of ignorance as to make it culpable. The evidence that the woman actually died from this corrosive sublimate, and that she did not die from some of the other complaints from which she suffered, was very far indeed from being proved. He had done his best to explain the law on this important subject, and he would now tell the jury that he did not think they could safely convict the prisoner of manslaughter on the evidence given to them, and therefore they ought to find a verdict of "Not guilty."

The prisoner was thereupon discharged.

Translations.

THE USE OF OPIUM IN CEREBRAL ANÆMIA AND AFFECTIONS OF THE HEART.

M. Huchard has pointed out in the *Journal de Thérapeutique*, the good results obtained by the administration of opium, in patients suffering from insufficiency, or aortic obstruction. In the course of certain affections of the heart, when the attacks of suffocation and dyspnœa have acquired an extreme intensity, injections of morphia are of the greatest service.

To support this view, M. Huchard, besides his own personal observations, quotes the facts published by Levy, of Vienna, 1867, by Renauld, in 1874, and by Vibert, in 1875. The communication of M. Huchard presents two points deserving of attention:

1st. The popularisation of the employment of opium in affections of the heart.

2nd. The theory by which the good results are explained.

M. Huchard recognises that other medical men have prescribed morphia in affections of the heart, but his desire has been to fix the indications and contra-indications of the method.

It has been known for a long time that opium in doses

of from one to two centigrammes, amongst other physiological effects, produces slight excitement of the circulation, exhilaration of the spirits, animation of the face, and an increase of muscular power; but if, after the appearance of well-marked phenomena of excitement, the dose be increased from 5 to 10 centigrammes, depression of the circulation and tendency to sleep supervene. Professor Gubler, in his *Commentaries*, insists on the utility of opium in want of stimulation of the nerve centres, due to impoverished or altered blood; and Dr. Vibert, at the end of a Memoir published in the *Journal de Thérapeutique*, 1876, concludes that the previous employment of injections of morphia in the operation of thoracentesis, and even in all operations giving rise to syncope, prevents the occurrence of such accidents. M. Huchard employs opium in the hope of utilising its hyperæmiant properties on the nerve centres, and particularly on the brain. In patients suffering from aortic obstruction, or insufficiency, with symptoms of suffocation, dyspnœa, cold sweats, pallor of the face, &c., he has seen these formidable symptoms disappear after the injection of one centigramme of morphia.

If opium be useful in cases of aortic affection accompanied by vertigo, buzzing in the ears, tendency to giddiness, cephalalgia, it is because such symptoms are those of cerebral anæmia, and that cerebral ischemia is a frequent complication, not only of aortic insufficiency, but of aortic lesions in general. Hence the administration of opium is indicated in the course of affections in which cerebral ischemia is equally met with.

In M. Huchard's opinion, as in that of Professor Gubler, opium may be used in certain forms of anæmia, as it acts as an excellent tonic owing to its congestive action on the brain. It may be prescribed for cachectic or phthisical patients, for in such cases, besides the tonic action of opium recognised by Sydenham, we also utilise the power of this medicine to calm the dyspnœa and the cough.

T. M. Dolan.

THE MEDICAL REFORM COMMITTEE AND THE MEDICAL COUNCIL.

Towards the close of the late session of the Medical Council, several of its members assembled at an early hour to meet a deputation from the Medical Reform Committee. The members present were Dr. Acland (President), Sir James Paget, Sir Dominic Corrigan, Mr. Macnamara, Mr. Teale, and Drs. Rolleston, Pyle, Storrar, Apjohn, Andrew Wood, and Quain. The deputation consisted of Dr. Waters of Chester, Dr. Davey of Bristol, Dr. Wade of Birmingham, Dr. Stewart of London, Dr. Leech of Manchester, Mr. Wheelhouse of Leeds, and Mr. Nicholson of Hull.

We quite sympathise with the object which the Reform Committee has in view, and will admit that although its representative status has been impugned, it does, with regard to certain important questions of medical reform, really represent the opinion of the great body of general practitioners. The deputation, however, like most deputations, led to no result, and was little more than a matter of form on the part of the Reform Committee, and of curiosity on the part of the Medical Council. Nor could anything else have been expected. As the President remarked, the Council had been called for a special purpose, namely, to consider the Duke of Richmond's Bill, and it could scarcely be supposed that the Council would have time to take into consideration such an important subject as that of completely altering its own constitution. Consequently there was from the first very little hopes of the movement represented by the Reform Committee receiving much attention, much less encouragement, from the Council. On the contrary, the reception of the deputation appears to have been marked by an air of austerity and self-satisfaction which could scarcely have escaped the observation of the several members composing the deputation, and which might almost warrant the thanks which Dr. Waters returned to the President and the Council "for their kind attention" being taken in a rather ironical sense. The self-satisfaction of the Council with regard to its catholicity as a representative body, was well illustrated by the remarks of Drs. Acland and Storrar. The latter regarded himself as representing not only the profession, but the intelligent public at large. The President stated that the Medical Council had done its best for the profession, and he should like to know what member of the Council would say he did not represent the profession. It must not for one moment be assumed that the motive of those who had seats at that table was simply and solely to represent the interests of particular institutions. Such remarks, however, are little more than an evasion of the question at issue. In theory, and indirectly, each member of the Council may be said to represent the profession, but practically, and directly, the great body of medical practitioners has no representative on the Council. As Sir Dominic Corrigan very ingenuously admitted, the Council merely represents the corporations, the Universities, and the Crown. It is, we admit, only natural that each member of a representative council should consult the interests of that body or corporation by which he has been elected, and of which he is the chosen delegate. No doubt the motive of those who have seats at such a council is not "simply and solely" to represent the interests of particular institutions, but it is impossible for such members to keep their minds quite unbiassed and free from all prejudice in favour of those institutions. Will anyone venture to say

that those Scotch and Irish members who voted *en masse* against the Conjoint Scheme, simply and solely represented the interests of the profession and the public? We cannot, for reasons just stated, wholly blame them for the predilections which they showed on that occasion, but the fact that such predilections were shared by a large minority of the Council—a minority wholly composed of the delegates from the Scotch and Irish corporations—shows, as we have before observed, that the Council should be partly composed of members who are prejudiced in favour, not of this or that corporation, but of the public and the profession at large, for whose benefit the General Medical Council was originally constituted.

Nor did the questions put by the Council to the deputation show that the former would very readily recommend to the higher authorities the propriety of its own self-reconstruction. Did the Medical Reform Committee represent the general body of the profession? Had "Dr. Waters and his party" considered the difficulties that would lie in the way of a direct representation of the whole profession? Had a calculation been made of the expenses of such an election as that contemplated by the Committee? Would not the compulsory clauses for a conjoint examination have been passed in Lord Ripon's Bill if the Committee had not interfered to prevent it? Did the Committee claim direct representation as a right, or with the idea that it would improve the Medical Council? Such were the kind of questions which the Council put to Dr. Waters, the general tone of which clearly indicated that the Council was not very sanguine as to the necessity or practicability of its reconstruction. There can, however, be no doubt that the time will come when the proposed reconstruction of the Council will be an accomplished fact; but it is evident that the attainment of such a desirable object can only be secured by the united efforts of all those who are anxious that the Council should represent more perfectly than it does at present the general body of medical practitioners, and who object to its acts being so much influenced, or its opinions divided, by the prejudices of men to whom vested interests are more dear than the interests of the public and the profession.

THE FICTION OF SMALL DOSES.

No one acquainted with the recent literature of therapeutics can have failed to notice that many medical practitioners have got into the habit of prescribing certain medicines in very small doses. For years this has been the habit of those who are given to write long and elaborate prescriptions, the ingredients of which have probably as much effect upon the disease for which they are prescribed as so much simple water. Two or three drops of tincture of hyoscyanus, four or five of ipecacuanha, ten or fifteen minims of the compound tincture of camphor—one fluid drachm of which contains but a quarter of a grain of opium—five or ten minims of the aromatic spirits of ammonia, of the spirits of chloroform, or of ether—these are the doses we have constantly seen prescribed for adult patients, whose symptoms were of so severe a nature as to call for more heroic remedies. In fact, herein lies one of the improprieties of writing long prescriptions, for then not only is it impossible to say to which drug the relief or recovery of the patient is due, but the practice engenders the habit of prescribing a lot of "adjuvants" in such small doses that they are in nine cases out of ten quite inert. Indeed, we feel ashamed to contemplate the incalculable waste of medicine, and the downright self-delusion, which are the outcome of the reckless and theoretical manner in which so many of us are apt to "make up" a mixture or write a prescription. No doubt all this is good for trade; the chemist reaps a handsome profit by it; the physician may or may not be labouring under a slight delusion; and if no good, at least no harm, is done to the patient. It is, however, but a sorry reflection upon the practice of medicine, and promises little for the advancement of therapeutics by individual observation. But in many instances medicines are ordered in very small doses from principle, and from a belief that their efficacy is thereby increased, or is as great as if they were administered in larger quantities. For example, Dr. Sydney Ringer, whose work on therapeutics is so well known, states that, according to his experience, one drop of ipecacuanha, repeated every hour, will arrest some forms of vomiting; and not long ago an American physician espoused in the pages of the New York *Medical Record* the doctrine of small doses. He said that his investigations had been carefully made, and had extended over a long period of time. The scheme was tried in private and hospital practice, and the result appeared to him sufficiently satisfactory to induce him to deliver before a medical society a forcible address, in which he declared his opinion in favour of small doses.

If, however, we reflect for one moment upon the principles of allopathic medicine, and the universal experience of allopathic physicians, we can come to no other conclusion than that the administration of drugs in very small doses is, as a rule, wrong, both in theory and in practice, and that the supposed efficacy of that plan of treatment is nothing less than a delusion. We can see some sense in the homœopathist giving his drugs in small doses, for were it a natural law that any symptom of disease may be relieved or removed by a drug capable of producing the same symptom in a state of health, it might also be a natural law that the drug, to be efficacious, should be given in comparatively minute quantities. At all events, there is something plausible in the principle upon which a homœopathic dose of medicine is exhibited. But we are certainly at a loss to understand on what grounds a practitioner of rational medicine can defend that practice. If medicines were classified according to the principles on which they are prescribed—a classification which is not so often adopted as it should be—we should find that most of them are given with the view of increasing or diminishing the activity of some great function of the body, while others are given with the view of making some impression upon the nervous system, or of supplying some deficieney, or correcting some fault, in the composition of the blood. We need not at present enter into the reasons why these intentions are kept in view by the allopathic physician; but that all our medicines are in nine cases out of ten given with those intentions, is evident to every one who is in the habit of prescribing diaphoretics to increase the action of the skin, diuretics to increase the action of the kidneys, purgatives to in-

crease the action of the bowels, ferruginous tonics and lemon juice to improve the quality of the blood, quinine and other nervine tonics to make an impression upon the nervous system. But the universal experience of the profession testifies to the fact that if any medicine belonging to the above classes of drugs be given in doses short of the minimum dose specified in the Pharmacopœia, it will most surely fail in producing the desired effect. In all those cases in which the therapeutic efficacy of certain drugs cannot be questioned by anyone, however sceptical he may be, or to whatever medical persuasion he may belong, the largeness of the dose seems to be an important factor in its therapeutic action on the system, and the influence it has upon the disease for which it is prescribed. Hence the unquestionable efficacy of large doses of iodide of potassium in secondary syphilis; of large doses of quinine in arresting the progress of intermittent fever; of comparatively large doses of mercury, in some form or other, in the treatment of syphilitic iritis, and certain syphilitic affections of the skin; of large doses of bromide of potassium in some cases of epilepsy; of comparatively large and long-continued doses of arsenic in certain skin diseases; and of large doses of the hydrated peroxide of iron in the treatment of certain neuralgias. It is the same with other and less potent remedies. Large and frequently repeated doses of the liquor ammoniæ acetatis, or a full dose of Dover's powder, will act upon the skin and excite diaphoresis, when a grain or two of the one, or a few drops of the other, would have no effect whatever. Give a small dose of morphia to a patient in the agonies of a severe attack of colic, or in a paroxysm of mania, and you might as well try to soothe him with the mesmeric pass. Administer a mild aperient to a man suffering from constipation and biliary obstruction, and ten to one you will rather aggravate than remove his complaint.

Nor should it be forgotten that in handling the more powerful and poisonous drugs, the practitioner often fails in obtaining the wished-for result, because, through fear of giving them in too large doses, he errs on the other side, and prescribes them in such small quantities as to render them practically inert. This is very apt to be the case in prescribing certain narcotics and sedatives, such as opium, henbane, prussic acid, the lobelia inflata, &c.

Dr. Sydney Ringer thinks that the medicine last mentioned would be found far more efficacious in the treatment of asthma than it usually is, were it given in large doses. Hydrocyanic acid often had, in the hands of Drs. Elliotson and Pereira, a magical effect in the treatment of severe attacks of gastrodynia, but these physicians gave that medicine in much larger doses than practitioners are now in the habit of prescribing it.

From the foregoing observations it follows that by prescribing medicines in too small and ineffectual doses, we not only fail to fulfil the intention for which we prescribed them, but we lose confidence, and lead other practitioners to lose confidence, in the virtues of the drug. Indeed, many a remedy has been cast aside as being of little or no value through its having been prescribed in too small quantities to enable the practitioner to give it a fair trial. In prescribing medicine, it should be a rule not to give more than one or two drugs at the same time, but to prescribe them in such doses that in the event of their not having the desired result, we can be certain that the failure did not arise from our not having given enough of them.

Notes on Current Topics.

General Paralysis in Syphilitic Patients.

Our readers have probably been much interested in the series of articles from the pen of Dr. Stretch-Dowse, which have been appearing in our columns during the past few months. M. Fournier, an eminent French authority, thus sums up his views:—

Undoubtedly, general paralysis does occur in syphilitic subjects sometimes, but *sometimes* only, and in quite too exceptional a manner to warrant our regarding it as depending directly upon the evolution of the syphilitic morbid processes. It is reasonable to suppose that a disease which affects the nervous system so profoundly as does syphilis, may be the determining cause in some cases. In syphilis itself the mental disturbances are not quite those of general paralysis; they may, indeed, present all varieties of excitement, violence, depression, or dementia, but they do not follow any special type, as do those of general paralysis. The condition of self-satisfaction of the unfortunate subjects of general paralysis, who imagine themselves kings, prophets, great artists, who revel in fancied wealth, and propose every day fresh schemes, magnificent in the extravagance and boundlessness of their scope, all that makes up the common description of their delirium, is absent, or at least only exceptionally present in syphilis, and when present, the extravagance is tame and humble in comparison. Tremor may be present in syphilis, but is only occasional; that of the tongue especially is very rare, while the tremor of the upper lip, so frequent in general paralysis, is perhaps never present—at least, M. Fournier has never seen it. Above all, the tremor lacks the constant, fibrillary, vermicular character of that of general paralysis. These differences are not merely of degree, but definite, and more easily recognised clinically than described by words. Paralysis and paresis of all kinds are common in syphilis, and correspond to what is ordinarily understood by those terms; whereas in general paralysis it is more a want of co-ordination and defect of precision, than abolition of muscular power. Again, in syphilis there is excessive frequency of partial paralysis affecting a special predilection for certain parts; for example, the muscles of the eyeball, a peculiarity which is not found in general paralysis. Hemiplegia, transient or permanent, is often one of the earliest phenomena of cerebral syphilis, and of great frequency in some period of the disease. Finally, in syphilis, motor phenomena, apoplectic attacks, &c., commence the affection; in general paralysis, intellectual and moral disturbances prelude the symptoms of cerebral disorganisation, while similar distinctions mark the course of the two diseases, syphilis being irregular, variable in its progress, in the succession of phenomena, and its duration; general paralysis, on the other hand, is regular, and of definite duration. The comparison of the general state of the patients in the two diseases gives not less

striking distinctions—in syphilis, cachexia; in general paralysis, maintenance of nutrition, even *embonoint* up to the very last. Finally, syphilis may be regarded as at least possibly curable, gloomy as is the result in most cases, yet differing even in this from the other absolutely incurable malady.

Chorea in Old People.

Prof. Charcot thinks chorea in old people does not differ much from the ordinary chorea of Sydenham. Its rarity is remarkable; at present he has under treatment two cases *Alten and Cour*, and only three have been recorded by Graves, Sée, and Roger. It does not seem modified when transplanted to the aged, at least, essentially, except perhaps in the relative slowness of the movements and its very chronic course. One of his patients had suffered from it eleven years, the other twelve.

As regards prognosis, it is incurable, though it does not seem to endanger life. He had, however, seen one patient die in a typhoid state with a considerable elevation of temperature, whilst another case terminated in maniacal delirium with elevated temperature. Most of the patients affected with chorea have appeared to M. Charcot to be in a state of more or less pronounced dementia. Its etiology differs a little from that of children; it does not in the aged seem allied to rheumatism. No cardiac lesions were found at autopsies. In the aged it appears an emotional disease.

In Cour, chorea supervened, "after circumstances, about which," said the patient, "I cannot speak without shedding tears." In Alten, chorea resulted after the following occurrence: Her husband, of unsound mind, was for many years an inmate of the Bicêtre, and she was in the habit of visiting him weekly. One Sunday, on arriving at the hospital, she found he had been transferred to the Province; she was so disappointed that chorea supervened some days afterwards.

Recently, M. Charcot observed a case of chorea in an aged man. It had developed first in the upper members, subsequently becoming general. During two years the tremor was so violent that sleep was impossible. Bromide of potassium had been tried in large doses with but trifling abatement of the symptoms. Common chorea in old persons should not be confounded with another pathological condition designated under the name of "senile chorea," and which is only senile trembling. M. Charcot has often met with patients attacked with the latter disease, the difference between which and common chorea is pointed out in a lecture published in *Le Progrès Médical*, 1876, p. 815.

The St. John Ambulance Association.

The *Standard* newspaper has recently given a very good account of the object and work of this excellent association. It was founded, and is now in course of organisation, by the Chapter of the Order of St. John of Jerusalem in England, for the instruction of individuals in the method of tending and relieving persons injured by such accidents as are of daily occurrence in civil life in time of peace, and for the formation of a body of hospital helpers trained on the official military system of drill, and available as a reserve to the Army Medical Department, should this country be unfortunately engaged in war. It was, we believe, in 1869 that such a work was first contemplated in England, and a small group of men would undoubtedly have then succeeded in establishing it, had they not been interrupted by the outbreak of the Franco-German war. The Association makes work in time of peace of supreme importance, but one important feature in its programme is the preparation to be made in time of war. Another characteristic of the Association is that the whole initiative belongs to private individuals, whereas in Germany and Russia the same work is fostered and assisted by Government. The organisation, as far as it actually extends, is in the hands of a central Committee in London, composed exclusively of members of the Order of St. John; and the principal duties of this body consist in keeping all the different town and provincial centres *en rapport*, whilst allowing to each as much freedom in framing and carrying out their own regulations as is compatible with necessary system and cohesion. The registers and reserves of money and material are also concentrated and administered at head-quarters.

The principal local centre yet established is at Woolwich, and here, as well as at Chelsea and Sevenoaks, classes for men and women are held weekly. A most successful class for men is just completing its course at the Custom House; whilst at Paddington there is an equally enthusiastic and well-conducted class for ladies. Maidstone, Brighton, Worcester, and other towns or places will soon follow, or have already followed in the same direction; and at Brighton twenty-five ladies have entered their names for instruction. The instruction is given by members of the medical staff in a popular and practical manner, and with that zeal and disinterested devotion which is so conspicuous a characteristic of their professsion. At the termination of each course of lectures, which is dependent on the instructors, there is an examination, attendance at which is quite optional on the part of the pupils. Those who can pass to the satisfaction of the examiners receive a certificate to the effect that they are qualified to afford first assistance to persons injured by accident or otherwise. Not only has the St. John Ambulance Association a considerable guarantee fund ready for the outbreak of any war in which the British military forces may be engaged, and a steam yacht kindly placed at its disposal by the Marquis of Conyngham for the conveyance of its *personnel* and *matériel*, but the roll of the society already includes the names of 127 persons qualified as physicians, surgeons, dressers, storekeepers, dispensers, nurses, and bearers, of whom 72 are willing to take service abroad, as a supplement, if necessary, to the Army Medical Department. The Association already possesses a few ambulance carriages of the best and and newest patterns, and the excellent two-wheeled litter patented by the Order of St. John; and a larger number of useful stretchers and other ambulance necessaries are being rapidly distributed throughout the kingdom. Such are the chief objects of the Ambulance Association, and we need scarcely remark that it will receive from the medical profession, especially from our hospital authorities, all the encouragement and support it deserves. There is every indication that its services will before long be taxed to the very utmost, and it is to be

hoped that the public will help in the good cause by supplying funds without which the work of such an Association cannot be satisfactorily or largely developed.

Unqualified Assistants in England.

At the recent meeting of the General Medical Council, Sir Dominic Corrigan moved—

"That while the Council cannot undertake the duty of prosecuting unqualified practitioners, they nevertheless think it their duty to draw the attention of the Local Government Board of England to a practice, which it would appear exists in England, of practitioners in charge of medical relief districts employing unqualified assistants to act for them in the treatment of medical and midwifery cases, tending to the detriment of the public and other evils; and they would suggest to the Local Government Board of England the consideration of the rule in Ireland, that no medical officer in charge of any dispensary district is permitted to have a substitute to perform his duties unless for a limited time, and unless such substitute is fully qualified to the satisfaction of the Dispensary Board, and with the sanction of the Local Government Board."

The *Lancet* referring to the subject, says, "Sir Dominc is to be praised for raising this question, but, as we understand the matter, the rule is very much the same in England as in Ireland. The medical officer is bound, as far as practicable, to do the duty himself, and, where he cannot to find a substitute. An assistant may act as a substitute but he must have at least one qualification and be registered." Our contemporary is certainly misinformed as to the practice in Ireland. In England we believe that a poor-law medical officer cannot legally delegate his duties to any but a qualified person, but, as a matter of fact, a great part of the medical attendance on paupers is performed by unqualified persons, the medical officer being responsible, and nominally discharging the duty himself.

In Ireland a medical officer has no power to delegate his duty to anyone, or to name a substitute. No assistant or other person, qualified or unqualified, saving the medical officer himself, is allowed to touch a dispensary patient, and when the medical officer becomes sick, the substitute is appointed by the Dispensary Committee, and is neither controlled nor paid by the medical officer.

The Small-pox in Dublin.

According to the Registrar-General's latest returns, the deaths from small-pox for the week ending April 20 were six less in number (9) than those of the previous week (15). Notwithstanding the apparent improvement in the epidemic, the number of cases in hospital (203) shows an increase of 34 upon the number of the previous week.

The quarterly returns for the three months ending March 30 tell a miserable tale of sickness and sanitary incompetence. The death-rate for that term was 31·3 per 1,000 of the population, while that for London was only 25·5, for Glasgow, 26·3, and for Edinburgh 26·8 per 1,000.

Irish Centenarians.

The death of a veritable centenarian is reported by Dr. Crosslee, of Newry. Mrs. M'Camley, the deceased, was born on the 4th of October, 1775. It will thus be seen that the deceased lady had reached the ripe old age of exactly 102 years and 28 weeks. Her last surviving brother died at Newry, in the year 1849, aged 80 years. Her father died at the advanced age of 86 years; and her paternal uncle, and grandfather of the present Dr. May, of Rathfriland, died suddenly, being at the time of his death 100 years of age, and in the possession of excellent health and unimpaired faculties. Mrs. M'Camley herself, although confined to the house for the past two years, was, up till within five days of her death, in fairly good health.

Dr. Crosslee mentions that, during the last six months, he registered the deaths of eighteen persons resident in his district, whose united ages amount to 1,371 years, making an average age of 76 years for each individual.

Prosecutions against Offenders against the Irish Pharmacy Act.

At the last meeting of the Council of the Irish Pharmaceutical Society, Mr. Holmes moved—

"That the time has arrived for the Council of the Pharmaceutical Society to protect the Licentiates of the Society from infringements of their rights, and that a Committee be appointed to consider the best means of so doing."

Sir G. Owens seconded the motion. The motion caused a lengthened discussion, and was strongly opposed by the medical element in the Council. A division was taken with the following result:—For, 8; against, 5.

The Employment of Dialysed Iron.

The profession in America has taken up this preparation with its accustomed zeal, and many valuable results are chronicled in our exchanges.

Professor Da Costa has employed it in a case of chlorosis, in a woman aged twenty-one years. The patient had daily injections of 15 minims of the iron solution, at first diluted, but afterwards of full strength. The points where the injections were made showed no evidence of inflammatory action. Subsequently the dose was raised to 30 minims, and convalescence was rapid. After the hypodermic use was discontinued, 20 drops in water were given thrice daily for a short time. No constipation, indigestion, or other disturbances resulted from this mode of using the remedy, and recovery was considered to have been more rapid than it would have been with the usual way of administering it.

In Canada also its use seems to have met with signal success, where Dr. Hayes treated a case of arsenical poisoning with dialysed iron. Following an emetic and free draughts of warm water, a tablespoonful of the dialysed iron was given and soon ejected; doses of thirty drops were then given every twenty minutes for two hours. Two hours after his arrival, symptoms of collapse set in, and were treated with brandy, hot bottles, and friction. The patient was restored to health in about ten days, and complained during convalescence of weakness, thirst, and a burning sensation in the stomach. Dr. Hayes estimates that fully a teaspoonful of arsenious acid was lying in the stomach from half-a-hour to an hour before he saw her.

The Purification of Water.

On Thursday last, Professor Bischof, best known for his discovery of spongy iron for the purification of waters, and of the most perfect filter extant, read a paper before the Society of Arts, before a large audience, on this interesting subject. The author stated that absolutely pure

water containing exclusively oxygen and hydrogen in the proportion in which they chemically combined to form water, was unknown even in the laboratories of chemists. The foreign matter in water was either gaseous, mineral, or organic. The gases which usually occurred in water, viz., free oxygen, nitrogen, and carbonic anhydrite, were, in moderate quantities, not only harmless, but even desirable. It was observed that shallow well and river water was generally most largely polluted. At ordinary times there was no actual danger in drinking almost throughout the year the water supplied from the Thames to the greater part of London, if it was sufficiently filtered through sand. But now and then, especially in times of flood, the water deteriorated, sometimes very seriously, and therefore there ought to be at least some additional means beyond those at present employed of purifying Thames water during certain periods of the year and during the prevalence of epidemics. Animal charcoal and spongy iron were recommended as efficient chemical purifiers. The use of sponges was condemned as being hotbeds for collecting the lower forms of organic life. Fresh animal charcoal removed not only a large proportion of the organic impurity, but also of the mineral matter; but it required to be frequently changed—in the case of Thames water every three months.

Vaccino-Maniac Martyrs.

Mr. Nye, a watchmaker of Chatham, who has undergone six or seven terms of imprisonment in Maidstone Gaol for refusing to have his children vaccinated, and whose case was brought before the House of Commons a short time ago, was on Monday taken to Maidstone Gaol again to undergo another month's imprisonment for a similar offence, and for refusing to pay the fine imposed. Mr. Nye is secretary to the Anti-vaccination Society. However much we may regret that a fanatic is to be found willing to undergo seven successive terms of imprisonment, for, let us assume, conscience sake, and however astonished we may be that an Englishman can be found so unwilling to listen to, or incapable of appreciating reason and fact, we cannot by any stretch of charity towards the foibles of our neighbours, admit that any person has a right to set his own views against the law of the land.

It is unhappy that the conscientious convictions of any person should clash with those of the community, but if they do so, *tant pis* for the victim of those convictions. One does not inquire whether or not a Fenian is conscientiously an assassin, or whether a thief has peculiar views as to ownership.

Another Homœopathic Recantation.

A correspondent of the *New York Hospital Gazette* asks, "did mortal ever behold a more miserable spectacle than that presented by the Homœopathic Medical Society of this country at its last meeting, March 11, when the question propounded was—Shall we continue under the appellation of Homœopathists, or, in obedience to more modern teachings, and in the lurid light of allopathic (so termed) scientific advancement, *must we* renounce the delusive principle of our fathers, *similia similibus curantur?* We must obey the mandates of truth, was the decision of a vote of 18 to 17; and thus descends to the grave the last relic of this vicious system of practice."

Irish Pharmaceutical Society—Resignation of Sir Dominic Corrigan.

At the last meeting of the Society, a letter from the President was read, signifying his intention to resign his position. Several members strongly urged the President to withdraw the letter, and the Council would willingly excuse his attendance when not convenient for him to be present. Sir Dominic said he thought that the time had arrived for the Society to conduct its affairs without external aid, and spoke in warm terms of the kindness he had always met with from each individual member of the board. He considered his being selected by Government as the first President of the Society was the highest honour he had ever been favoured with. No decisive action was taken in the matter, but it is generally believed that the resignation will not be withdrawn.

A Penny Hospital Fund.

Three years ago, when the Hospital Saturday Fund was mooted in London, we ventured a suggestion, that the majority of working men when in employment, would, if asked, contribute towards the hospitals out of their weekly earnings, and thus constitute at the end of each year a splendid fund for distribution. The medical profession has an inherent dislike to display, and the Hospital Saturday Fund, with its ostentatious street show, has never been popular in consequence. We are delighted, therefore, to hear that there is at last a prospect of our suggestion being carried out. The idea is to collect a voluntary offering of a penny per week from each man, the employer, or some trustworthy authority of the establishment, to be treasurer during the year, or portion of year set apart for this purpose. If this can be carried out, a valuable addition to our hospitals will be the result, the men themselves will not miss the amount subscribed, and they will have gone far to redeem the opprobrium often cast at them for not supporting the institutions specially designed for their benefit.

The Vacant Superintendentship at Bethlem Hospital.

We understand that Dr. Rhys Williams, Medical Superintendent of Bethlem Royal Hospital for Lunatics, has been appointed by Her Majesty's Government a Chancery Commissioner in Lunacy; in consequence of which a valuable post is placed at the disposal of the Governors of that Institution. The salary is £700 per annum, exclusive of pupils' fees, with furnished residence, coals, gas, &c. No names are yet announced as candidates, the vacancy having been known but a few hours. It is, however, highly probable that Dr. Savage, who has every qualification for the post, and has, moreover, undergone a thorough initiation as assistant medical officer for some years past, will be elected, should he offer himself as successor to Dr. Williams, in which case a vacancy in the assistancy will be created by his elevation.

Telegraph Workers' Disease.

At the last meeting of the Biological Society of Paris, Professor Onimus brought under the notice of the members, an affection which he calls "Mal Télégraphique" due, not only to the fatigue of certain muscles, but to the constant tension of the mind involved in telegraphic work. Besides the local symptoms there are general phenomena, as palpitation, vertigo, insomnia, and cerebral disturbance. People of nervous temperament seem to be especially liable to attacks.

The Old Question—Drunk or Dying?

This question is so often cropping up that we should take no notice of a case reported a few days ago in the newspapers, were it not that the case shows that even the confession of the supposed drunkard cannot always be depended upon, and will not always settle the question whether he is drunk or dying. In this instance the deceased was knocked down by a hansom cab in Barbican on Saturday night. A policeman found her in an insensible condition, and as she did not appear to have been under the influence of drink, he took her in a cab to St. Bartholomew's Hospital, where, on recovering consciousness, she acknowledged she was drunk. An emetic and other medicine were administered, but they had no effect upon her. After being at the hospital an hour and twenty minutes the policeman was ordered to take her away. He did so. Some time after she was found dead in a cell of the Moor Lane police station. A surgeon who had examined the deceased stated that there was no proof that she had been drinking, and that the cause of death was apoplexy, accelerated by the injuries from being knocked down by a cab. The jury returned a verdict in accordance with the medical testimony, adding an expression of opinion that the woman should have been kept in the hospital, and not sent to a police cell.

We scarcely think that the hospital surgeon was to be so much blamed in the matter as the observations of the jury would imply. The fact of the woman recovering consciousness and confessing she was drunk, was quite enough to put the most experienced physician off his guard. In all probability, too, she had been drinking, the effects of which had, under the circumstances, contributed to produce the disease from which she is said to have died. In a diagnostic point of view, it is rather a rare and instructive case. The fact of her again falling into a comatose state, after having recovered consciousness (if such were really the fact), and the circumstance of her having been knocked down by a cab, might have aroused some suspicion with regard to the true nature of the symptoms. But we say only "might;" *humanum est errare*, and we are not surprised that, looking at all the circumstances of the case, she was ordered to be taken away.

Dr. Richardson on Alcohol.

Dr. Richardson does not seem to get tired of lecturing on one of his favourite subjects, namely, the action of alcohol on the system, and the benefits of total abstinence. This week he lectured at the London Institution, before the Hunterian Society, but he had little more to say on the subject than what the reader is already familiar with. It has been said (and in our opinion with some basis of truth) that practised abstainers were men of melancholy mood; that they lacked vivacity, and wit, and sparkle, that their firesides were cheerless, and all but inhospitable. If, remarked Dr. Richardson, these sayings were true, they would indicate the presence of an unhealthy condition both of body and mind. In fact, they were both open and ignorant falsehoods, offsprings of prejudice and superstition. He knew from direct observation that these statements were untrue. His proposition on the subject of the practice of total abstinence in health would be, that it carried with it every advantage, even by the side of the systematic enjoyment of alcohol. As to the question of the practice of total abstinence in disease, alcohol belonged to him as a physician in the character of a remedy; he had as just a right to it as he had to opium or chloral, if he knew when to use it properly, when he knew its physiological action and its therapeutical application. When he spoke of alcohol in that sense he spoke of it absolutely as a distinctive thing.

We are glad to see that Dr. Richardson does not go the length of some alcoholphobists, and proscribe it even in the treatment of disease. But once admit that alcohol may be administered as a medicine, you then, for reasons we have stated on a former occasion, offer one argument in favour of the occasional and temperate use of it in apparent health. For considering the various conditions and exigencies of modern life, how few there are who can say that they are always in a state of bodily and mental health? But it will be said that in that case it should be used as a drug, and only prescribed by medical advice. To this we answer, are not medicines universally taken by the public independently of medical advice, and will a little light wine taken in moderation do more harm than taking a lot of antibilious pills or some famous patent medicine?

The University of Edinburgh.

The Edinburgh correspondent of the *Times* remarks that the University of that town has this week concluded the most successful session in its history of 296 years with the usual graduation ceremonial. This fact is chiefly owing to the great impetus that the Universities Act of 1858 gave to graduation in arts. Previously to that period the number of graduates rarely exceeded six or seven. But since non-professional were conjoined with professional examiners, and especially since graduates in arts were made members of the General Council of the University, the number of graduates has been steadily increasing; and a farther impulse to graduation was given in 1868, when the Reform Act gave two members of Parliament to the four Scottish Universities. This year the number is 101, and there are already indications of further increase. In the same interval the number of students in the Arts Faculty has grown from 600 to nearly 1,000, and in the whole University from 1,400 to 2,500. No other Scotch University approaches Edinburgh in the matter of numbers. Glasgow stands next, with about 1,800 students. The graduation ceremonial was held in the Assembly Hall, Castle Hill. The most interesting part of the ceremony was the presentation of the honorary graduates, among whom were Professor Stanley Leathes, of King's College,

for the degree of D.D., and Lord Houghton, Mr. F. T. Palgrave, and Mr. Samuel Smiles for that of LL.D. All these gentlemen were well received, but the ovation of the day was reserved for Mr. Smiles.

The West London Hospital.

THE remarks in the leading article which lately appeared in a daily paper respecting the case of Mrs. Baker, appeared to us, at the time, both premature and unjustly severe, and therefore we are glad to see that the chairman of the house committee of this hospital has written to say that the committee has made full inquiry into the case, and finds that Mrs. Baker was not refused admission by the porter. The two porters positively state, and are prepared to swear to that effect. The chairman further states that the porters are not allowed to exercise their discretion, but have strict orders to admit all applicants desirous of seeing the medical officers.

SOME valuable donations and legacies have been received by several of the medical charities during the past few days. The London Hospital, the Metropolitan Free Hospital, and the Jews' Hospital have each received £1,000, under the will of Miss Goodman. The Manchester Royal Infirmary has received £1,000, under the will of Mrs. Foxton, of Pendlebury. Sir Arthur Guinness has given about £900 for furnishing the new Coombe Lying-in Hospital, Dublin. The Misses Brooke have given £500 to the Hospital for Incurables, £100 to the Jervis Street Hospital, and £100 to St. Mark's Hospital, all of Dublin. Mr. Pascal Law has given 800 guineas to the Stewart Institution for Imbeciles.

THE deaths from small-pox in London, which had been 48, 55, and 58 in the three preceding weeks, further rose last week to 80, a higher number than in any week since the end of April, 1877 ; 54 were recorded in the Metropolitan Asylum Hospitals, one in the Highgate Small-pox Hospital, one in an ambulance, and 24 in private dwelling-houses. There were 9 deaths in Dublin from this disease, against 15 the previous week. No other death is reported in any other town.

THE annual rate of mortality, in the principal foreign cities according to the most recent weekly returns, was, in Calcutta 43, Bombay 41, Madras 57 ; Paris 27 ; Geneva 27 ; Brussels 32; Amsterdam 25, Rotterdam 27, The Hague 24; Copenhagen 23 ; Stockholm 33 ; Christiania 25 ; St. Petersburgh 60 ; Berlin 29, Hamburg 29, Dresden 30, Breslau 37, Munich 41; Vienna 37, Buda-Pesth 50; Rome 40, Naples 46, Turin 56, Venice 39 ; Alexandria 34 ; New York 27.

THE fund started some time since for the purpose of erecting a statue to the illustrious Harvey at Folkestone, his native town, is progressing very fairly, though not quite so rapidly with the general public as we could desire. The latest subscriptions include one hundred guineas each from the Royal Colleges of Physicians and Surgeons of London. The total amount now reaches about £1,400. Further contributions are solicited by the Honorary Treasurers.

THE annual rates of mortality last week in the large towns comprised in the second category were—Norwich 18, Salford 18, Leicester 19, Bristol 20, Hull 20, Portsmouth 20, Brighton 21, Nottingham 22, Wolverhampton 22, Leeds 22, Newcastle 22, Sheffield 23, Bradford 24, Birmingham 24, Sunderland 26, Manchester 30, Liverpool 31, Plymouth 34, and the highest rate 38, in Oldham, per 1,000 of the population.

WE regret to announce the deathof Mr. T. Carr Jackson, F.R.C.S., Surgeon to the Great Northern Hospital, and Viee-President of the Harveian Society of London. Mr. Jackson has been ailing since the death of his wife in October, but his death was somewhat unexpected when it occurred last week. Deceased was but 55 years of age.

WE hear that the School Board of London have, on the application of the National Life-boat Institution, decided to instruct all their scholars, now numbering 111,000 children, in the important directions for the restoration of the apparently drowned.

LAST week the mortality was at the average rate of 26 deaths annually in every 1,000 persons living throughout the kingdom. The annual death-rate was 26 per 1,000 in London, 27 in Edinburgh, 29 in Glasgow, and 30 in Dublin.

FOR the first time in Holland, the degree of Doctor of Medicine has been conferred upon a lady, Miss Aletta Jacobs, who has announced her intention to practice in medicine at Amsterdam.

Correspondence.

THE TITLE OF "DOCTOR."

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I observe that the editor of the *British Medical Journal* speaks of it as a "grievance" that "the great proportion of English medical men are debarred from the use of the title of 'Doctor,'" and he infers that the chance offered by the Duke of Richmond's Bill should be availed of to place that title at the disposal of all licensed practitioners. I beg permission to remind such practitioners that it is already entirely open to them if they are prepared to gain it by the requisite study ; and I certainly do not regard it as any "grievance" that a person who declines the trouble, delay, and expense of winning such a decoration should be denied the right to wear it. I perfectly understand the complaint that licentiates of Durham, St. Andrew's, and the Queen's University are permitted to call themselves M.D., while those of other Colleges—quite as deserving of the title—are not so permitted ; but I altogether deprecate the remedy for the anomaly by levelling down ; and I maintain that, on the contrary, the Duke of Richmond should level up by means of an enactment that no person should be granted a Doctorate in Medicine until he had previously taken a full degree in Arts. You are aware that, up to a recent period, the state of things was that which I suggest ; and it will be admitted that the affix M.D. conveys to the general public the impression that he who uses it is an University man, and that he combines with his medical qualification the liberal education demanded from an Arts' graduate. You may also, probably, be aware that the General Medical Council has affirmed the proposition that the M.D. should not be granted to any but the holder of a full Arts degree.

I therefore submit that the use of the letters M.D. by any University, to indicate a mere licence to practise,

amounts to the obtaining of professional credit for their licentiates from the public upon an unjustified pretence, and that it ought to be, therefore, forbidden. Medical men covet the M.D. and the title of "Doctor." Why? Because they know that it carries with it the prestige of an University education, and that that prestige counts for something in the competition for high-class practice. Is it reasonable that they should demand that prestige without earning it? And if they acquire it on such terms, how long will the Doctorate continue to carry with it the least public estimation? Already the most subordinate positions in the profession are occupied by *soi-disant* M.D.'s; and it is sufficiently evident that, if all licentiates are to be dubbed M.D., that title will, in a few years, possess no more value as a distinction than L.R.C.S. or L.F.P.S. What, then, will the profession have gained? And will not a loss have been sustained by the abrogation of a title which has been so long sought for as an University honour?

I am, Sir, yours, &c.,

ARCHIBALD H. JACOB., M.D. Dub. Univ., F.R.C.S.I.

23 Ely Place, Dublin.

COUNTY INFIRMARIES.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—The editorial note to Dr. Laffan's letter in your issue of the 24th inst. expresses exactly my opinion as regards the utility of County Infirmaries. In my last Annual Report of the Tyrone County Hospital, I alluded shortly to the disadvantages Union Hospitals labour under, as compared with County Infirmaries, and I do not consider it necessary to enter into a further discussion on the subject. Suffice it to say that I had no intention whatever of questioning the scientific skill of the workhouse medical officers; on the contrary, no one has a higher opinion of their abilities than I have. Still, I consider it quite justifiable, in the present precarious condition of the County Infirmaries, to do all I can to convince the public of the immense amount of good effected by these valuable institutions, and a strong argument in favour of their existence I believe to be the advantages they undoubtedly possess over the generality of Workhouse Hospitals. Dr. Laffan refers to the flagging supporters of this hospital. A few facts will show how entirely he is mistaken. Within the last three years, 18 new governors have subscribed to the institution; nearly £900 has been spent in the same period on improving the hospital, and supplying new beds and bedding and better furniture, and surgical instruments and appliances; 718 patients were under treatment during the year—an increase of 135, as compared with last year—50 applicants being refused admittance as unsuitable or workhouse cases. The great bulk of the profession—and, I believe, of the public—are warm supporters of the infirmaries; and it shows an amount of professional jealousy on Dr. Laffan's part, which does not speak well for his largeness of mind, to take offence where none was intended, or jump to hasty conclusions without having made himself acquainted with facts.

Yours truly,

EDWARD C. THOMPSON, M.B.,
Surgeon, Tyrone County Infirmary.

Omagh, April 26, 1878.

SUPERSTITIOUS CURES IN IRELAND.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In addition to the list of *cures*, given in your last as being popular in the South of Ireland, I may give the following contributions:—

For Scrofulous Ulcers.—The ointment of the scrofularia nodosa, also of great repute in the cure of "burnt holes" pemphigus.

Jaundice.—The patient's own urine.

As a Styptic in Bleeding Wounds.—Pig-dung.

As a Poultice for Abscesses—Cow-dung.

In these parts the infallible remedy for shingles, or herpes zoster is the application of a few drops of blood taken from any member of the family of Cahills.

Ricketts.—The application of the hand of a seventh son.

A family in the adjoining part of the county Kilkenny, named Brennan, has had bone-setters among them for considerably over a century. They are supposed to inherit the power of setting bones as a special gift, and one member who refused to exercise his gift having been killed accidentally was looked on as having suffered punishment from Providence for refusing to exercise his gift; not leaving a son, his daughters, though making no pretence to any surgical powers, are afraid to send away applicants who come to them with sprain, strain, and other injuries, without some exercise of this gift, and, accordingly, tie on bandages, adding some small prayer—I believe, a Pater Noster and Ave Maria.

I knew one man who applied parings of his toe-nail to eyelids for ulcer of the cornea.

Snail broth used to be freely taken for phthisis, but the present generation do not seem to appreciate it.

The scrapings of the bottom of an iron pot in frequent use is taken for colic—I have been told, with wonderful good effect.

I remain, &c.,

Portlaw. J. W. MARTIN.

Literature.

SHORT NOTICES.

(1) "Is our Physiology of the large Intestine Correct." By Charles J. Harris, M.R.C.S. London: Baillière, Tindall, and Cox. 1878.

(2) "Notes on the Carboniferous Cephalopoda." Part I. By William Cash, F.G.S. Leeds: McCorquodale and Co.

(3) "Fourth Annual Report on the Sanitary Condition of the Combined Sanitary Authorities of the Halifax Union." By Thomas Britton, M.D., &c.

(1) THIS pamphlet is more of a suggestive than explanatory nature. The author advances no claims or dogmatic assertions in favour of his views, but writes with the object of directing more capable minds to the subject. Some of Dr. Harris's facts are very striking, especially in reference to the practice adopted by Baker Brown, of conserving the patient's bowels after operations. The influence assigned thereby to the reduction of death-rate is open to very grave doubt. The subject is well worthy of fuller consideration. We may observe that a quotation from the *Daily Telegraph*, prefixed to a scientific paper, seems a little extraordinary, especially as this quotation does not appear to us to have a very intimate connection with the subject matter, whilst at the same time the language is rather obscure.

(2) The various geological societies, scattered throughout the country, foster and develop a taste for science, and we are indebted to such societies for many valuable contributions to palæontology; they are therefore well deserving of encouragement and support.

The Cephalopoda have excited the interest of some of our most distinguished naturalists, and this paper, read before the West Riding Geological Society, contains a most interesting *resumé* of our knowledge of them. The author well says: "that the true method of reasoning on natural objects and phenomena, is from that which is well known to that which is unknown;" hence he favours us with a description of the structure, habits, distribution, and classification of the living representatives of the class, preliminary to the study of fossil examples. These notes are evidently the work of a careful and earnest student of Nature.

We never read of this class without recalling to mind the beautiful lines from Richardson's "Geology" on the "Nautilus and the Ammonite," and his imaginary solution of the Nautilus's distribution. We quote a few verses:—

And hand in hand from Strand to Strand,
They sailed in mirth and glee,
These fairy shells, with their sister cells,
Twin sisters of the sea.

And they came at last to a sea long past,
But as they reached its shore,
The Almighty's breath spoke out in death,
And the Ammonite lived no more.

So the Nautilus now in its shelly prow,
As over the deep she strays,
Still seems to seek in bay and creek,
Its companion of other days.

(3) The remarks on over-crowding in this Report, are well deserving of the careful consideration of all medical officers of health, for we are afraid the evil and state of things described, are not confined to one district.

Dr. Britton says: "It is no unusual circumstance to see a man, his wife, and five or six children in all stages of growth, crowded into a small house of two rooms. The downstairs room serves as a kitchen and living room, and by means of a shut-up bedstead, also that of a sleeping-room. If the children were young, this would perhaps not be of so much importance, but when in many cases they are almost young men and women, this assumes a serious aspect, both from a moral and sanitary point of view." . . .

"In consequence of the number who have to sleep in one room, the beds are placed almost close together, and some are so situated as to be exposed to draughts. In order to prevent these, the chimney is blocked up, and every crevice about the window through which the air can get is carefully closed; therefore, no fresh air can enter the room, and the occupants breathe the same air over and over again."

Death and ill health are the result of the slow poisoning produced by the vitiated air. That preventable diseases arise from man's own neglect of the ordinances of Nature, and of the simplest sanitary laws, is but too well known. The work of the sanitary reformer is impeded by the culpable indifference and apathy of those most intimately concerned, but who seem reckless and regardless of the value of life and health. This picture is not a pleasant one, considering the enormous expense involved in our sanitary legislation, and it seems to prove that penal legislation will have to be resorted to, before the public will awake to the great truths of the laws of health, and the importance of their observance. The remainder of the Report is filled with the usual tables of statistics.

Medical News.

Illness of Dr. MacDowell.—We learn with satisfaction that Dr. B. F. MacDowell, of Mercer's Hospital, who has been suffering from alarming illness, is making very satisfactory progress towards convalescence, and, it is hoped, will be shortly able to resume his professional avocations.

Royal College of Physicians of London.—The following gentlemen were admitted Members on April 25th:—

Bird, William Valentine, M.D. Aberd., L.R.C.P., Sydendam, S.E.
Bogg, Thomas Wemyss, M.B. Lond., St. Leonards.
Boulton, Percy, M.D. Edin., 6 Seymour Street, W.
Gill, Stanley Augustine, Royal Lunatic Asylum, L'pool.
Saundby, Robert, M.D. Edin., Birmingham.
Savage, Geo. Henry, M.D. Lond., L.R.C.P., Bethlem Hospital, S.E.
Thorburn, John, M.D. Edin., Manchester.

Royal College of Surgeons of England.—At a quarterly meeting of the Council, holden April 18th, the following Members were elected to the Fellowship of the College:—

Fayrer, Sir Joseph, K.C.S.I., M.D., F.R.S., Granville Place; diploma of membership dated July, 1847.
Pemberton, Oliver, F.R.C.S. Ed., Temple Row, Birmingham; April, 1847.

On April 16th and 17th, the following were admitted Members of the College by Examination:—

Andrew, J. Edward, L.S.A., Victoria, Australia.
Annand, George, Melbourne, Australia.
Atkinson, John Mitford, L.S.A., Winchester.
Ball, W. Montague, L.S.A., Camden Road.
Bennett, W. C. Storer, L.R.C.P. Lond., George St., W.
Berry, F. Haycraft, Amwell Street.
Burt, Alfred, L.S.A., Ventnor, Isle of Wight.
Buxton, A. St. Clair, L.R.C.P., Shepherd's Bush.
Clabburn, Tom George, Norwich.
Clark, C. A. Dagnall, Twickenham.
Clarke, Richard, L.S.A., Henton, Oxon.
Clarke, T. Furze, L.S.A., Richmond, Surrey.
Colenso, R. John, Phillimore Gardens.
Evans, E. Prichard, Llanfabon, South Wales.
Fardon, E. Ashby, Droitwich.
Flood, F. Pultney, Leeds.
Gabb, C. Baker, L.R.C.P. Ed., Hastings.
Gilbert, P. F., The Vicarage, Cripplegate.
Giles, B. Farady, L.S.A, Canonbury.
Griffith, W. S. Anderson, Sandridge, Herts.
Henderson, Cecil, Clifton, Bristol.
Hetherington, G. Haynes, L.S.A., Uxbridge.
Higgs, Alfred, Leicester.
Lavis, H. J. Johnston, Stalbridge, Dorset.
Lockwood, C. Barrett, L.S.A., Stockton-on-Tees.
Lowson, David, M.D. Aberd., Huddersfield.
Nicholson, J. Edward, Tours.
Pearse, T. F. L.R.C.P. Lond., Finborough Rd.
Pinching, W. Wyatt, L.R.C.P. Ed., Gravesend.
Powell, Arthur Ernest, L.R.C.P. Ed., Norwich.
Prichard, J. Edward, Clifton, Bristol.
Rendall, S. Morton, Torquay, Devon.
Sayer, Thomas, Swaffham, Norfolk.
Skelding, H. John, L.S.A., Bayswater.
Sylvester, G. Holden, Tunbridge.
Takaki, Kanehiro, Tokio, Japan.
Wride, F. George, L.K.Q.C.P.I., Oxted, Cheshire.

University of St. Andrews.—The following gentlemen, having passed the required examination, obtained the degree of Doctor of Medicine, on April 18th:—

Codrington, O., M.R.C.S., L.S.A., Fort Pitt, Chatham
Colby, William Taylor, M.R.C.S.L., L.S.A., Malton, Yorkshire.
Eteson, Alfred, M.R.C.S., Watford, Herts.
Grose, Samuel, F.R.C.S., Staff-Surg. R.N., Melksham, Wilts.
Hall, Frederick, M.R.C.S.E., L.S.A., Leeds, Yorkshire.
Hicks, Henry, M.R.C.S., L.S.A., Hendon, Middlesex.
Macgowan, Alexander Thorburn, M.R.C.S., L.R.C.P., L.S.A., Clifton, Bristol.
Whalley, William, M.R.C.S., L.S.A., L.M., Bradford, Yorkshire.
Wotton, Henry, F.R.C.S., L.S.A., Kensington, London.
Wynter, Hugh Bold, M.R.C.S., L.S.A., Wandsworth Common.

At the same time, the degrees of M.B. and C.M. were obtained by—

Mackay, John Sutherland, M.A., Edinburgh.
Rea, John Henry, L.R.C.P. and S. Ed., L.M., Belfast.

University of London.—The following examiners in the Faculty of Medicine for 1878-1879 were elected at the meeting of the Senate, held on Wednesday last:—Practice of Medicine: W. H. Dickinson, M.D., and Charles Murchison, M.D., LL.D., F.R.S. Surgery: John Cooper Forster, M.B., and W. S. Savory, M.B., F.R.S. Anatomy: Prof. John Curnow, M.D., and Prof. Redfern, M.D. Physiology: Philip Henry Pye-Smith, M.D., and Prof. J. Burdon-Sanderson, M.D., F.R.S. Obstetric Medicine: J. Hall Davis, M.D., and Prof. W. S. Playfair, M.D. Materia Medica and Pharmaceutical Chemistry: Prof. E. B. Baxter, M.D., and Prof. Sydney Ringer, M.D. Forensic Medicine: Prof. Ferrier, M.D., M.A., F.R.S., and Thomas Stevenson, M.D. Hygiene, Medicine in relation to the origin and prevention of Disease, and Vital Statistics: William Farr, M.D., D.C.L., F.R.S., and John Simon, C.B., D.C.L., F.R.S. Sanitary Law and Engineering, Meteorology, and Geology: Prof. T. R. Fraser, M.D., F.R.S., and Capt. Douglas Galton, C.B., F.R.S.

NOTICES TO CORRESPONDENTS.

☞ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

READING CASES.—Cloth board cases, gilt-lettered, containing 26 strings for holding each volume of the MEDICAL PRESS AND CIRCULAR can now be had at either office of this Journal, price 2s. 6d. The postal regulations not allowing the Journal to be stitched, these cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

NOTICE TO SUBSCRIBERS.—Subscribers who have not already paid their subscriptions for last year are reminded that they are now due and should be sent to the publishers, who will be happy to acknowledge their receipt.

DR. MILNER FOTHERGILL will deliver the last lecture of the course this day (Wednesday) at 3 p.m., at the West London Hospital. Subject: "The Neurosal and Reflex Disorders of the Heart." Members of the profession and students admitted free.

MR. J. L. MILTON will deliver the first of a series of lectures on Skin Diseases at 4 p.m. this day (Wednesday) at the St. John's Hospital. Subject: "Eczema." Members of the profession and students will be supplied with cards of admission on application.

DR. HIGGINSON, Bangor, is thanked for his letter enclosing clippings of cases of hydrophobia. Our Reports being now finished we are unable to utilise them at present. In the reprint in book-form of these Reports nearly 200 typical cases will be found, the whole forming, we believe, a most exhaustive treatise on the subject.

OBSTETRICAL SOCIETY OF LONDON.—This evening (Wednesday), at 8 o'clock, Specimens: Sections of a Uterus on the first day of Menstruation, showing Desquamation of the Decidua; Section of Dysmenorrhœal Membrane, Dr. Cory; Fractured Fœtal Skull, Dr. Poole; Case of Hand-behind-head Presentation, Dr. Bryden. Papers: Dr. Braxton Hicks, "Case of Cæsarian Section;" Dr. Potter, "Case of Pregnancy complicated with Malignant Growth in Vagina and Rectum;" Dr. R. Cory, "Membranous Dysmenorrhœa."

CHEAP FOREIGN DIPLOMAS.—Our friend "Dr." Sturman will have a valuable windfall if the new Medical Act of the Government admitting foreign degrees becomes law. He has taken time by the forelock, and is already advertising "Foreign University Degrees, in our contemporary, the *Lancet*.

THE HARVEIAN SOCIETY OF LONDON.—Thursday, May 2nd, at 8½ p.m., Dr. Buzzard, "On a Case of Blepharo-spasm." Mr. E. Owen, "On a Case of Epithelioma of Rectum." Dr. John Williams, "On Cases of Fibroid Tumour treated by Hypodermic Injection of Sclarotic Acid."

PROF. SPOTTISWOODE will deliver a lecture at the Royal Institution of Great Britain on Friday next at 9 p.m., "On Polarised Light, a Nocturne in Black and Yellow."

THE POOR-LAW MEDICAL OFFICERS' ASSOCIATION.—The Annual General Meeting of this Association will be held on Tuesday next at 3 p.m., at the Freemasons' Tavern, Great Queen Street, W.C.

COMMUNICATIONS, Enclosures, &c., have been received from—Dr. John Williams, London. Dr. Davidson, Chester. Dr. Simpson, Preston. Dr. Owen, Plymouth. Dr. Dolan, Halifax. Mr. Giles, London. Mr. Swan, Dublin. Mr. G. R. Cundell, Kew. Dr. George Bland, Macclesfield. Mr. Gillingham, Chard. Dr. Stevenson Macadam, Edinburgh. The Secretary of the Obstetrical Society of London. Dr. Walker, St. Andrews. The Secretary of the Royal Society. Mr. Mosse, London. Mr. Napier, London. The Registrar-General. Mr. Evans, Liverpool. Dr. Stott, Disley, Cheshire. Mr. St. Vincent Mercier, London. Mr. Blackett, London. Dr. Mulligan, Meigh. Dr. White, Kilsheelan. Dr. White, Derry. Dr. Hanrahan, Cappaduff. Dr. Power, Borrisoleigh. Dr. Kelly, Ballindine. Dr. Lynch, Ballyneve. Dr. Mayberry, Riversdale. Dr. Fisher, Mountrath. Dr. Davy, Kimmage. Dr. Kingsley, Borrisobane. Dr. Given, Gortin. Dr. Donovan, Kinsale. Dr. McCallum, Eglinton. Dr. McManus, Trim. Dr. Davison, Elton-Bury. Dr. O'Neill, Cliffiney. Dr. Nadin, Tipperary. Dr. Mayne, Ballybrach. Dr. Moorhead, Tullamore. Dr. Duffy, Dublin. Dr. Grier, Longford. Dr. O'Neill, Dublin. Dr. Heas, Clonakilty. Dr. McDonnell, Dublin. Dr. Sterling, Castlecomer. Dr. Minchin, Dublin. Dr. Stokes, Cahir. Dr. Jacob, Maryboro'. Dr. Jones, Cork. Dr. Pullin, Sidmouth. Dr. Higginson, Bangor. Mr. Harrison, London. Mr. Hanslip Sers, Southwall, Notts. Dr. Maclaren, Stirling. Dr. Julius Althaus, London. Dr. Bodington, Kingswinford, Dudley, &c., &c.

BOOKS, PAMPHLETS, AND MEDICAL JOURNALS RECEIVED.

The Throat and its Diseases. By Lennox Browne, F.R.C.S.E. London: Baillière, Tindall, & Cox.

A Key to Organic Materia Medica. By John Muter, M.A., F.C.S. Second Edition. London: Baillière, Tindall, & Cox.

The Management and Diseases of the Dog. By R. J. Woodroffe Hill, F.R.C.V.S. London: Baillière, Tindall, & Cox.

The Whole-meal Bread Question. By W. Neave Hill.

Rational Medicine. By R. E. Dudgeon, M.D.

A Manual of Necroscopy. By A. H. Newth, M.D. London: Smith, Elder, & Co.

Anatomical Outlines. By Arthur Hensman. London: Longmans & Co.

On Infantile Paralysis. By Julius Althaus, M.D. London: Longmans, Green, & Co.

The Pathology and Treatment of Membranous Dysmenorrhœa. By John Williams.

Godlee's Atlas of Human Anatomy. Part IV.

The Westminster Review. Buffalo Medical Journal. North Carolina Medical Journal. Transactions of the Ohio State Medical Society. Students' Journal. Medical Times. Lancet. Medical Examiner. Nature. Le Progrès Medical. Canada Lancet. Journal of Psychological Medicine, &c., &c.

VACANCIES.

Bristol Royal Infirmary.—House Surgeon. Salary, £100, with board, lodging, &c. Applications, with testimonials, to the Secretary before the 11th inst.

Chelsea.—Dispenser for the Workhouse Infirmary. Salary for the outdoor poor, £70; for the indoor, £50. No other emoluments. Applictions to the Clerk to the Guardians at the Union Offices, before the 7th inst.

Gloucester General Infirmary.—Surgeon and Assistant Surgeon on the Staff. Honorary. Testimonials to the Secretary before the 30th inst.

Limerick Union Workhouse.—Visiting Medical Officer. Salary, £75. Election, the 8th inst.

Monaghan County Infirmary.—Apothecary and Registrar. Salary, £60, with apartments and allowances. Election, the 8th inst.

University College, London.—Professorship of Materia Medica. Applicants must address the Secretary to the Medical Faculty before the 15th inst.

Victoria Hospital for Children, Chelsea.—House Surgeon. Salary, £50, with board and lodging. Applications to the Secretary before the 18th inst.

Wilts County Lunatic Asylum.—Assistant Medical Officer. Salary, £110, with board, lodging, &c. Applications, endorsed outside "Applications," to the Clerk, Devizes.

APPOINTMENTS.

BAILEY, R. G., M.R.C.S.E., Junior Resident Medical Officer to the Leeds Public Dispensary.

COLLIS, R. W., L.K.Q.C.P.I. & L.M., L.R.C.S I., House Surgeon to the Lancaster Infirmary and Dispensary.

GUNN, C., M.D., L.K.Q.C.P.I., a Temporary Physician to the Cork Street Fever Hospital, Dublin.

HUNT, B., M.D., M.R.C.P.L., a Physician to the Queen's Hospital, Birmingham.

JAQUET, J. L., M.R.C.S.E., House Physician to the Westminster Hospital.

MACKAY, W. B., L.R.C.S.I., &c., Medical Officer to the Glencullen Dispensary, Rathdown Union.

MOORE, J. D., M.D., of Lancaster, Visitor of all Houses licensed for the reception of Lunatics within the West Riding of Yorkshire.

RICHARDSON, W., M.B., C.M., Assistant Medical Officer to the Crichton Royal Institution, Dumfries.

SOUTHAM, F. A., M.B., F.R.C.S.E., Resident Surgical Officer to the Royal Infirmary, Manchester.

STEAVENSON, W. E., M.R.C.S.E., a House Physician to St. Bartholomew's Hospital.

STEELL, G., M.D., Resident Medical Officer to the Royal Infirmary, Manchester.

Births.

DICKSON.—April 27th, at Moradabad, India, the wife of Lindsay F. Dickson, M.D., Surgeon Major, of a daughter.

ELWIN.—April 26, at 6 City Road, London, the wife of C. J. Elwin, M.R.C.S., of a daughter.

PIGGOT.—April 24, at Beckenham, Kent, the wife of Allen Piggot, L.R.C.P., M.R.C.S., of a son.

Marriages.

BROWN—SINCLAIR.—April 24, at the Presbyterian Church, Dublin, Thomas J. Brown, A.B., M.B., T.C.D., &c., Dungannon, to Sarah, youngest daughter of William Sinclair, of Warrenpoint, co. Down.

ELLIOTT—WAKEFIELD.—April 25, at Wellington, Somerset, Christopher Elliott, M.D., of Redland, Bristol, to Rachel, only daughter of J. E. Wakefield, of Wellington.

HARDWICKE—BALDRY.—April 24, at Chelsea, W. Wright Hardwicke, M.R.C.P., of Rotheram, to Alice Mary, daughter of J. D. Baldry, of Carlyle Square, S.W.

WILSON—MORRISON.—April 25, at St. Luke's, Westbourne Park, W., C. W. Wilson, M.B., of Cullercoats, Northumberland, to Eleanor daughter of J. Morrison, of Tynemouth.

Deaths.

CURTLER.—On April 6, at Droitwich, Henry Curtler, M.R.C.S.E., aged 41.

EDMONDS.—On April 5, at Ashby-de-la-Zouch, Spencer Edmonds, M.R.C.S.E., aged 45.

FLETCHER.—On April 3, at Bury New Road, Broughton, Lancashire, Matthew Fletcher, M.R.C.S.E., aged 83.

GIRLING.—On April 4, at Eynsford, Norfolk, Christopher Andrews Girling, M.R.C.S.E., aged 73.

JACKSON.—On April 23, at Harley Street, Cavendish Square, Thomas Carr Jackson, F.R.C.S., aged 55.

LEAKE.—On April 14, at Rathkeale House, Girdler's Road, Brookgreen, Jonas R. Leake, L.R.C.P.Ed., aged 34.

MACAW.—On April 9, at the Institution for the Insane, Coton Hill, near Stafford, Kennedy Macaw, M.D., aged 39.

MACKENZIE.—On April 13, at Kelso, William Maclean Mackenzie, M.D., aged 59.

MARTIN.—On April 10, at Evesham, Anthony Martin, M.R.C.S.E., aged 64.

STOTT.—On April 8, at Disley, Cheshire, Walter Barton Stott, M.R.C.S., aged 78.

IRISH POOR-LAW INTELLIGENCE.

THE ABUSE OF DISPENSARY TICKETS IN IRELAND.

THE Council of the Irish Medical Association have for some months been engaged upon the consideration of this very important subject. Some time ago it was decided by them to take—so far as was possible—the opinion of the Poor-law Medical Officers of Ireland as to the most feasible means of relieving the medical officers and the ratepayers of the burthen laid upon them by those who abuse the relief system, and accordingly a circular letter was addressed to every dispensary doctor in Ireland, in which several suggestions were submitted for his consideration, and his opinion thereon was requested. Having received a large number of replies, the Council proceeded to apply the information thus acquired to the construction of a scheme for, at least, a partial remedy of these abuses. This work was undertaken with the more anxiety because the Council was anxious to lay before the Poor-law Enquiry—or Union Amalgamation—Commission some feasible arrangement for the desired purpose, in the hope that the Commissioners would adopt it, or, at least, submit it to Parliament with their report. The Irish Medical Association has completed its consideration of the subject, and has now submitted the result of its deliberations to the Commissioners in the form of a letter.

The Council point out that when the Medical Charities' Act passed in 1851, the working classes in Ireland were in a very impoverished condition so far as medical relief was concerned, and were dependent upon institutions supported by voluntary contributions. The poor were in the habit of obtaining relief in these institutions by the mere recommendation of subscribers, irrespective of the degree of their poverty. Under these circumstances, on the passing of the Act, it was considered that dispensary medical relief should be easily obtainable, and that the committee of management of the dispensaries should have the power of ordering medical relief equivalent to that possessed by the managers and subscribers under the old voluntary dispensary system.

The state of things which existed at the time of the passing of the Medical Charities' Act, has now passed away, and almost all the subscribers and managers of the old voluntary dispensaries have passed away too. The working classes of Ireland are in a much better position than they were at that time; and the position of the Irish artisan, labourer, or cotter-farmer, may now be considered as good, relatively, as the position of similar persons in England. Taking the present condition of the working classes in Ireland into consideration, the Council are of opinion that medical relief under the Poor-laws should be administered in Ireland upon similar principles to those acted upon in England, namely, that while everyone too poor to pay for medical attendance should be able to obtain efficient attendance easily at the public expense; yet persons able to contribute towards the expense of medical attendance, either through provident dispensaries or sick clubs, or by direct fees to medical practitioners, should not be permitted to obtain gratuitous advice, except in cases of great emergency.

The Council then proceeds to point out the complete inadequacy of the present system to obviate the misuse of dispensary tickets. They have, it is stated, ascertained that tickets are so easily obtained that practically there is little difficulty, in the majority of districts, in anyone procuring a ticket. They also find that there is great difficulty in getting improperly issued tickets cancelled by the Committee, partly on account of the *long intervals* between the meetings of the Committee, and partly through the unwillingness of the members of the Committee to censure their fellow-members by cancelling tickets issued by them. This is, to a certain extent, demonstrated by the small number of cancelled tickets reported to the Local Government Board. The report of the Board shows that the number of tickets cancelled is only about 500 out of a total of nearly three-quarters of a million per annum issued in the whole of Ireland, while the abuse of dispensary relief is notorious in almost every district.

The cancelling of tickets is almost useless, as the patient has had the attendance of the dispensary medical officer, who is responsible for the case, which has generally terminated long before the dispensary committee holds a meeting, and tickets are frequently re-issued for the same individual immediately after the previous one had been cancelled; therefore the Council consider that the following portion of section 9, cap. 68, 14 and 15 Vict., "Provided always that if any person who shall obtain a ticket . . . . shall be declared by a majority of the members then present not to be a fit object for dispensary relief, the ticket shall be cancelled, and *the holder thereof disentitled to further relief*," should be read and acted upon in its literal sense.

Before offering any suggestions with the object of limiting the number of persons entitled to sick relief, the Council naturally looks to the means of supplying the better class of "poor" persons with that medical advice and attendance which they now obtain at the public expense, and—equally naturally—they adopt the means which have been found efficacious in England, and which do actually now secure in that division of the kingdom to such classes all the medical care they can desire.

The Council express their regret to find, on inquiry, that little or but feeble attempts have been made by working people in Ireland to found sick clubs, or provinent dispensaries, as in England; and they attribute this want o

independence on their part to the fact that so long as free medical attendance is obtainable by almost everyone, as at present, there is no inducement to the people to provide for their own wants out of their own pockets. The inquiries of the Council with regard to gratuitous medical relief in England have proved that wherever free relief is too easily obtainable, either no attempt has been made to establish provident dispensaries, or where such an attempt has been made, it has failed.

The Council also have ascertained that a large number of the dispensary medical officers in Ireland are willing to attend comparatively poor persons at a reduced rate.

This last paragraph is, in our opinion, the most important of the letter, and we ask for it the attentive consideration of the Poor-law Medical Officers. When dispensary doctors give reasonable expression to their discontent at the promiscuous granting of red tickets, they are not unfrequently met by the reply of the issuer: "Well! What was I to do? I know that this poor man is able to pay five shillings, or by borrowing might perhaps manage ten shillings, but I know he could not give £1; and, as I believe you would not attend him for less, I was obliged to give him a dispensary ticket or leave him to suffer uncared for." Now we are fully aware that there are but few of the cotter-farmer class, who, being habitually red-ticket patients, could not find £1 for the doctor if they pleased, and we know well that many of those who look upon gratis medical relief as their right, are never short of £1 when it is wanted for a religious oblation, a petty sessions law suit, a wake, or a wedding. Nevertheless, there are, undoubtedly, "poor" persons who would be able and willing to pay a small fee, but not disposed to part with £1 for the opening of a whitlow or some equally unimportant operation. The question is, Is the profession, as a whole, willing to meet the necessities of such persons by accepting a fee proportioned to their circumstances; or would they, on the contrary, deem it a better course to continue their gratis attendance on such persons while adhering to the £1 fee in all other cases?

Our Irish readers are, no doubt, aware that in the English provinces it is usual for the medical men of a district to agree amongst themselves to accept fees according to a scale, proportionate to the house valuation of the patient, and those "poor" persons who have no such valuation, are provided for by clubs and provident dispensaries, which produce to the medical man a fair return for his labour amongst the class, who in Ireland, pay not one penny for medical care. We are not forgetful that the adaptability of such a system must depend greatly upon the circumstances of the individual medical man, who, in some instances, may be able to command his price, and may prefer small business and large profits, while, in other cases, he may be disposed to work hard at small fees in order to put together a respectable aggregate income. We are, nevertheless, alive to the fact that many medical men who now adhere rigidly to the £1 fee, would gladly accept a lower honorarium if they were relieved (by a decided expression of opinion on the part of the profession) from the apprehension that their doing so would lower them in the eyes of their brethren. It is not surprising, considering the traditions under which the profession in Ireland has hitherto worked, that the Council f the Irish Medical Association should have hesitated to offer such a suggestion as the modification offers, but the individual members of the profession in the Irish provinces can relieve the Council of this hesitation by thinking over the applicability of such a proposal to their own state, and expressing their views thereon.

(To be continued.)

TRALEE BOARD OF GUARDIANS.

THE minutes of an extraordinary meeting of the Brosna dispensary committee were read, and resolutions were adopted:—"That the resignation of Dr. Harrold be accepted, subject to his discharging the duties for one month."

Proposed, That the committee recommend the guardians to give Dr. Harrold £60 a year superannuation, but this was negatived by the following resolution, which was passed by a majority of two:—"That considering Dr. Harrold's physical appearance and strength, he has no claim for superannuation."

ABBEYLEIX UNION.

APPOINTMENT OF AN APOTHECARY AND CHLOROFORMIST.

THE business for consideration was whether the appointment of apothecary to this workhouse is required; and if so that Dr. Swan be requested to accept the office in connection with his own appointment as medical officer of this house, and that he be paid for same.

The Clerk said he advertised for an apothecary, but had received no applications.

Mr. Fleming would rather pay extra so as to induce an apothecary to come to live in the town, which would be a great convenience to the people at large.

Mr. Owen said the late apothecary informed him that an apothecary's establishment did not pay in Abbeyleix.

Dr. Swan was then called into the board-room, and asked if he would accept the duty. He declined, but in reply to the Chairman, he said if Dr. Stoney would combine the office with that of chloroformist, which he at present held, it would be a great advantage.

Proposed and seconded, that the salary for the two offices be £50—£40 for apothecary, same as they paid the late doctor, and £10 for chloroformist.

Amendment, that the salary be £40 for both.

A vote was then taken, when there appeared—For giving £40, 14.—For giving £50, 11.

The salary was therefore fixed at £40.

The Chairman, to Dr. Stoney (who had been called in), observed that the board were just after having a vote on the salary they would give, and had decided for £40—£30 for apothecary, and £10 as chloroformist to Dr. Swan.

Dr. Stoney said he supposed he had no option but to take it. Subsequently, after conversing with some guardians in the vicinity of the chair, he withdrew this answer, and said he was entitled to at least as much salary as the late apothecary, and would not take less than £50. Finally he consented to take the £40, after consulting with some of his friends, and the subject dropped.

WATERFORD UNION—KILMEADEN DISPENSARY.

PROPOSED DECREASE OF SALARY.

THE L.G.B. forwarded a copy of a letter they had sent to the committee:—

SIR,—The L.G.B. acknowledge the receipt of your minutes of the 5th instant, and a copy of advertisement directed to be issued for a medical officer to supply the vacancy created by the death of Dr. Baldwin; and with reference thereto, that the salary attached to the office be be reduced to £100 a year, the Board desire to point out that the salary is £120, as fixed by the guardians and approved by the L.G.B. (Art. 24, Dispensary Regulations)

and remains at that amount until altered in usual course of procedure. Queries are transmitted herewith respecting the gentleman who may be appointed to the vacant office, which you will be good enough to return when duly signed and answered, together with his diploma, &c., &c.

By order, B. BANKS.

Mr. Clampett did not believe in the L.G.B. blowing hot and cold, and acting in a very inconsistent manner in these matters of salaries. The guardians fixed the late clerk's salary at £160, by resolution, and when they advertised for a new clerk, they did so at a salary of £50 a year less, without notice, and yet the L.G.B. never set that arrangement aside. He would move that their attention be called to their inconsistency.

Captain Power had often heard Mr. Clampett say he was glad to have the L.G.B. to control them. Kilmeaden was a very miserable place, and there was no use in comparing the doctor with the clerk, who had three times the salary of the medical officer. There was no private practice in it, and £100 a year, under the circumstances, would be a starvation allowance.

Mr. Clampett—I don't care if he gets £250, but I wish that we should stand on principle.

Mr. Elliott—That is an interference of the L.G.B. with a representative body, that is disgraceful.

Mr. Leamy—And they will always interfere.

Mr. Elliott—They will get hundreds of men at £100 a year.

A vote was called for on Mr. Clampett's resolution, which was taken with the following result:—For, 7. Against, 5. Did not vote, 1.

DOCTOR'S FEES.

In reference to the paying of three guineas to Dr. Flynn, for three days' services, it was moved that he be paid at the rate of three guineas per week was passed. This made £1 7s., which was ordered to be paid.

Mr. Wall—They will come in only for one hour, and they must be paid three guineas.

Mr. Curran—We care for justice and nothing else. It appeared from a letter of Mr. Anthony, hon. sec. of the Ringville dispensary, that the arrangement with Dr. Flynn was three guineas per week.

The Clerk read the act, which specified that it was the board of guardians who had the power of giving a rate of remuneration.

Chairman—I would make one remark, that in cases of this sort Dr. Redmond was employed for Dr. Hartland to do his duty, and I don't see why we should give Dr. Flynn more than Dr. Redmond. As we are on this subject, I would say that when a doctor gets leave he should have a medical certificate, to show that he was sick (hear).

This was agreed to, and ordered to be inserted in the minutes.

Clerk—It would create an admirable *corps d'sprit*, if you would make the doctors pay their temporary substitutes.

[This Clerk of Union's knowledge of the law and the regulations is, apparently, not more complete than that of his French. When he undertakes to advise the guardians he might, with advantage, consult the 22nd article of the Dispensary Regulations, from which he will find that the guardians have no more right to refuse payment of a medical substitute than, he (the Clerk) has, to decline payment for his boots. If the dispensary doctor, being sick, has the good sense to do nothing more than the regulations gulations require, the guardians *must* pay, and the advice gratis of the Clerk to them is, therefore, of not the least value.

ROYAL MEDICAL BENEVOLENT FUND SOCIETY FOR IRELAND.—BELFAST BRANCH.

THE quarterly meeting of this society was held on April 17th, Dr. T. H. Purdon in the chair. Several applications were submitted for the consideration of the meeting, with a view to transmission to the parent committee for placing on the roll for grants, and five cases were approved of as suitable to receive assistance. All of them were cases of widows of deceased physicians or surgeons. It was remarked that no applications for aid had been received from any medical man within the bounds of the branch for many years, all medical gentlemen having connection with this branch of the society being aid-givers and none aid-receivers. The society is purely benevolent in its operations, and it would be difficult to estimate the amount of good it has accomplished during the three dozen years it has been in existence.

MOUNTMELICK UNION.

PROPOSED REDUCTION OF THE SALARIES OF THE SANITARY OFFICERS.

SOME time ago a motion for the reduction of the salaries of the sanitary officers of the union was brought forward. The motion was carried, and its effect was to reduce the salaries of the sanitary sub-officers from £7 10s. to £5; of the sanitary officers from £20 to £15, and of the consulting sanitary officers from £20 to £5. No notice of the reduction having been taken by the L.G.B., the acting clerk wrote to ask if he were to pay them the usual salary for the quarter ending 25th ult. The L.G.B. now wrote to have him do so, as the proposed reduction had not been sanctioned by them.

DR. WILKINSON'S SUPERANNUATION.

The following letter was received from the L.G B.:—

Local Government Board, Dublin,
12th April, 1878.

SIR,—Adverting to previous correspondence relating to the proposed superannuation of Dr. Wilkinson, late medical officer of the Clonaslee dispensary district, the L.G.B. desire to acquaint the board of guardians that they have received a report from their inspector, Dr. Burke, on the subject, from which it appears that the requirements of the law as regards the notice of motion in this case were complied with, and that the proceedings of the board on the 2nd February last in connection with this matter were both regular and valid.

Nevertheless, having regard to the diversity of opinion on the subject which seems to exist as shown by the conflicting proposals made on the 9th and 16th February, and 6th inst., the L.G.B. think that it will be more satisfactory under all the circumstances that the proceedings should take place *de novo*, particular care being now taken that all the requirements of the statute are particularly attended to.—By order, &c., B. BANKS, Sec.

To the Acting Clerk.

Mr. Cobbe said he had not words at his command strong enough to condemn the vacillating policy of the L.G.B. He thought they had a right to call on their county member to put a question in parliament to the president of the L.G.B. as to whether he sanctioned such proceedings, and whether Ireland was to be governed by a body who seemed to aim at nothing but how to increase taxation?

The Chairman said the best way was not to notice the L.G.B.'s letter. The superannuation had been fixed at £52 this day week, and would so remain until altered by a fresh resolution.

Mr. Cullen remarked that the guardians had a right to insist that when anything was done it should be done on principles of equity and justice. The L.G.B. ignored those principles, and gave great room for complaint in all their dealings with this board.

Eventually, Mr. Cobbe put forward a motion confirming the superannuation of £52 a year fixed this day week, and requesting the L.G.B. to sanction it.

The motion was adopted unanimously.

THE INCREASE TO DR. TABUTEAU'S SALARY.

The following letter was read:—

Local Government Board, Dublin,
12th April, 1878.

SIR,—The L.G.B. have had before them the resolution

of the board of guardians of Mountmelick union of the 23rd ult., that the resolution be rescinded by which the salary of Dr. Tabuteau, medical officer of the Cloneygowan dispensary district, was increased by £20 per annum, and the Board desire to state that the increase in the salary of Dr. Tabuteau was carried by a large majority at a meeting specially convened by notice for the purpose of considering the question, and ample time was allowed from the date of the meeting, 2nd February, to the date of the Board's letter sanctioning the increase—the 8th March—to reconsider the subject. Dr. Tabuteau's salary at the increased rate is payable from the 2nd February.

By order, &c., B. BANKS, Sec.

Mr. Cullen—I think there was never a more unjust decision than this. Dr. Tabuteau gets £20 a year for doing what Dr. Fisher had to do for £3, and the ratepayers have to pay both.

The subject then dropped, but at a later stage, a resolution was passed at the instance of Mr. Cobbe, showing that the reduction of the increase of Dr. Tabuteau's salary to £10 was carried on a legal notice of motion.

This subject came before the Board again to-day (April 20) in the form of a letter from the L. G. B., who decline to sanction the reduction (from £20 to £10) of the increase of salary lately voted Dr. Tabuteau.

The letter was marked "read."

SUPERANNUATION.

The L. G. B. wrote to the effect that they were still of opinion that the proceedings in connection with the superannuation allowance to Dr. Wilkinson should commence *de novo*. They urged the guardians to adopt that course.

Proposed—"That the guardians having considered the circumstances of the case so often, were of opinion that the amount carried and confirmed on the 6th and 18th April—viz., £52—is quite sufficient; and we again beg to request the sanction of the said sum by the L.G.B."

Mr. Kemmis suggested that the words "quite sufficient" be omitted from the resolution. He certainly did not think £52 was sufficient. At the time the question was before the Board he proposed a middle course.

The words suggested by Me. Kemmis were omitted from the resolution, and it was then put from the chair and carried.

At a later stage of the proceedings Mr. Phillips entered the Board-room, and handed in a notice of motion that he would on the 25th of May move that a superannuation allowance of £86 1s. 1d. be granted to Dr. Wilkinson.

NORTH DUBLIN UNION.

SMALL-POX.

ONE of the relieving officers reported that an application was made to remove a case of small-pox from Sackville Street to the Mater Misericordiæ Hospital, and when he sent the case to the hospital it was refused admission owing to the want of accommodation. It was then sent to the Hardwicke Hospital, and was also refused admission there, there being no vacant beds. The case was then sent to the Cork Street Hospital, and was admitted there.

The Chairman said this was an illustration of the necessity of the South Dublin Union doing what they had requested them to do—to leave the Cork Street Hospital for cases in the South Union, and the Hardwicke Hospital for the cases arising in the North Union, while the Mater Misericordiæ received cases from both. They had declined to do that and stood on their rights, and here is the result—a small-pox patient hawked about the city. Naturally, people would go to the nearest hospital, and it was a very important thing that they should be taken to the nearest hospital, but that would be impossible if the present system went on (hear, hear).

Mr. Roper moved—

"That the attention of the L.G.B. be directed to the report, and to the suggestion made by this board to the board of the South Union, asking them to have the Hardwicke Hospital for the accommodation of small-pox patients on the north side, and to the reply thereto; and that the L.G.B. be asked to use their influence to induce the South Union board to carry out our suggestion."

Carried unanimously.

ABNORMALITIES OF FŒTAL DEVELOPMENT. (a)

By AUGUSTUS J. PEPPER, M.B., M.S., F.R.C.S.,
Pathologist to St. Mary's Hospital.

The subject I have chosen for my paper this evening is one which, I think, has not received the attention it has deserved at the hands of pathologists. It is one that may not have any great or direct practical bearing on the treatment of disease, but indirectly it throws a good deal of light on the manner in which diseased conditions have their origin, for if we could wish to study any subject completely and thoroughly, we should combine the analytical and synthetic methods of research; since we get a much clearer insight into the complex workings of nature by ascertaining how she composes as well as resolves the elements at her disposal. We should inquire into development and growth, and not simply confine ourselves to waste and decay. For this reason I have thought fit to discuss some points concerning abnormal conditions of fœtal development, partly because they explain certain malformations met with in medical practice, partly on account of the support they give to what has been observed to be the order of the changes that occur in the formation of the several tissues and organs of the body; and lastly, because they lend some assistance to the interpretation of pathological changes.

You will forgive me for calling your attention to one or two facts relative to the study of normal embryonic changes.

1st. That after the primary segmentation of the cells of the ovum, there occurs a differentiation of these cells into three laminæ, which have received the names of Epiblast, Mesoblast, and Hypoblast, and that from these laminæ the several structures of the body are built.

2nd. That in the earlier stages the developmental force appears to be chiefly directed to the production of the cranio-spinal axis, the cerebro-spinal nervous system; and the structures that are connected with them, by similarity of formative changes, and correlation of function.

3rd. That there does not seem to be that amount of interdependence between anatomically related parts, as obtains when the different organs and systems of organs have assumed their full functional activity; *e.g.*, take the case of the nervous and muscular systems; here we know that after the fœtus has assumed a separate existence, altered nutritive conditions of one may lead to analogous changes in the other, such as wasting of the muscles of expression in rheumatic facial paralysis, or the late rigidity that occurs in the limbs as the result of descending degeneration of the cord, secondary to a widespread cerebral lesion.

These conditions should be borne in mind when we are investigating the question of the *rationale* of malformations; for by knowing that there are three distinct embryonic layers, and that by a sure law certain tissues only are developed from those layers, we can infer with a certain amount of accuracy what will be the result, should there be a divergence from the ordinary course of development. And, moreover, as at the commencement of the formation of distinct structures, the nervous system and appendages figure so prominently, so we should expect (as is really the case) that malformations would implicate them to a very great extent. Again, from the third axiom, we should not be likely to find that non-development of one part necessarily involved, either at the same time, or by way of secondary degenerative change, other parts functionally related to it. From observations that I have recently made on the subject, I have been able to confirm the statements that have just been made.

I propose in the first place, to deal with the question of errors in development, involving the cephalic and spinal centres together with the osseous and membranous structures that lodge and protect them. The deformity most frequently observed is that of spina bifida, its analogue, meningocele, being of much rarer occurrence.

(a) Read before the Harveian Society.

Here there is an arrest of development at that stage when the permanent vertebræ, muscle-plates, and spinal ganglia are being formed from the proto-vertebral segments. This arrest tells mainly on the part of the mesoblast, from which the posterior segments of the vertebræ (*i.e.*, the neural arches, spines, and transverse processes of the neural arches) are derived. The result, with slight variations as to the number and character of the coverings of the congenital tumour, is pretty uniform. It is this—that instead of there being a resisting bony casework, supporting the contents of the neural canal, this casework remains in the membranous state, which favours any distending force from within, to cause a bulging or diverticulum from the spinal canal. This force is hydrostatic in nature, and consists of the uniform pressure of the cerebro-spinal fluid contained in what Mr. Hilton terms the external arachnoid. The pressure and resistance being uniform, so is the outline of the resulting tumour. Now, it is well known as a clinical fact that spina bifida is not unfrequently associated with chronic hydrocephalus, and my observations have led me to conclude that there is something more than a mere coincidence of the two abnormal conditions; that, in truth, each one acts upon the other, and helps to increase and perpetuate it. The intermediate factor is a closure of the aperture in the pia mater, which forms the communication between the subarachnoid space at the base of the brain, and the ventricular cavities within; or else an obstruction of the Sylvian aqueduct. Now, as you are aware the patency of this communication is very important to the well-being of the individual, for it is the permanent check upon the tendency to undue internal pressure on the brain-substance during expiration, which, causing increased obstruction to the escape of blood from the head, increases the tension within. The counteracting element of this abnormal pressure, is the possibility of escape of the cerebro-spinal fluid from the ventricles to the base of the brain and spinal canal. In cases of spina bifida and hydrocephalus, where the aperture is closed, we have evidence in the fact that pressure on the cranium at the site of the sutures and fontanelles, does not cause increase of tension in the walls of the spina bifida. In other cases, where the pia-matral aperture is open, gentle continued pressure on either spina bifida or cranium will bring about an increased fulness in the other.

The former condition I lately witnessed at an autopsy I made—the particulars of which may be briefly narrated.

E. B., aged 8 months, was born with a small swelling at the lower part of the back, but with no apparent enlargement of the head. When two months of age, increase in size, both of the spinal tumour and the cranium, was observed, and this continued to get worse till the patient's death. At the *post-mortem* examination, I found the circumference of the head to be 24 inches; pressure on the spina bifida (which was as large as a small orange) emptied it of its fluid contents, which counterpressure on the cranium failed to prevent, and also failed to cause a refilling of the sac. Nor could any fluctuation be detected between the two. More than a quart of clear fluid was removed from the ventricles, which proved on physical and chemical examination to be cerebro-spinal. The brain weighed 24 ounces, that is 1½ oz. below the average. The aqueduct of Sylvius was widely open, but the aperture from the subarachnoid space to the fourth ventricle was closed, so that the communication between the two was abolished; and what I wish to draw your attention to is the inference that the absence of the natural ebb and flow of the cerebro-spinal fluid led to such a rapidly recurring irregularity of vascular pressure, that eventually extensive effusion took place from the lining membrane of the ventricles in the brain, and the external arachnoid in the spinal canal. In the former, the result was wide separation of the sutures, and enlargement of the fontanelles; in the latter, increase in size of the spina bifida.

Meningocele, an analogous condition affecting the cranial walls, may be met with in several positions. I have only seen it in the suboccipital region, but a case is on record where it occurred at the root of the nose, and was mistaken for a nævus, and operated on, an accident fraught with danger, and which alone would be sufficient to justify a careful study of abnormalities in development.

In spina bifida, there occasionally exists a defective innervation and development of the lower limbs, which may involve one or both. It may be that the defect only goes so far as to give rise to a stunted growth, with diminished power in the extremity, or the lesion may be more decided; in fact, we may get an actual deformity, such as talipes calcaneus. About two years ago, I saw Mr. Callender perform Syme's amputation for caries of the tarsus, on an adult patient, the subject of a cured lumbar-spina-bifida, in whom the growth of one lower extremity was decidedly below par. I mention this case because such have been adduced as proof that the defective organisation of the limbs may be due to what is termed a fœtal myelitis, a conclusion it seems to me altogether erroneous.

I would ask you to look at the fœtus before you, and you will see there is decided indication of talipes calcaneus. Before being hardened by preservation in spirit, the dorsum of the foot could easily be brought into contact with the anterior surface of the leg, whilst it could only be extended to a right angle. In the same specimens, there is contraction of one finger, and absence of a part of the anterior abdominal wall. Now, the spinal cord is conspicuous only by its absence, and I think I may affirm without fear of contradiction that these multiple malformations could not have been at any time the result of inflammation of the cord. The real explanation may probably be found in the assumption that they are all due to some general freak of nature, and owed their origin to a common cause. Billroth denies their myelitic descent.

At the beginning of this paper I stated that there did not appear to be such a close functional relation between structures anatomically connected, in the fœtal condition, as afterwards; and this fits in with the theory, that although congenital deformities of the limbs are not dependent on a preceding abnormality of the nerve centres, yet when subsequently the two come to act in concert, there grows up between them such an interdependence that a diseased condition of one will entail a continuation, or even an increase of a diseased condition of the other. In other words, a club-foot or "wasted limb," congenitally associated with defective or altered innervation, may increase in severity. Quite recently, Dr. Gowers had a patient under his care with congenital absence of part of one upper limb, and at the autopsy, a decided difference was observed between the ascending parietal convolution, and parietal lobule, in the two hemispheres of the brain. Here it might be said that the ill-developed nerve centre had led to abnormal development of the upper extremity. I think the reverse to be more probably the correct explanation, *i.e.*, the malformation of the arm was primary, and the diminution in size of the associated nerve centre secondary, this having lost, or rather never having possessed, its functional relationship. This case is further of great interest, inasmuch as it gave pretty conclusive evidence of the cerebral localisation, in connection with a definite defective development; and evidence such as this is all the more valuable as it is less likely to be vitiated by disturbing elements, such as are so commonly obtained where the lesion is acquired, and especially if suddenly brought about. A short time since, I made a *post-mortem* examination, where the patient died from severe injury to the head; previous to death, there was paralysis of the left arm only, as he firmly resisted any attempt at passive movement made on the other extremities. At the autopsy, superficial laceration of the ascending parietal convolution of the right side was the only injury in the brain that could be detected. I mention this, as it furnishes confirmation of what has been said of the localisation of function in the cerebral hemispheres, observed in the case of congenital malformation of the upper limb.

Whilst I am speaking of malformations of the cranio-

spinal axis and centre, I may describe in a few words the deformity that was present in a girl aged 9 years, a patient of Mr. Berkeley Hill. I show you her photograph. In the lower dorsal region there is a firm solid pedunculated swelling, the size of a walnut, having a deep connection with the spine. There is little doubt but that it is a cured spina bifida, for associated with it is a remarkable malformation of the sides of the vertebræ and contiguous ribs, leading to marked lateral curvature of the spine. The lateral parts of two or three vertebræ were abnormally small, and irregular in outline, and instead of the ribs being distinct and well formed they are fused at one part into a continuous mass. The muscles by the side of the spine are ill-developed. The interest in this case was the light thrown by the costal irregularity on the diagnosis of the tumour over the spine, and also to the support it lends to the embryological observation that the rudiments of the ribs are derived from the same fœtal lamina as the vertebræ and spinal muscles and ganglia.

Two specimens of anencephalous fœtuses (one of which I exhibit) suggested the subject of my discourse this evening. It is not necessary that I should dwell on the state of the crania; suffice it to say that the vault of each was almost entirely absent, except what remained in a membranous condition. The supra-orbitals, however, were present, although much smaller than natural, so that the eyeballs, as is usual in such cases, were very prominent.

In case No. I., born at full term, and which breathed a few minutes, the central part of the membranous roof of the skull was the seat of three or four cysts, from the size of a pea to a small nut. The inner wall of these was lined with squamous epithelium (endothelium), as the microscopical specimen A shows. It has been stained with silver nitrate. These closed cysts, I suspect, must have been derived from the arachnoid sac, and the explanation of their origin as follows: separate layers of cells being set aside for the formation of the walls of the arachnoid, if we suppose these to continue in their development beyond the period at which those for the subjacent nerve centre ceased, one of two things must have taken place: 1, either a single protrusion from the cephalic bend; or, 2, an involution of the membrane. The latter was what happened here, and in addition to the inflexion, adhesions must have formed between contiguous folds, so that closed spaces resulted. A process of analogous nature is observed in the normal development of the central canal and posterior median fissure of the spinal cord.

In the same fœtus the brain was absent, with the exception of the medulla oblongata, with the 8th and 9th nerves of Willis attached. There was no trace of an olfactory nerve, and the optic was greatly attenuated, so that it appeared only as a fine fibrous band. The other cranial nerves were well developed. It at first sight appears strange that the first and second nerves should alone fail to be present, but if the order of their development be kept in view, the difficulty may be in some degree explained. From the latest researches of embryologists, it has been concluded not only by inference, but also from observation, that the cranial nerves, with the exception of the optic and olfactory, are derived from a different layer of the blastoderm from that whence the brain is formed, and that it is by a process of fusion that the nerves become subsequently united to the encephalon.

Now should the brain itself be absent, it would not be surprising that the olfactory nerve were absent too, nor that the optic should be other than a filamentous band, seeing that all are developed from the same epiblastic layer. An objection, I can conceive, might be raised in such terms as these:—The primary optic vesicle from which certain fundamental parts of the eye are formed, gives origin also to the optic nerves, and if one should suffer, why not the other? I contend that the apparent anomaly supports the theory that each structure possesses its own developmental activity, and that this autonomy is retained by the distal part of the optic vesicle after the proximal part and the cerebral vesicle, from which the optic is an offshoot, have disappeared; and the fact of the eye being normal in structure, whilst the brain from which it is in part derived is absent, would tend to show that it is not a matter of absolute non-development, but that a degenerative change had succeeded to its primary stages. At the same time, should various parts of the cranium, cerebro-spinal axis, nerves and appendages be found at fault, we should certainly expect to find a certain amount of order in the disorder of nature; and that structures related anatomically and physiologically would be more likely to be associated in any developmental error than where no such relation exists.

In the case I am now discussing, the spinal canal presented the normal characters, but on making a transverse section of the cord, an unmistakable patch of degeneration was seen in the posterior column, running outwards from the grey commissure, but not reaching to the surface. This patch presented a semi-translucent appearance, and contrasted strongly with the dead white colour of the columns in general. Its position was found on careful examination to vary in different parts of the cord. Thus, in the mid-cervical region, it bordered closely on the large central canal, and was irregular in outline; in the upper dorsal, it occupied more definitely the left white posterior column, whilst in the lower dorsal both sides were affected, the disease skirting the posterior median fissure. In the two former positions this could be distinctly seen by the naked eye, and in all was very obvious on microscopical examination. By hardening the specimens in spirit, and making sections, the central part of the degenerated area disappeared to some extent, *i.e.*, there was so little cohesion between the particles of granular *débris* that they crumbled away. The greater part, however, remained, and proved to consist of ill-formed connective tissue, in and around which were blood-vessels of larger size than elsewhere in the cord. Not a trace of nerve fibre was left, not even the resisting axis-cylinders. Now this condition so fully resembled the later stages of degeneration of the cord ascending or descending, that one was naturally led to inquire whether it was not a case of the former, *i.e.*, whether it was not a *secondary* retrograde metamorphosis, depending on a central lesion above. This could not be substantiated, and I came to the conclusion that it was a primary local degeneration, and nothing more. If you look at the microscopical specimen B, you will see that the large ganglion cells of the anterior horn of the grey matter, though granular, are fairly developed, and the axis-cylinders (best seen in the posterior columns, for here the section is thinner than elsewhere) quite distinct. One circumstance somewhat obscures the differentiation, viz., that the tissues generally are infiltrated with nuclei, not as the product of a diseased condition, but of a normal embryonal state. This is seen whether the areolar tissue, nerve, or muscle be examined in any part of the body. I have dealt somewhat at length on this part of my subject because I think it well exemplifies those primary degenerative changes, so frequently witnessed in the pathological history of diseased changes, in the course of which no proof exists that the phenomena of inflammation play any part in the series of morbid conditions. This was insisted on, I believe, years ago, by Dr. Handfield Jones, and the support of this doctrine derived from fœtal pathology is not to be under-rated, seeing that we have the simplest conditions of things to deal with. There is an absence of the outcome of prolonged wear and tear of tissues, physiological or artificial; nothing, in fact, beyond an inherent tendency to decay, or power of development beyond a certain grade, so that in place of the indifferent embryonal elements passing through their various phases, and culminating in the highly differentiated nerve-cells and fibres, they give rise first to mucous, and secondly and lastly to fibrous tissue. They have lost the conditions for a typical termination, and have become abortive.

In the second specimen (that which is before you) there

is a *multum in parvo* of teratology. The cranio-spinal canal is absent. There is no trace of either brain or spinal cord. The roots of the spinal nerves are in many parts wanting, although the spinal ganglia and nerves are fully developed. There is a decided talipes calcaneus of both feet, and a flexor contraction of one finger. The umbilical cord is partly membranous, and the abdominal wall connected with it is undeveloped, allowing the viscera to protrude. I may pass over all except the last, but as this strikes the key-note of the pathology of a formidable surgical disease, viz., extroversion of the bladder, a word or two of explanation as to its bearing may be given. The mesoblast, or middle layer of the blastoderm, splits into what embryologists term the somatopleure, and splanchno-pleure, which, as their names denote, go respectively to form the abdomino-thoracic wall and the alimentary canal. The space between the two layers represents the pleuro-peritoneal cavity. Now, in extroversion of the bladder, the anterior abdominal wall in part, and the anterior wall of the bladder are absent, so that the posterior wall of the latter becomes prominent, being pushed forwards by the underlying viscera, and chiefly the small intestine. On this the orifices of the ureters may be seen. If in the present case, we suppose the arrest of development, instead of being confined to the region of the umbilicus, to have extended further down, so as to have involved the lower part of the allantois, and the re-entering angle between it and the abdominal wall, then the conditions for extroversion of the bladder would be established, for, as you know, the allantois is an outgrowth from the primary splanchnopleural cavity, or, in other words, both the primary alimentary canal and the allantois open into a common cloaca. Add to this the fact that the urinary bladder is developed from the lower part of the allantois, then if there be an arrest of development of the anterior abdominal wall, and the subjacent part of the allantois, you have only to include those changes that take place soon after birth, and the deformity in question is complete. These changes consist in the separation of the parts whose development has only advanced so as to form a thin membranous layer, and which parts are in direct continuity with the umbilical cord. In short, instead of the cord falling off as usual after ligature, it does so in conjunction with the part of the anterior wall of the abdomen below the umbilicus and the anterior part of the bladder. A line of demarcation forms between the living and necrosed parts, cicatrisation takes place ; Nature does her best to make amends for her blunder, but the bladder opens on to the surface of the body.

THE CAUSES AND COURSE OF DISEASES OF THE HEART, WITH SPECIAL REFERENCE TO PREVENTION AND TREATMENT. (*a*)

A Course of Lectures delivered at the WEST LONDON HOSPITAL.

By J. MILNER FOTHERGILL, M.D., M.R.C.P.,
Assistant Physician to the Hospital, and to the City of London Hospital for Diseases of the Chest, Victoria Park.

LECTURE IV.—THE NEUROSAL AND REFLEX AFFECTIONS OF THE HEART.

THE lecturer commenced by saying that several writers on heart disease had stated that whenever a patient, not informed of his condition by some medical man previously, came into a physician's consulting room complaining of his heart, usually the heart was not diseased. His experience corroborated this ; and of all patients suffering from neurosal affections of the heart medical men themselves were the most unsatisfactory patients. They knew enough of the subject to put the worst interpretation on their symptoms, and in a week or two relapsed into their previous condition of thinking themselves the subject of grave disease.

The neurosal affections of the heart are of various kinds, but palpitation, irregularity, and intermittency, were the three chief forms ; syncope scarcely being included. The vascular system is intimately bound up with the emotions as seen in the blush, for instance, which is not confined to the face, but extends over the body generally. Emotion affects the vascular system variously according to the form of emotion. Terror produces contraction of the peripheral arterioles ; joyous excitement, a full dilated pulse, with exalted action of the heart. A certain voluntary control of vascular excitement could be practised by some individuals, a fact noticed by poets and other writers. The heart's action even could be temporarily arrested by some few individuals. Pressure upon, or irritation of the vagus nerve would also produce temporary arrest of the heart.

In some persons the heart seems swung in so fine a balance that little causes will produce excited action of it, especially in women. For the proper comprehension of palpitation it was necessary to have definite ideas as to its causation : there being several forms as well as the neurosal. In the first place there was the form associated with the muscular inefficiency allied to the palpitation of effort, where an increase in the internal pressure on the heart walls excited a more powerful discharge of the cardiac ganglia and an energetic ventricular contraction. Such palpitation was very commonly seen in dilated hearts, where it was produced by slight effort. Here palpitation was an active symptom of debility. At other times it was induced by a sudden contraction of the peripheral arterioles causing a rise of blood pressure within the arteries, and thus by increasing the obstruction the ventricle had to overcome on systole, setting up the excited action known and felt as palpitation. This form was common with gouty persons, mostly women, and especially with them at or about the menopause. In this last form dilatation of the peripheral arterioles by nitrite of amyl was the best method of treatment. He then read a letter from a patient with chronic mitral insufficiency who suffered from palpitation, but never had it when he had a cold. The effects of a cold were to dilate the peripheral vessels, lower the blood pressure in the arteries, and thus under these circumstances the crippled heart never palpitated.

Of the truly neurosal forms of palpitation, there were two divisions—the reflex, and that which was a true neurosis of the cardiac ganglia, just as whooping-cough is a true neurosis of the respiratory centre. Both forms were chiefly seen in women. Thus reflex palpitation was often due to ovarian trouble, or to a displaced uterus ; in the latter case usually ceasing abruptly when the womb was replaced. Palpitation was often set up by waves of nerve-perturbations, which start at some distant point, just as the gusts of neuralgic pain under the heart in women were due to ovarian congestion in the bulk of cases. The heart had been placed by older physiologists as the seat of the emotions, and it was commonly disturbed by excitement in the reproductive organs, even by ordinary indulgence in the nuptial rite, and such was not rarely the explanation of disturbed cardiac action otherwise inexplicable. Such were the reflex disorders, but palpitation might be truly neurosal depending upon some excitement in the cardiac centres. Here the heart beats excitedly on the slightest cause ; indeed, the cause of some attacks of palpitation was undiscoverable. Two such patients, mother and daughter, were to be found in the out-patient department of the hospital. The mother had been practically cured by a long course of quinine and hydrobromic acid ; but the daughter's heart was very intractable to treatment. These hearts never yielded readily to treatment ; where there was also anæmia it was well to give bromide of potassium with the tincture of iron. In chorea and in Graves's disease, the action of the heart is often so violent that it seems as if it would shatter off the chest-walls over it. As to the question whether disease of the heart were on the increase

(*a*) Abstract of Lecture IV. (*concluding*).

or not, an affirmative answer must be given in the case of men. During the American Civil War Dr. Da Costa had seen and described a condition which he denominated "irritable heart" among the soldiers. Here there was an excitable condition, the number of beats—more on rising from the recumbent posture—was above the normal, long marches were not well borne, and usually the sufferers had to be invalided. The treatment of this condition varied with each case; in some, aconite was most serviceable, in others, digitalis. Such a condition was occasionally seen in England.

The next neurosal disturbance was one of rhythm, known as irregularity. Here there was not a distinct pause, but a halt, as if the heart rolled over and then went on again. It resembled, the lecturer said, the change in a horse's feet when cantering. Sometimes the beat immediately following this halt was increased in vigour. When this irregularity was increased by exertion, it usually indicated a dilated heart. It rarely occurred rhythmically, as was the case with intermittency—the next disturbance to be considered. We are indebted to B. W. Richardson for the right interpretation of this phenomenon as a merely nervous phenomenon. He had shown that it was often nothing more than a nervous disturbance due to fright, to depression, or to emotion. It had been noted in a child at birth, and observed in animals. As to its mechanism, it was due to a ventricular halt, the ventricle requiring a second auricular contraction to set up its systole. This he had corroborated by observations on animals. Nevertheless, even Dr. Richardson admitted it was most commonly found in old persons, and the lecturer agreed with Dr. Hayden and others that intermittency was commonly found with atheromatous arteries and a feeble heart. Its significance entirely depended upon the conditions along with which it was found. At times the intermission was due to a feeble ventricular contraction, the pulse wave so set up being unequal to reaching the radial artery. He agreed with Dr. Balfour that the slighter forms of intermittency readily yielded to treatment. Where the pause did not affect the arterial blood-pressure it was of no moment; but if it did, so that the brain faltered from a momentary loss of blood, then it became a malady. Intermittency of the pulse was often found along with palpitation in ladies, and often caused them great alarm by wakening them up suddenly out of sleep, the sensation of the heart stopping being very alarming. Closely allied to intermittency was the very slow action of the heart found in some persons, and even in some families. It was usually nothing more than a mere peculiarity, though persons had been rejected for military service on that account. The lecturer concluded by saying that, having noted an intermittent action of the heart, it was like discovering a murmur—it was much easier to find such signs than to appraise their significance. They might indicate organic change or be but a form of nervous mimicry of real disease.

MILK-FEVER. (a)

By ARTHUR V. MACAN, M.B., F.K.Q.C.P., &c.

Dr. Macan said that milk-fever had been recognised by practitioners of midwifery for centuries, and, nevertheless, its very existence has lately been called in question. He passed in review the various theories which had been held concerning it, from the time of Willis (1655) up to the present day, when it is very generally looked on as due to the constitutional disturbance preceding or accompanying the first secretion of the milk. By recent writers, however, it is very generally thought to be due to the pain and local inflammation caused by over-distension of the breasts, which local inflammation is known by the redness of the skin covering them, the pain on pressure, and the line of inflamed lymphatics which often reach from the breast to the axilla. This is the view held by Prof. Schroeder, who says that, though in ordinary cases the rise in temperature that accompanies the secretion of the milk does not exceed a few fifths of a degree (Fahr.), still, in some cases, the temperature may rise to 104° or 105° from over-distension and pain. He defends the use of the term "milk-fever" for this condition, but admits that it might be more correctly called *non-suppurative parenchymatous mastitis*. Prof. Winckel, of Dresden, objects to the expression "milk-fever" as quite unscientific, and as tending to perpetuate false views as to the pathology of the affection. For he thinks that if the temperature rises above 100·76° some pathological change is always present, whether in the breasts or in the genital organs. Very similar views are also held by M. Chantreuil, and Dr. Wilds Lynn, of Philadelphia.

Dr. Macan had himself made observations on over 400 puerperal women during the time he was assistant-physician to the Rotunda Hospital. In about 27 per cent. of these cases the rise in temperature during the whole time the woman was under observation did not exceed 1° (Fahr.), and in 46·5 per cent. the temperature never rose to fever height (100·4°. Wunderlich). In 32 cases, or a little over 7 per cent., in which the temperature did rise to fever height, the only cause that could be found for such a rise was a painful and distended condition of the breasts. In a few cases, however, the temperature was normal, or even subnormal, although the breasts were very much distended.

The diagnosis of so-called milk fever was, he thought, at first quite impossible. For while on the one hand, if the breasts were full and tense when the woman was first attacked with puerperal fever they might remain so for twenty-four hours or more; on the other, he thought that a slight attack of cellulitis, or ordinary surgical fever, did not in the least diminish the secretion.

The conclusions he arrived at were shortly these:—

1. That there is no rise in temperature necessarily accompanying the first secretion of the milk.

2. That pain and distension of the breasts may cause fever, but this fever differs greatly from that generally described as milk-fever, for it comes on somewhat later, and lasts somewhat longer.

3. That the pulse in these cases is often lower than the temperature would lead us to expect.

4. In cases of fever during the puerperal state the presence of full breasts is not sufficient justification for at once diagnosing the case as one of milk-fever.

He also thought that the affection ordinarily described as ephemera, weid, milliary fever, and the seven forms of hydrosis described by Blundell, were but various expressions of ordinary surgical fever, or of the many forms of septicæmia. This is very much the idea propounded by Dr. McClintock in his note to Smellie's chapter on "milk-fever," in which he says, "For my part, I believe that many of the cases of rigor followed by pyrexia, coming on about the third, fourth, or fifth day of child-bed, and which, from being unattended by any marked uterine pain or tenderness, are commonly described under the euphemistic name of weid, or milk-fever, are really not milk-fever at all, but have a septicæmic origin. Extreme distension of the breast may cause some headache and febrile disturbance; these cases are rare, but in my judgment they are the only proper examples of true milk-fever."

In conclusion, Dr. Macan drew attention to the theory propounded by Dr. Carpenter in his "Physiology"—viz., that milk-fever was partly due to the re-absorption of the sugar of the milk into the circulation. This idea was probably founded on the discovery by Blot, that the urine of pregnant and nursing women contained sugar. This has lately been shown by Hempel (*Archiv für Gynaekologie*, vol. viii., p. 312) to be due to the re-absorption of the sugar from the milk in the breasts, but in none of the cases given by him did this re-absorption cause fever. Dr. Macan was not, therefore, inclined to agree with Dr. Carpenter that milk-fever could be even partly put down to such a cause.

(a) Abstract of paper read at the Obstetrical Society of Dublin. The debate will be found at page 385.

ON ASTHMA.

By J. B. BERKART, M.D.,
Assistant Physician to the City of London Hospital for Diseases of the Chest.

DEFINITION, PATHOGENY, AND ETIOLOGY.

A. *Definition and Pathogeny*

THE intense and intermittent dyspnœa associated with asthma which, mainly on account of its fitful appearance and departure, and its seeming independence of structural lesions, has been hitherto attributed to a derangement of innervation, is in reality due to pathological changes of the lungs. It is a symptom, and as such accompanies the idiopathic forms of chronic bronchitis and emphysema, as well as those that complicate the various cardiac and pulmonary affections. The dyspnœa in connection with the latter evinces, in an almost unmistakable manner, its symptomatic character, so that only erroneous views as to the causes of its intermittency have led to the supposition of its primary nervous origin. As those views have been fully discussed before no further reference will be made to the numerous varieties of the symptomatic asthma described by writers. The case, however, is different with regard to the dyspnœal paroxysms that accompany the idiopathic forms of chronic bronchitis and emphysema. The anatomical changes peculiar to these affections are not only slow and latent in their progress, but even after their complete development they are so imperfectly accessible to diagnosis as to appear quite out of proportion to the intensity of their symptoms. Those asthmatic seizures are therefore always the most conspicuous, after a time even the sole indication of the pathological conditions that take place in the lungs; and hence they possess all the clinical importance of a substantive disease, and require a detailed account of their nature and origin.

That asthma is a mere symptom can readily be proved. The recognition of this important fact has greatly been impeded by the exclusive attention paid to the clinical features of the paroxysms, and by the persistent attempts to deduce from them alone the nature of the dyspnœa. There are, however, but few chronic affections which, at a given period of their existence, present symptoms in themselves so characteristic as to admit a safe inference as to their origin. Even in those cases where the morbid phenomena are directly traceable to organic lesions, it is requisite to refer to the history of the disease in order to recognise its pathology. No valid reason can, therefore, be adduced why this established mode of procedure should be departed from in respect to asthma; on the contrary, its adoption is the more necessary, since objective examination, which generally affords the most important information, proves here of no avail. Nor is it admissible to disregard altogether those circumstances which, although separated by time, yet precede and follow the dyspnœal seizures with a striking regularity. Insignificant as they may be singly, those antecedents and sequelæ throw light on each other by their mutual relation, and exhibit, as it were, the life-history of asthma.

1. *Constitution.*—It is a striking fact that constitutional defects appear to be invariably associated with asthma. The very appearance of the patients is characteristic in that respect. The great majority of them are stunted or ill-grown, while their pale and sallow skin, their atrophic muscles, and their dilated subcutaneous veins betray a state of general malnutrition. Moreover, the square and prominent forehead, the deformities of the spine, and the disproportionately large or abnormally narrow thorax—all these are evident traces of bygone rickets. Others, again, may, at first sight, be taken for healthy and robust subjects; yet many of them owe this favourable opinion to their tendency to obesity at an early period of life—a sign, if not of rickets in a special form, at any rate one of premature senescence. Now, experience has warranted the assumption that the nutrition of the internal organs corresponds to that of the bony and muscular systems, and that in those individuals constituted as just described, the lungs, above all, are deficient in power of resistance to, and of repair after, injuries.

2. *Previous Disease.*—With the exception of the comparatively rare instances in which the dyspnœa is produced by a foreign body in the air-passages, asthma generally gives fair warning of its approach. Those subject to the disease have, previous to the appearance of the typical paroxysms, suffered from an acute or chronic inflammation of the respiratory organ. Of the 223 cases collected by Hyde Salter, the original cause of asthma was not ascertained in 40; in the remaining 183 cases, the original causes are stated as follows:—

Chronic catarrh, colds, and catarrhal pneumonia complicating whooping-cough, measles, and typhoid fever	132
Apparently spontaneous	10
Inherited and constitutional	11
Climate and miasms	8
Hard work, anxiety, and over-exertion	6
Outbreak and disappearance of eczema	5
Small-pox driven in on the lungs	1
Liver complaint	1
Bilious fever	1
Weak stomach	1
Indigestion	1
Supper of meat, onions, and hard beer (*sic*)	1
Sudden soberness	1
Hay-making	1
Suffered in teething	1
Sudden cessation of menses	1
Running violently	1
Total	182

From these statistics, it appears that bronchitis and catarrhal pneumonia have preceded the dyspnœal seizures in 80 per cent. of all cases; and this proportion would be still greater, if it were permitted to exclude those etiological factors, which seem, as such, highly improbable. It is needless to add, that this great frequency is not mere matter of accident, but points to a certain relation between the events. What influence bronchitis and pneumonia have upon the origin of asthma, will be evident from their anatomical details. In 62 per cent. of those case the inflammation occurred in the first decade of life, and was either idiopathic or a complication of whooping-cough and measles. Now, in feeble, narrow-chested children, and in those affected with thoracic deformities more especially,—and these supply the greatest contingent of asthmatics,—bronchitis, though commencing in the larger, has the tendency to spread to, and even beyond, the smaller tubes. Under these circumstances, the bronchial wall is inundated with a gelatinous (synovia-like, Rokitansky) substance, consisting of serum and white blood-corpuscles. The same kind of exudation exists also in the interlobular tissue, and here diffuses itself so as to reach even the pleura. Some of the alveoli are inflamed; some are filled with aspired mucus; others are in a state of atelectasis; and, again, others are the seat of a vicarious emphysema. (*a*) It is true, these anatomical details are derived from fatal cases, and it is quite possible that they may differ in extent and intensity in surviving cases. The difference may be such as to allow a complete resolution, and with it a complete recovery, although, to all appearances, the constitutional disposition of the patients is by no means conducive to that favourable issue. Again, "colds" and bronchitis in the adult are elastic terms for very variable anatomical conditions. If a patient be affected with a slight cough, and if, what rarely happens, he should seek advice for it, the normal resonance of the thorax, and the presence or absence

(*a*) Ziemssen, "Pleuritis u. Pneumonie im Kindesalter." Berlin, 1862, p. 293 et seq.—Buhl, loc. cit., p. 112.

of "catarrhal" rhonchi, by no means prove that the inflammation is limited to the internal mucous layer of the bronchial lining. The subsequent course of innumerable cases of this kind plainly shows that the process commenced in the interlobular and peribronchial tissue, and thence gradually spread to the internal surface of the bronchi; yet, as that process neither diminishes the volume of air in the lungs, nor impedes its entrance and exit to and from them, the full extent of the disease cannot be recognised at its early stages. However this may be, there can be little doubt that if an individual—child or adult, who, up to a certain time enjoyed good health—be attacked with what seems to be a bronchial affection; that from this he apparently recovers, but remains henceforward subject to asthma; all this strongly argues that the respiratory organ has been permanently injured by the preceding inflammation. There yet remains a minority of instances in which asthma is apparently congenital or spontaneous. But the question is, how far, on the one hand, congenital atelectasis, and how far, on the other, those insidious interstitial changes of the pulmonary tissue are responsible for it. There is no means of determining when and how commences the process that ultimately leads to granular atrophy of the kidneys. And, undoubtedly, a closely analogous process takes place in the lungs. Moreover, many patients, suffering from what is called chronic bronchitis, are by no means precise in their statements as to its origin. They date the first commencement of their illness from their recent catarrhal attack, which has only aggravated their condition; ignoring altogether the cough, expectoration, and shortness of breath, to which they have gradually become inured during the slow development of their disease. (*a*)

3. *Sequelæ.*—Emphysema and bronchiectasis, the one preponderating over the other, as the case may be, soon appear in the train of asthma. The fact that a nutritive and a mechanical element concur to their production, deprives the theory that these affections are consequences of asthma, of all foundation. Eppinger (*b*) denies the nutritive disturbance of the pulmonary tissue, and endeavours to show that severe cough is the sole and exclusive cause of emphysema. Without entering, however, into a discussion of his view, it is enough to say, the origin and persistence of a severe cough in *perfectly healthy lungs* would be quite inconceivable. So far as asthma is concerned, there is evidence, already alluded to, that a predisposition inherent in the lungs is mainly instrumental in the causation of alveolar and bronchial dilatations. That predisposition, however, is apt to be overlooked; the changes peculiar to it pursue their course gradually and unperceived, and their existence is known only when their destructive work is completed.

Hence the antecedents and sequelæ of asthma manifest themselves by their nature, as *one continuous though protracted pathological process. Asthma, therefore, is only one link in a chain of quasi-independent affections, which commences with inflammatory changes of the pulmonary tissue, and terminates with emphysema or bronchiectasis.*

Thus, according to this definition, "the essential or idiopathic asthma" of writers corresponds to the dyspnœa accompanying the gradual and latent progress, and their "symptomatic or catarrhal" to the fully developed state of chronic bronchitis and emphysema. The various classifications of the disease that have been proposed are, for obvious reasons, inapplicable to the present case.

In view of the different sense in which asthma is here taken, the question arises whether it be advisable to retain the term with which the idea of a nervous disturbance has at all times been associated? There is, indeed, a certain suspicion that misconceptions as to the nature of those paroxysms may easily arise in this way. Yet asthma well expresses the clinical peculiarities of that form of dyspnœa, and may therefore be advantageously adopted for the purpose of description, without prejudice, however, to its pathology.

Clinical Records.

ON SOME CASES OF IMPERFORATED OR DEFICIENT BOWEL.

By Dr. G. DE GORREQUER GRIFFITH,
Senior Physician to the Hospital for Women and Children; Consulting Physician-Accoucheur to St. Saviour's Maternity.

I HAVE now had seven cases of this kind—four of which were saved by timely operation, and three died, in which it was too late for me to take any remedial action, or even entertain the smallest hope of remedy. The first infant was not brought to me till vitality had ceased in some parts of the body, and the appearances had become most deplorable; the bones, beneath the mummy-looking skin which folded around them loosely and baggily, were partially enclosed, not wholly so, for at those points where any unavoidable pressure existed, such as the sacrum, the elbows, and the back of the head, death of the integument had occurred, and sloughing had separated the dead from the tissues, which I can hardly speak of as living, so low was their vitality; the blackened, moist, gangrenous patches that, here and there, further defaced the body; the ulcerated and sloughing corneæ told, of how far death had been allowed to play with its prey before I was asked to strive to win back to life what might have been saved, but what was now scarcely a thing of life. I can hardly call it anything than a living death, or a decomposing life.

I was unable to get a *post mortem*, as the child was brought from the country to me and taken back the same day—to die.

The next fatal case was also brought, when death and decomposition had begun to seal up the avenues of life, and I declined to give my knife the opprobrium of endeavouring to open what I knew could not be unsealed, and of having only hastened the extinguishing of existence. In this case, life could readily have been preserved, had the attempt been made in time; for, as I found by *post mortem* inquiry the bowel terminated in a large expansion—just as a river runs into or from a lake—which might have easily been reached by pushing a curved trocar and canula through the rudimentary anus that acted as a landmark for the surgeon's guidance.

The third instance (*a*) I shall here cite more particularly:—

On Sunday evening, May 6, 1877, I was asked to see a child which had been born on the Friday previously, as no relief from the bowels had been obtained since birth, and it was considered something was wrong. I must mention that the medical attendant had previously examined, and finding the anus, as he considered, permeable to his little finger, had forced it onwards thinking he had entered the bowel. When I examined, my finger passed into what we must consider the representative of the anus in the perinæum, but I was quite satisfied I had not entered the rectum; and it occurred to me, that the medical attendant had passed his finger into a recto-sacral pouch—behind the bowel altogether—as indeed the dissection afterwards proved—which yielded all the more readily because of the absorption of the fat that had taken place since the birth, interval days, when the child had to feed, as it were, on itself, and in which consequently, tissue waste had rapidly taken place: it also occurred to me that the bowel, or what would represent it, might open into the bladder by an aperture too small to permit the exit of fæces, or else, in front of what seemed to be the rectum:

(*a*) Paper read at the Harveian Society.

taking this view, I determined to explore with a gum elastic catheter and endeavour to get it, if possible, into the true anus and bowel, and should this not be practicable, to then perform Amussat's operation for formation of artificial anus, if the child at all rallied. Death, however, soon occurred, after my visit.

Being permitted to examine the body, I practised Amussat's operation, and divided a cord-like substance which subsequent more minute examination showed me to be what represented the bowel; this lay just in front of, and below the left kidney, but behind and superficial to the distended, and greenish-black looking, intestine. I divided this structure, because I did not know what it was, and could not make out, and took this step partly to mark it, that I might afterwards recognise it, when the relation of the parts would be disturbed. After its division, the artificial anus was easily made.

I then laid open the abdomen with the usual mesial incision: the allantois was full of fluid, as was also the bladder; the uterus seemed large for such infant life, and was tilted completely back against the sacral promontory, being lifted out of the pelvis apparently by the distended bladder; the ovaries and Fallopian tubes were well developed.

The first thing that arrested attention on laying open the abdomen by the mesial incision was the quantity of peritoneal serous effusion; and next, the intestines, enormously inflated and quite green-black in hue; on more minute investigation, these were found to be the small intestines, their inflation and great distension continuing to the part where the peritonæum tacked them to the spine, the muscles intervening, and where one arch either of peritoneum, or of band of adhesion fastened them down very firmly, and evidently had occasioned the arrest in development at that point, and the subsequent blocking and shrivelling; following the cord-like folds which I show, I came on the division I had made, while practising the operation for artificial anus—and following on still further, I found that the bowel,—if we may so designate this worm-like structure—did not communicate with either the bladder or the vagina, but was continued to what represented the anus, which was itself not all perforated, the worm-like structure being occluded for its entire length by a thick cheese-like, or putty substance.

The catheter, as is here represented, has been passed—after the *post mortem* was completed—into the anal extremity of the worm-like, shrivelled bowel.

I need not say that even had I during life succeeded in reaching the true orifice of this shrivelled bowel, no good could have been effected, because, having so many coils of it to force, I could not possibly have dealt with it efficaciously, that is to say—have made an alimentary canal sufficient for life purposes; and the only operation for real good, would have been the lateral anus, but made sufficiently early, certainly before the fatal collapse ensued in which I first found the child. I have given what I deem to be the cause of this atrophic malformation; I would now ask what is this pappy, grumous-looking, material which fills the narrow passage, and blocks the way of ingress and egress?

The cases in which I operated successfully were four:

In two, the anus was occluded at its very outset, there being only an annulus, indicative of where it should be; in the other two, there was a continuation upwards, or depression, to the depth of about the length of the little finger-nail cut short; these depressions or sulci I followed up by a burrowing movement of the little finger, very little of the knife tip being required as a dissector, the handle of it, and the fingers, answering all purposes in one case, while in another, the finger alone sufficed, till I reached the bulging downwards which marked to me where to make the opening; here I held the finger tip, and having the abdomen of the infant pressed on by an assistant, a measure which greatly facilitates the operation: first, because of the direct pressure, and second, because it makes the child cry, and so increases the downward pressure, and expulsive force against the fingers—I guided a small trocar against the resisting membrane, penetrated the latter, withdrew the trocar, the canula remaining, allowing the fæces to flow away to make sure I had rightly perforated, pushed the canula a little farther in, withdrew it altogether and forced the tip of the little finger into the opening, dilating it, till the finger passed in and out, up and down, without any impediment. I then introduced a large sized catheter, leaving it in for a few minutes: after its removal, the diaper was fastened on, and the child given back to the parents.

Daily the opening was maintained by introducing the finger, till at length, every second or third day sufficed, and afterwards longer intervals were allowed. I did not even seek to draw down the bowel, so as to affix it to the anus, but left it *in situ*, where I had pierced and bored it: and from this plan I found good passages have resulted, becoming lined with, if not mucous membrane, a tissue which answers all fæcal and alimentary purposes, nor have I ever had any complaint of narrowing or closure. We must, therefore, conclude the operations to have been eminently successful.

THE NECKER HOSPITAL, PARIS.

Cystitis Treated by Instillation of Nitrate of Silver.

Under the care of Prof. GUYON.

(Reported by M. ALF. JEAN, Interne des Hôpitaux.) (*a*)

IN the service of Prof. Guyon there are often patients suffering from inflammation of the neck of the bladder. This affection, which has generally for its first cause blenorrhagia, shows itself either after intense muscular fatigue, or is the result of excess of *coitus*, or the abuse of alcoholic drinks. Many forms of treatment have been praised and employed by surgeons, into which it is not now necessary to enter.

For ten years Prof. Guyon has employed direct treatment of the inflamed neck by instillation of nitrate of silver. Unexpected results have proved the efficacy of this method, and from many successful cases we select two:—

CASE I.—*Cystitis of the Neck—Hœmaturia—Treatment by Instillation of Nitrate of Silver—Complete Cure in Seven Days.*

F. ———, æt. 38, admitted 9th January, 1878, to Salle Saint-Vincent. About ten years previously had suffered from long-standing blenorrhagia. In consequence of excess in drink and *coitus* about a month previously, the patient experienced difficulty in urinating and very acute pain at the time of micturition, especially towards the emission of the last drops. Blood soon appeared in urine; for a month at each discharge there was hæmaturia. He urinates frequently during the night, and during the day has pressing desire every five or six minutes.

On exploration of the canal, we find that an exploratory bougie, No. 16, passes easily, with a slight resistance in the bulbary region.

Jan. 9th.—Instillation of 20 drops of a solution of nitrate of silver in the neck of bladder.

10th.—Blood still in urine; the patient suffered for about two hours after injection, and made water about every quarter of an hour. During the day injection of 20 drops.

11th.—Amelioration; urine less clouded; injection repeated.

12th.—Urination less frequent, about every hour. Blood disappeared; in its place a muco-purulent discharge.

13th to 17th.—Same treatment; daily injection. Blood still absent, vesical distress. Micturition every two or three hours. The injection is much less painful. The patient is able to rise during the day.

17th to 21st.—May be considered cured. There is still

(*a*) *La France Médicale*, March 16, 1878.

a slight pricking at the end of micturition. Injection continued every day.

22nd.—Patient discharged perfectly cured.

He has been seen since that day, and his recovery has been definite.

CASE II.—*Blenorrhagic Cystitis—Cure in Eight Days.*

B ———, æt. 25, admitted 26th January, Salle St. Vincent. Three months previously he had suffered from blenorrhagia, which lasted a month; for six weeks experienced pricking towards the end of micturition; at the same time he was obliged to rise during the night to urinate; during the day the desire was more frequent.

About eight days previously, after some fatiguing work, hæmaturia appeared, the symptoms increased in severity, and in this condition he was admitted to hospital.

January 27th.—Urethra examined with olivary catheter. It is completely free, slight pain as the instrument entered the neck of the bladder. Urine contained a large quantity of blood. Injection of a solution of nitrate of silver.

28th.—No amelioration. Urine bloody. Injection repeated.

29th.—No amelioration. M. Guyon, *struck* by the persistence of the hæmaturia, injected himself 12 drops of a stronger solution, and found that the two former injections had been made not in the prostatic region of the urethra, but into the bladder, and hence the liquid by mixing with the urine had not exercised any local action.

30th.—Improvement; no blood in the night urine, a little in that passed in the morning. Micturition less frequent.

31st.—A little less blood; the pain after the injection is not so violent, and of shorter duration.

Feb. 1st to 5th.—Improvement. No injection.

6th.—Another injection. Urine continues free from blood.

7th to 8th.—Injections repeated.

9th.—Discharged cured.

Remarks.—The rapid and complete cure of the hæmaturia, and the disappearance of pain by the method of instillation, make these cases remarkable and worthy of interest. To perform the injection, a syringe is used somewhat similar to that of Pravez, to the extremity of which is fitted a catheter with an ordinary bulb perforated through its whole extent. After ascertaining that the canal of the urethra is free, an instrument sufficiently large is chosen, so that it may be easily felt in the scrotal and perineal region, and that it grates against the lateral lobes of the prostate.

The sensations perceived with this instrument will be as clear as if felt with the finger, and we have perfect knowledge of the region of the urethra it traverses. In the membranous region, the bulb will be slightly held by muscular contraction, then it will free itself in the prostatic region as long as it remains in this region. We know it by the slight pressure necessary for the instrument, and as soon as it has cleared the neck of the bladder the fingers will feel a sensation of absolute liberty, indicating the entrance of the catheter into the bladder.

It is especially in traversing the prostate we feel the benefit of a moderately large catheter; without this precaution we cannot feel the entrance of the instrument into the bladder, and the caustic is injected into the urine, as happened in the second case. Some authors advise measurement of the urethra, in order to recognise the exact point, but this system is defective.

In the two cases we have narrated the patient suffered pain one or two hours after the instillation, but the pain is not very severe, and becomes less intense after each injection. The duration of treatment is relatively short and effective, and when it fails we must attribute it to either pure inflammatory cystitis, or to the failure of the injection in reaching the locality inflamed.

Transactions of Societies.

DUBLIN OBSTETRICAL SOCIETY.

THE Society met on Saturday, March 9th, 1878, Dr. Darby, President in the chair. Dr. Macan read a paper on

MILK FEVER,

which will be found on page 381.

Dr. DENHAM would like Dr. Macan to give the meeting a more detailed account, if he could, in respect of the primipara in the labours referred to in his paper. In his experience, those labours of first children were, as a rule, much more severe, and attended with more serious symptoms than subsequent labours. It was very often difficult to say what the cause might be. In his opinion, the fever preceded rather than followed the formation of milk. He had seen the breasts very much distended, severe rigors, followed by a very marked increase of temperature, and where there was much of that, with increased quickness of pulse. In his experience, when they found that during the night the patient had had severe rigors, that there was a hot skin, thirst, and so on, and looked at the breasts, and found they were beginning to distend, it looked a very ugly business. But there was a very important distinction between that condition and the condition where they had a rigor, where they had flat breasts, although the rigor might be followed by a hot skin and hot breasts. That was one of the most important features—they should distinguish between fever going on in a case where there were full breasts, and a case where the breasts were flexed. He should have liked Dr. Macan to have informed them of the amount of fever in primipara and subsequent labours, and was sorry he had not touched upon the treatment pursued in his cases.

Dr. HENRY KENNEDY said the author of the paper had given the Society a very elaborate detail, and a very interesting one, of the cases and the views of the most distinguished writers on the subject. The point he had alluded to was the connection between milk fever and swelled leg. He (Dr. Kennedy) thought that that *prima facia* must be at once disavowed, and for the simple reason, as far as he understood, that milk fever occurred within one, two, or three days after the confinement, whereas swelled leg, if he mistook not, occurred two or three weeks afterwards as a general rule, so that he would at once say that there was no necessary connection whatever between milk fever occurring in a woman just after her delivery, and a swelled leg which occurred two or three weeks later. With reference to the discrepancy between the temperature and pulse, that went on in other affections, and if they had the temperature at 104°, and the pulse at 100 or 108—(and that, he thought, was the pulse alluded to by Dr. Macan) he (Dr. Kennedy) believed they were not justified in making anything of a practical import from it, because that went on in other diseases just as it did in milk fever. The difference in temperament between one individual and another was immense, and as regarded females, that was particularly the case. The slightest affection in any female at once ran up the temperature, sometimes to an extraordinary degree, and so it was in the other sex too. That difference of temperament they must never forget; nor must they forget their civilised habits, which must have a great influence on diseases, and the extent to which diseases ran. The formation of milk was sometimes ushered in by symptoms that were most alarming, and he thought when they compared that process going on in females with other processes, which they knew went on in females, and considered the question of temperament, then they had a great deal of explanation of the very elaborate paper with which Dr. Macan had favoured the Society.

Dr. M'SWINEY said that Dr. Macan's researches into the literature of the subject had been made plainly manifest by the elaborate paper which he had communicated to the Society. The fever, as it had been described by the author and by Dr. Denham, occurred with headache, thirst, and hot skin, preceded by a rigor, either after or before parturition, and these were universally recognised occurrences; but there was a difference in this respect—that some parturient women would, after three days or so, present a most completely formed breast of milk without it having been made manifest by any trouble on their own parts, or any complaint of any suffering or any inconvenience whatsoever. What was the explanation of that? Yet it was a positive fact, as many

gentlemen present, who had perhaps more experience than he had in the treatment of obstetric cases, knew.

The PRESIDENT said he had not unfrequently seen breasts overflowing with milk before parturition took place; but he saw a case, within the last few months, of an unmarried girl having had something like milk fever, which ended in abscess of the breast, and gave a great deal of trouble indeed. Her menses were regular, but she had tension of the breasts, and all the symptoms of the fever, and had she been recently confined, he would have said it was a case of milk fever.

Dr. MACAN, in reply, said that Dr. Denham's question as to the frequency of milk fever in primipara, depended upon the theory as to whether the fever was due to a physiological process taking place for the first time. The reason, according to Dr. Denham's theory, that milk fever was more common in primipara, was because the breasts were for the first time taking on the secretion of milk, an unusual process, and accompanied by fever. That, he (Dr. Macan) thought, was the essence of the argument. If then they came to the conclusion that there was no such thing necessarily accompanying this secretion, he thought they had got rid of the idea that it was necessarily more common in primipara than pluripara. No one reading the old books, and reading the many accounts given of milk fever, could doubt that such observers as they were saw the things which they described. It was not a question that the thing did not happen. Anyone who had been a month in a lying-in house knew that. The only point in the discussion was the explanation of the fever. He wished it to be perfectly understood that there was no question as to facts, they were patent to all. In the majority of cases the fever passed away—they found the woman well in three or four days. The only thing was the explanation of the cause of that fever. There were a great many causes, the most obvious being surgical fever, which corresponded, he might say, exactly to what was ordinarily known as milk fever, and that connected milk fever with rupture of the peritonæum. The most important point was that raised by Dr. Denham—as to whether or not the rigor preceded the secretion of the milk. He (Dr. Macan) thought if that was the case that it entirely excluded the idea of milk fever being dependent upon expansion of the breasts. What he wished to consider was—not that the fever was due to the secretion of the milk, but that it was due to the over-distension of the breasts. The difficulty of diagnosis was extremely great in the present day. That difficulty was, in his opinion, caused by pressing off the placenta. He thought that septicæmia and its connection with the pulse was very important. In a case of septic infection he thought they would find that the pulse sometimes went up to 160°—not that he looked upon that as anything at all except the septic infection. He thought the diagnosis of septic infection was dependent upon the pulse alone. He quite recognised that the mental condition had a great influence on the puerperal state. As to the temperature in menstruation, he had not much experience of. Wonderlicht said the temperature did not rise during menstruation. As far as the treatment of the affection was concerned, he (Dr. Macan) thought the best thing they could do was to leave it alone. John Hunter did so. As far as their treatment was concerned it was lately confined to doing nothing at all. In his opinion strapping of the breasts was the most efficacious mode in which the secretion of milk could be prevented. The diagnosis of milk fever was most difficult, and he therefore thought it was more prudent in the large majority of cases not to pronounce an opinion the first time the patient was seen.

The Society shortly afterwards adjourned.

Translations.

ON ANÆSTHESIA DURING LABOUR, AND ON LIGATURE OF THE CORD. (a)

THE employment of anæsthesia in natural labours is again occupying the attention of the medical public. Dr. Bailly, who published in the *Bulletin Thérapeutique* a communication on this controversial subject, is of opinion that, from a practical point of view, anæsthesia employed in natural labour marks a most important step in the progress of obstetrics.

(a) *La France Médicale*, Feb. 1878.

A partisan of the method inaugurated by Simpson (popularised in France by M. Campbell), M. Bailly advocates this therapeutical measure, as he has observed conclusive facts, as he believes, in its favour. Before describing the new apparatus of Legroux, some of the conclusions of Dr. Bailly are worthy of consideration. The contra-indications for anæsthesia, according to Dr. Bailly, in natural labour, are—

1st. The opposition of the patient to this mode of treatment.

2nd. Disease of the cardio-vascular system and the lungs.

3rd. The slight intensity of the pains.

It is indicated during the second period, during the time of expulsion, in patients who bear their pains badly; it should then be administered without waiting for the appearance of signs of exhaustion, as alteration of the features, dryness of the mouth, acceleration of the pulse, &c. Chloroform, he says, should be used at the beginning of the pain, or in the interval of uterine contraction, so as to produce not only calm, but drowsiness. This moderate dose may be continued for three or four hours.

The method of M. Bailly is not identical with that of M. Campbell. Anæsthesia employed by the latter is much more incomplete; he maintains that he is able, by means of very small doses, administered in an intermittent manner, to diminish the intensity of uterine contraction, to retard its return whilst the patient preserves intelligence and consciousness, so that the accouchement is completed in a state termed *lucid analgesia*. In a recent work on direct uterine narcosis M. Campbell has endeavoured to explain the mechanism by which these results, disputed by eminent opponents, are obtained.

In 1867 Dr. Fridet, in his thesis on the employment of chloroform, arrived at this conclusion: the degree of chloroformisation suitable for natural labour is that in which we have a light sleep—a semi-consciousness, as in a dream—and frequently a knowledge as to what is taking place around. The innocuity of Simpson's method is indisputable; it is demonstrated by facts, and depends, without doubt, as M. Bailly says, on the fact that in simple accouchements anæsthesia is not pushed so far as in surgical operations. The patient, far from dreading the operation of chloroformisation, likes it, as she knows it will alleviate her sufferings. We know the effect of chloroform in diminishing pain has been questioned, but we believe it is indisputable. The recent *mémoire* of Campbell on "Chloroform and Obstetrical Anæsthesia," proves that sensibility to pain diminishes before sensibility to temperature or contact. The analgesia obtained in obstetrical anæsthesia in small doses has been very justly compared to the effects produced when chloroform is administered in hepatis or nephritic colic.

One of the objections to the anæsthetic method arises from the difficulty of watching the labour, and at the same time administering the chloroform. M. Legroux, by modifying an apparatus designed by Demarquay, has produced a convenient one for chloroformisation. Its construction is simple, as may be seen from our description.

A small pyramidal mask of fine iron wire is covered with thick flannel. The chloroform is projected on the flannel in a very fine jet by means of a kind of *compte-goutte*, formed by a small graduated flask, into which a tube is fixed. This tube is bent at a right angle at its other extremity. The neck of the bottle containing the chloroform is armed with a caoutchouc ball, which, when compressed, exhausts the air, and effects the expulsion of the liquid through the tube.

This apparatus, as M. Legroux explains, allows the operator to graduate the quantity of chloroform administered to his patient, and as it is fixed on the head by means of lunettes it always remains in position, no matter how the patient may move.

M. Bailly says—"This instrument leaves nothing to be desired, and answers well the object for which it is intended. Without doubt, M. Legroux' apparatus will contribute to the popularisation of chloroformisation in simple labours, and will soon be employed by all partisans of the method.

Since the important work of M. Budin, on "Tardy Ligature of the Umbilical cord," a number of accoucheurs have examined the assertions put forward by the intelligent pupil of M. Tarnier. A recent article, by M. P. Helot, Professor of Obstetrics, Rouen, furnishes us with new details on the subject. In a short study on ligature of the cord M. Helot endeavours to fix the indications and contra-indications of the method already supported by Mauriceau, Denman, Leroy, and further established by the researches of M. Budin, who thus formulates his opinion:—"Ligature of the umbilical cord

should not be practised until one or two minutes after complete cessation of vascular pulsation." M. Budin concludes that we deprive the child of about 92 grammes of blood by immediate ligature. M. Helot publishes the statistics of MM. Brunon and Kohly, which also testify in favour of an increase in weight, and, from his own experiments, establishes the gain in blood, where tardy ligature has been adopted. The good effects of tardy ligature should be characterised by the coloura-tion of the skin, and an augmentation in weight, but the time for delay must be variable according to the cases, for M. Helot remarks that after the expulsion of the child the uterus contracts forcibly on the placenta, expelling the blood which it contains; it thus makes a kind of injection which theoretically in certain cases might become dangerous by exposing the newly-born child to plethoric complications.

FOREIGN DIPLOMAS IN GREAT BRITAIN.

There is, without doubt, an anomaly deserving of remedy in the existing prohibition to an interchange of the privileges of medical practice between foreign countries and ourselves. It is admittedly unreasonable that a fully qualified English physician and surgeon emigrating to (say) Brazil, becomes, on his landing there, a quack, until he has complied with a curriculum, and passed an examination infinitely inferior to those to which he has been already subjected; and it is equally ridiculous that a medical graduate of the best Continental universities on crossing the Channel should be forbidden the authority to treat disease in our own country. To say truth, there is no so great superiority in our own method of education or of qualification as to justify our refusal to admit foreign or colonial degrees to a position of equality. We are perfectly self-conscious that the practice of medicine and surgery is pursued daily in Great Britain and Ireland under the eye of the General Medical Council and its constituent colleges, and with their cognisance, by persons who are either half educated or not educated at all, and while this is so, we cannot with any reason ask Parliament to forbid the access of foreign or colonial graduates to reciprocity with ourselves.

All that Parliament has to consider is how it shall admit competent practitioners and exclude the incompetent, and—in the matter of foreign diplomas—this is an extremely difficult question, and one of which, despite the deliberations of the Medical Council and the thought given to it by the Duke of Richmond, no satisfactory solution has yet been obtained.

As regards the qualifications to practise granted in Great Britain and Ireland the public and the profession have done their best to protect the community against the depreciation of the educational standard. They have given to the Medical Council the right to visit and inspect examinations, to order what curriculum of education shall be accepted as sufficient, and, in case the examination and curriculum of any licensing body is insufficient to ensure the competency of its licentiate, they have authorised the Medical Council to exclude those licentiates from the legal practice of the profession. It is evident that these safeguards against low-class examinations, nominal education, and the sale of diplomas to unskilful and inexperienced persons, are inapplicable to foreign or colonial degrees. Visitation of the examinations of American or continental universities is practically impossible, for, though it might be feasible to inspect the examinations in the first instance, and as a preliminary to their recognition, it would be obviously out of the question to visit them with such frequency as to ensure that their stringency should be maintained. Then, again, it is plainly impracticable to suggest that the Medical Council shall supervise the education of foreign students, or it knows nothing, and can know little, respecting the educational value of the instruction given at continental or colonial schools of medicine. Lastly, even if it were possible to visit licensing bodies outside the kingdom with sufficient frequency and to make requisite a certain standard of education, these powers would be useless in the absence of any control over the licensing bodies in question. The Medical Council might—if adequately informed—refuse to recognise such qualifications in Great Britain, but it could not take upon itself to exclude any qualifying body upon the strength of such information as it might possess.

There is an admitted necessity to permit qualified foreign graduates to practise in Great Britain, not so much for the accommodation of aliens, who seek their medical fortune in our country, but to secure to our own countrymen the privilege of practising in continental watering-places, a privilege which was threatened to be extinguished in France, as a measure of retaliation for our refusal to admit foreign graduates to the medical register; and the Duke of Richmond attempts to meet that necessity by the following clauses of his Bill—

Clauses 5 and 6. "Where a person who is not a British subject (or, in the case of the colonies, is not domiciled in the United Kingdom), or who has practised medicine or surgery, or a branch of medicine or surgery, for more than ten years elsewhere than in the United Kingdom

shows that he obtained some recognised medical diploma, or diplomas as hereinafter defined, granted in a foreign country (or a British possession), and that he is of good character, such person shall, upon payment of the registration fee, be entitled without examination in the United Kingdom, to be registered as a foreign (or colonial) practitioner in the medical register.

7. "The medical diploma or diplomas . . which are to be deemed recognised, . . shall be such . . diplomas as may be recognised for the time being by the General Medical Council, as entitling the holder thereof to practise medicine or surgery in such possession or country, and as representing at the time of the grant thereof a degree of knowledge as tested by examination, equal to or greater than that which, at the same time, was required to obtain in the United Kingdom such qualification as entitles the holder to be registered."

It would seem that the registration of two classes of diploma-holders is here contemplated: firstly, the foreigner or colonist, who is an alien in the strict sense; secondly, the British subject who emigrates. Of these, the foreigner or colonist will be privileged to register his foreign diploma, and enter practice in Great Britain the moment he obtains it. The British subject, on the contrary, cannot apply his foreign diploma to a similar purpose, until he has practised ten years abroad. The intention of this restriction is, no doubt, to prevent British students taking a return ticket to Canada or Switzerland, and upon the strength of the diploma there obtained, setting up in practice in England, and, in this view, the restriction, though apparently unfair, is deserving of approval, not only because it will act as a protective to English colleges, but because it will prevent the inducement which would otherwise exist, to lower the British standard of education to a level of competition with America or Germany. Any enactment which excludes from practise that class of student who flies his own country to seek cheaper and easier diplomas elsewhere, should be welcomed by the profession.

In the 7th clause of the Duke of Richmond's Bill quoted above, the difficulty to which we have alluded presents itself in full force. The foreign or colonial diploma which is to be registrable is to "entitle the holder thereof to practise medicine or surgery in such possession or country."

There is, in the case of German degrees, very much more in this proviso than appears. In Germany the Government has taken all the important examinations out of the hands of the Universities and committed them to the care of separate Governmental boards. Whoever wants to go to the medical profession must first procure his "Abgangs Zeugniss," or University testimonial, and, on the strength of it, he may apply to be admitted to the "Staats Prüfung" or State examination, the university degree being insufficient to admit him to practice. Thus, it will be seen that, in admitting to the medical register such German degrees as "entitle the holder thereof to practise medicine" in his own country, we are receiving only the practitioner who has passed his "Staats Examen." We have the guarantee of the German Government as to his competency, as to his fitness, and that is a title to the public confidence very different from the degree of any University. Such a stamp of competency we may readily accept without question, and, therefore, in the case of German degrees, it becomes unnecessary for the Medical Council to take cognisance of the requirements of individual licensing bodies. This state of affairs is, unfortunately, not the condition elsewhere. In America, for example, the rights of practice differ in almost every one of the States of the Union. In some of them a degree of competency higher than our own is requisite for practice. In very many others, persons are allowed to practise on a nominal amount of knowledge, and the curricula and examinations are as various as possible. In some of the States a man may be "entitled to practise medicine or surgery" on the authority of an examination which is a mixture of allopathy, homœopathy, eclecticism, and numerous other forms of "pathys." It is difficult to understand the method by which the General Medical Council is to select amongst these, and to separate those diplomas "which represent a degree of knowledge, as tested by examination, equal to, or greater than, that which is required, to obtain in the United Kingdom such qualification as entitles the holder to be registered."

We trust that when the question whether a particular foreign degree does or does not "represent a degree of knowledge . . equal to or greater than that which is required to obtain" a British license, comes to be decided, a decision may be arrived at by some better means than that adopted by the General Medical Council for its recognition of certificates in preliminary education. In the published list of examinations accepted as sufficient evidence of general education, we find those of teaching bodies in Melbourne, Tasmania, and other places, respecting the sufficiency of which certificates the Council could have no knowledge at all. They seem to have admitted the *testimonium* of these teaching bodies to the recognised list, simply on the request of those bodies, and such other hearsay evidence as was accessible. Accordingly we find the Irish College of Surgeons refusing to comply with the suggestion made by the Medical Council, that it should abandon its own preliminary examinations, and refusing in the following terms:—

"The authorities of this College, from its foundation, have insisted upon satisfactory proof of sound preliminary knowledge on the part of candidates seeking their license, and with this object in view they long since established a court of special examiners, the members of which are selected solely with reference to their arts qualifications.

"In deference to the Medical Council, this Council has reluctantly accepted the certificates on preliminary education issued by other bodies than their own, the names of which appear to be approved of by the General Medical Council, but has done so with considerable hesitation, inasmuch as this Council cannot learn that the General Medical Council has ever taken efficient means to ascertain the character of such examinations. Whether the deficiencies in preliminary education evidenced by candidates at the several professional examinations are displayed by parties who have passed such boards this Council is not aware, but until assured of the efficient and searching character of such examinations, this Council cannot see their way to adopt the recommenda-

tion of the General Medical Council to the effect that this College should renounce its right to test candidates for its licence as to their preliminary knowledge by its own special board of examiners."

If the General Medical Council follows, in respect of foreign diplomas, the precedent created by itself in the matter of arts certificates, we apprehend the flooding of Great Britain with colonial licenses, obtained no one knows how. There is an attractive and lucrative field of practice in Great Britain, and there will be, therefore, a serious danger, in case of the passing of these clauses of the Duke of Richmond's Bill, that very many colonists and continentals who have become impatient of waiting for practice in their own countries will fetch their diplomas of doubtful character to Great Britain, and try their skill upon the public at our side of the water.

THE CAUSES OF INFANTILE SUMMER DIARRHŒA.

THE month of May reminds us that we are approaching that season of the year when the bills of mortality will be swollen by the ravages of infantile diarrhœa. And yet, notwithstanding this disease plays—every year and in every place—such an important part in the causation of infant mortality, espacially in all our large towns, the real causes of its great prevalence during the summer months have only lately been thoroughly investigated, and are even now but imperfectly known. Among the towns conspicuous for their high rate of mortality from infantile diarrhœa, Leicester holds the most conspicuous place. Indeed, the number of deaths which arise in that own from this cause alone have lately attracted much attention, and have induced the Government authorities, and more recently Dr. William Johnston, the Medical Officer of Health for Leicester, to make a more thorough investigation into the subject than has been hitherto made. Not that the town of Leicester has the reputation of being an unhealthy place in other respects. On the contrary, it holds a very favourable position in the tables of our annual mortality returns, while as respects the cleanliness and width of its streets, the free ventilation of its yards, and the general neatness of its artisan homes, it is, we are informed, unsurpassed by any large manufacturing towns in England. But there is no doubt about the excessive infantile mortality from diarrhœa, and it is interesting to contrast the position which Leicester takes in the general mortality returns during the winter months when diarrhœa does not prevail, with that which it holds during the summer months. Thus while in the annual rates of mortality per 1,000 for one week in August, 1877, in the 20 large English towns ranged in order from the lowest, Leicester is at the bottom of the list, its death-rate being as high as 33, as against Brighton, Sheffield, and several other towns whose death-rate was from 18 to 20. On the other hand, in a similar return for the second week in December, we find it at the head of the list for its general salubrity, its death-rate being only 17 per 1,000.

In the year 1875 the Sanitary Committee determined to make a thorough inquiry into the subject, and Drs. Buck and Franklin were appointed to conduct the investigation. They attributed the cause of the disease to "heat in conjunction with a water-logged soil." The land, they said, of the low-lying parts of the N.E. district of the town, where the concentration of the disease is most marked, consists of clay, of a bed of fine sand, and of artificial or made ground. In the N. and N.W. districts, the houses are built upon gravel, and here the deaths are scattered, as compared with those on the clay, and their specificity is not so marked. "The effect of heat, plus moisture, is well seen in the deaths about Lyttleton Street, where almost all the cases were of a specific nature, and where the soil was very damp," when they visited the neighbourhood. There are, however, as Dr. Johnston has shown in his able and laborious report, many facts which throw doubt upon the truth of the conclusion which Drs. Buck and Franklin drew from their inquiries. In the year 1868 the mortality from the disease amongst a population of only 90,000 was greater than has ever—either before or since—been recorded. In that year very high temperatures prevailed; when the rain first appeared (August 6th) the height of the epidemic had already passed. The rainfall of the 6th, 18th, and 22nd August was large, and on its appearance a marked diminution took place in the mortality, a diminution which was not interrupted by the high degrees of heat experienced during the first days of September. Indeed, during that year not only an almost unprecedented degree of heat was experienced, which lasted for over three months, but the rainfall from May 1st to August 6th only amounted to three-quarters of an inch. This fact is alone sufficient to discredit the theory above given, for here, in a year unparalleled for its high mortality from diarrhœa, a totally opposite condition to that of waterlogging existed, for the soil was everywhere parched, dry, and arid, through the long-continued drought and intense heat experienced.

That solar heat is the chief agent in generating summer diarrhœa in general, is universally admitted, the chief question being whether it acts alone or in conjunction with some other agent peculiar to the locality in which the disease is prevalent. With regard to Leicester, it is evident we must look for some other cause than that of the nature of its soil, and accordingly, Dr. Johnston, after an elaborate inquiry into the subject, comes to the conclusion that the summer diarrhœa of that town "is dependent upon the pollution of the air by the escape of sewage gas from the hastily devised, badly constructed, non-ventilated system of sewers." The grounds on which he arrives at this conclusion are: That diarrhœa has been proved by Drs. Murchison, Cameron, Thorne, Carpenter, and others to have arisen from inhaling air that is infected with sewer emanations, and that the distribution of the disease in Leicester corresponded more or less with the presence of faulty sewers, and with those localities where, owing to the structural defects in the sewers, the sub-soil is most polluted with sewerage matter, and the atmosphere most vitiated by the escape of gases from them. It appears that very few of the sewers laid down in Leicester are, from their flat gradients, self-cleansing. The whole system of sewerage is of insufficient capacity to meet the daily requirements of the town; and as a result of this the main outfall sewer,

and the main sewer connected with it, are running full during the day. Moreover, little or no means of ventilation exist for the sewers in the greater part of the town. Under such conditions, remarks Dr. Johnston, of non-ventilation and insufficiency, the gases are completely pent up in the sewers, where they soon attain high degrees of tension, and under which they escape into the surrounding sub-soil and outer air.

It is highly probable that, in many instances, and in the case of Leicester more especially, the mortality from infantile diarrhœa is increased by the contamination of the air with sewage gases; and this is the more likely when the disease assumes almost a specific type, and if, with the officer of health for Leicester, we regard the summer diarrhœa of that town as a disease of similar origin and closely allied in its nature to typhoid fever. From the facts above mentioned there is every reason to believe that the explanation given by Dr. Johnston is the right one, but not until we have had the crucial test of the drainage of towns having been made more perfect with a corresponding fall in the death-rate from infantile diarrhœa, can we say that the real cause of the unusual prevalence of the disease in Leicester has been proved to be the imperfect state of its drainage. One hundred and sixty-six cases of diarrhœa were registered in the Borough of Leicester during the three months ending September 30th, 1877. Of these as many as 130 were infants under 12 months, 20 were from 12 months to 2 years, and only 3 from 2 to 5 years. Again, with regard to the sanitary condition of the premises where the deaths occurred, 132 or 85·7 per cent. are reported in good condition, having open and well scavenged yards attached; and as to water supply, 117 or 75·9 per cent. of the houses were supplied with water-works water; nor must it be forgotten that little more than half (58·4 per cent.) of those young infants were suckled, 19 per cent. of them were bottle-fed, and 22 per cent. fed upon a mixed diet. Now it seems strange that a diarrhœa of specific nature should in a very large majority of the cases have been confined to infants under 12 months; infants, half of whom could not have been exposed to the disease through drinking impure water, whose parents were living in premises the sanitary condition of which is said to have been pretty good, half of whom were brought up by hand, improperly fed, and no doubt subject to other conditions, which, when combined with the prevalence of very hot weather, might, independently of breathing air contaminated with sewage exhalations, well account for so many of them being carried off by diarrhœa. At all events, even supposing that the cause insisted upon by Dr. Johnston has been in operation with respect to Leicester, it does not follow that either in that town or elsewhere is infantile summer diarrhœa, to be generally speaking, viewed as an effect of defective drainage and of the causes which give rise to typhoid fever in the adult. Diarrhœa is after all only a symptom, or if we call it a disease, we must admit there are several varieties of it—the diarrhœa of simple irritation, from improper food, &c.; inflammatory diarrhœa from catching cold, and the sudden suppression of the functions of the skin, bilious diarrhœa, &c. Indeed, there can be no doubt that intense solar heat is in itself a powerful factor in the production of infantile summer diarrhœa. Heat alone will kill just as cold alone will kill, and we generally find that the rates of mortality are very high when either intense and prolonged heat in the summer, or cold in the winter, is prevalent. Into the *modus operandi* of this solar heat we cannot now enter, but there can be no doubt that, were it allowed to exert its full influence, the rate of mortality from diarrhœa would continue in the best constructed and best drained towns in the universe. Fortunately, however, it is one of those causes against which we are not wholly unprotected; and what with suitable diet, suitable clothing, avoidance of the direct rays of the sun, and the occasional use of the tepid or cold water effusion, we may ward off or mitigate attacks of infantile summer diarrhœa.

Notes on Current Topics.

The Army Medical Department.

We have already noted the reply given by the Irish College of Surgeons and the University of Dublin to the inquiry of the War Secretary as to the causes of the abstention of students from entering the Queen's Service. The following is the answer returned by the Irish College of Physicians:—

Dublin, April 5th, 1878.

Sir,—I have the honour to inform you that this College has given the fullest and most careful consideration to the subject of your communication of the 21st ultimo, in which you ask, on behalf of the Secretary of State for War, the unreserved opinion of the King and Queen's College of Physicians in Ireland, as to the specific causes which render the Army Medical Department unpopular among medical students, and which produce the existing difficulty in obtaining candidates for the service.

I have further to inform you that this College has, at all times, taken the deepest interest in the medical department of Her Majesty's Army, as well on the general grounds of the relation it bears to the medical profession at large, as because so many of their licentiates serve in the department. The College would, at the same time, respectfully remind the Right Honourable the Secretary of State for War, that, on several occasions, they have expressed their views on matters connected with the department, both as regards the grievances which, in the opinion of the College, the medical officers have been subjected to by the issue of Royal Warrants and Army Circulars, revoking and altering the Royal Warrants of 1858 and 1873, and as regards the disastrous consequences which must necessarily ensue from a persistence in such a course.

In particular, the College would call the attention of the Secretary for War to a Memorial which they forwarded on 20th April, 1877, to the Right Honourable Gathorne Hardy, and which was prepared by the College in consequence of the issue of the Royal Warrant of 1876 and the Army Circulars of 1877. A copy of this Memorial the College beg herewith again to submit for the consideration of the Secretary of State for War.

The opportunity which your letter of 21st ultimo has afforded the College of their unreserved opinions being taken into the consideration of the Secretary for War, the College gladly avail themselves of, and in reply to your queries, they would earnestly but respectfully urge the following, as being, in their opinion, severally and collectively, the specific causes which make the Army Medical Service so unpopular among medical students, and which tend most materially to deter candidates from coming forward to compete for the vacancies in the department, viz.:—

1. The recent short service system, by which a medical

officer is liable to compulsory retirement at the end of ten years' service.

2. The abolition of the regimental system.

3. The disadvantage at which the medical officer is placed with respect to *sick* and *ordinary* leave, as compared with other officers.

4. The feeling of distrust produced by the frequent changes in Warrants and Regulations has caused a reluctance on the part of students of the highest class to enter a service in which they were unable to calculate with certainty on their future career and treatment.

I have the honour to be, Sir,
Your obedient servant,
J. Magee Finny, M.D.,
Registrar.

To Ralph Thompson, Esq., C.B., Assistant Under-Secretary of State for War.

A Renal Form of Typhoid Fever.

Dr. Charles Amat, in a thesis, describes a form of typhoid in which the renal symptoms are marked and characteristic. We have already descriptions of typhoid as it appears under a cerebral, cerebro-spinal, and thoracic form.

Dr. Amat draws the following conclusions :—

1st. The typhoid poison attacks the kidneys in the same way as the other organs—the brain and lungs, &c.; hence the necessity of admitting a renal form.

2nd. Recognised by M. Gubler, M. Al. Robin, and Hardy, this form has not yet been the subject of a complete description.

3rd. It possesses a complete symptomatology—slight diarrhœa, considerable debility, extreme adynæmia, earthy colour of skin, abundant epistaxis, rapid delirium, very high temperature, rash not abundant, and a special urological group of symptoms—sanguinolent colouration, odour of boiled bread, contains sediment formed by the red and white globules ; albumen in large quantities.

4th. The ordinary form differs from the renal form by the greater intensity of the abdominal phenomena, by the more abundant diarrhœa, by the delirium, by the less elevated temperature, by a more confluent eruption. The urine is orange coloured ; the sediments are not constant, consisting principally of urates and phosphates. The albumen is temporary.

5th. The kidneys present the signs of interstitial nephritis.

6th. The renal form may be confounded with the ordinary form, or with primary renal disease.

7th. The progress and duration vary. The termination is generally fatal.

8th. The variations in quantity and composition of urine aggravate the prognosis or render it favourable.

9th. The patient should be placed on milk diet, and cold baths are contra-indicated.

Antiseptic Precautions in Midwifery Practice.

In the April number of the *Obstetrical Journal* there is a paper on this subject by Dr. F. W. Newcombe, who thinks that the antiseptic precautions which are now so universally practised in the case of surgical operations should also be carried out in midwifery practice. When, he says, we consider that an operation is now seldom performed without carefully excluding the access of air to the wound, without surgeons, nurses, &c., carefully disinfecting their hands in carbolic solution, is it not just that the lying-in woman should have the same immunity from danger accorded to her, and the risk removed of septic poisoning? Dr. Newcombe would in many cases have the room disinfected, all superfluous furniture, carpets, woollen articles, &c., removed ; blankets, sheets, &c., thoroughly disinfected ; the diapers (which should be new) thoroughly steeped in a solution of carbolic acid and dried ; and a few sponges kept in a jar filled with a solution of carbolic acid. Care should be taken that no sewer gas can permeate the apartment from the proximity of a sink or water-closet. A bottle of carbolic acid should be provided, and the surgeon should lubricate his whole hand every time he examines a patient ; and if forceps or other instruments are used, they should be previously placed in a solution of this acid.

We do not, however, regard, as Dr. Newcombe does, parturition in the same light as a surgical operation, and, at all events, we think that such precautions as those above noticed will be generally found both unnecessary and impracticable. Besides, we doubt whether so much attention to disinfection, and so much fussy preparation would dispose the lying-in woman to that calm, hopeful, and confiding state of mind which it is so desirable for her to enjoy in the hour of her great trial. Under exceptional circumstances, these precautions should be certainly taken. but in ordinary cases we maintain that they would be found more troublesome than useful.

The Dublin Death-rate and the Small-pox.

The mortality of Dublin has risen still higher. For the week ending April 27 it was 34·0 per 1,000 of the population, that of London being 24·2, of Glasgow 25·4, and of Edinburgh 23·2. The health of Dublin thus appears to be 25 per cent. worse than that of the most unhealthy English towns. In the same week the deaths from zymotics had risen by 15 from the previous week, and exceeded the average of 10 years by 19. The deaths from these causes comprise 21 from small-pox, 10 from fever (2 typhus, 6 typhoid, and 2 simple continued fever), 12 from whooping-cough, 3 from scarlet fever, 2 from croup, 1 each from measles, diarrhœa, &c. The deaths from small-pox during the last seven weeks have been respectively 7, 12, 7, 10, 15, 9, and 21. Of the 21 deaths from this disease registered last week, 7 are chargeable to Meath Street district, 7 to Peter Street district, 3 to the other two South City districts, 2 to the North City districts, 1 to Donnybrook district, and 1 was a case admitted to hospital from without the Dublin registration area. Compared with the preceding week there has been a considerable decline in the admission to the six principal city hospitals, of persons suffering from small-pox, the number for the week being 70, against 110 the preceding week ; there were 196 cases under treatment in those institutions on Saturday last—20 patients died, during the week, and 57 were discharged as cured. Hospitals for the reception of small-pox patients have been opened in connection with the North and South Dublin Union Workhouses.

Volunteer Surgeons and the Crisis.

Surgeon-General Munro has issued a circular to the volunteer surgeons of Great Britain asking whether they would be willing to undertake local professional duty under the supervision of the Director-General, Army Medical Department; such duty not to interfere with private practice.

We should imagine that there can be only one response to this question, in an unanimous and patriotic affirmation. In the presence of a great national crisis it should be the duty of every citizen to support the Government, even though politically their policy may be deemed unwise, and as surgeons are a necessity, and the supply does not equal the demand—setting aside army medical grievances for the time—every volunteer surgeon should respond to the call, and thus provide for possible emergencies.

There may not be war, the services of volunteer surgeons may not be required, but the offer of services will be none the less appreciated. The volunteer ambulance movement may be reckoned already a great success, and when extended to the provinces will be still more productive of advantage in case of war, as a supply of trained bearers and assistants will thus be secured. The extension of the volunteer medical department, under the direction of the Director-General of the Army Medical Department, will place our military medical system on a sound and comprehensive basis, and will thus enable us to compare with the medical organisation of any continental power.

A Case of Cerebral Localisation.

The following fact, which came under the observation of M. Dumontpallier, is (says *La Presse Médicale*) interesting from the manner in which the symptoms observed during life were connected with the anatomical lesions found after death. It also demonstrates, as shown by the researches of MM. Charcot and Pitre, that the cortical motor centres for the two upper extremities are situated in the paracentral lobule, and in the two upper thirds of the ascending convolutions, and that the centres for the movement of the lower part of the face are located in the lower half of the ascending convolutions close to the fissure of Sylvius.

An old woman, 77 years of age, was admitted 12th March, 1877, into the hospital under the care of M. Dumontpallier. Her body is immovable, and completely relaxed. She opens and closes her eyes easily. There is no distortion of the features, no deviation of the tongue, and no facial paralysis. On the right side there is complete hemiplegia, and on the same side anæsthesia is equally complete. The left side is in a relaxed state, but at certain times the patient moves her left arm and leg. Sensibility is completely lost, or at least the patient is insible to either pricking or the application of cold. She seems to understand what is said to her, mumbles, puts her tongue out, but cannot speak. In spite of her advanced age, this woman perfectly recovered, when on the 5th of April she succumbed to an attack of pneumonia. The following appearances were found in the brain. On the surface of the left cerebral hemisphere there was a well-defined patch of softening, occupying externally the upper part of the ascending parietal frontal convolution to the extent of about 2½ centimètres, and internally the whole of the paracentral lobule. There was no discoloration, or anything to point to the occurrence of hæmorrhage. The softening was probably the consequence of a thrombosis or embolism; the great central ganglia, as well as other parts of the brain, were perfectly sound.

Indian Opinions on the Army Medical Department.

The *Pioneer*, an able and influential Indian paper writing on this subject, says:—The report now current as to an amalgamation of the home and the Indian medical services has had its effect on the hitherto popular Indian Medical Department; and instead of the usual crowd of applicants, the competition was limited to thirty men for twenty-five appointments; in fact, for the first time there was no competition worthy of the name. The idea of the authorities seems to have been to get men in for the army by the influence of the Indian service amalgamated with it; but the effect has been, instead, to drive men away from the latter; without attracting more candidates for the former. The short-sightedness with which the authorities have treated the medical officers of the army is now bearing fruit; and until the just grievances of those in the service are righted, there is no use expecting young men to come forward." Speaking of the steps that ought to be taken our contemporary observes:—"The ten years' service system is a monstrous error; it is now found that the bonus of £1,000 at the end of it does not even tempt the younger members of the profession. Restore long service, form medical messes at the larger stations, give back forage to surgeons-major entitled to it under the warrant of 1858, improve the uniform (a minor but still important point), and give some natural promotion by inducing the senior surgeons-major to retire, in the same way that the Indian and Royal Artillery field officers have been induced to go—viz., by improved pensions and bonuses—and then no doubt the service would be restored to a healthy condition.

Sanitation and Public Prejudice.

In an able report on the health of the Sidmouth Urban Sanitary Authority, Dr. Thomas H. S. Pullin gives some graphic illustrations of the prejudice and carelessness that sanitary officers have frequently to contend with. The *Sidmouth Journal* says "that if you want to damage a place and mar its reputation, the best thing to do is to appoint a medical officer of health." A sanitary official remarked last summer that "there was too much fuss made about sanitary matters now-a-days, and he did not believe that drains or water had anything to do with sickness." Another even went so far as to say to Dr. Pullin that he "wondered that a judgment didn't fall on the doctors for thinking they could prevent diseases that God sent!" At the last meeting of the Board, Dr. Pullin occasioned much surprise, and was widely censured, for suggesting that a chronic escape of sewer gas into a house where four deaths from scarlet fever, whooping-cough, and erysipelas not long since occurred, had exerted a deleterious influence on those deaths. There are several other facts mentioned in this excellent report of the Medical Officer of Health for Sidmouth, but our limited

space will only admit of our drawing attention to the ignorance, superstition, and prejudice that exist in some quarters on the subject of sanitation.

Treatment of Carbuncle.

CARBUNCLE is one of those diseases with regard to the treatment of which there is great difference of opinion. Thus there is the method of compression ably advocated by the late Mr. O'Ferrall, and more recently by Mr. M. H. Collis. There is the old plan of making a crucial incision, the more recent method of treatment by caustics. One surgeon relies chiefly upon poulticing; another upon punctures, followed by compression. Mr. Montgomery A. Ward, in a report on Practical Surgery (*Dublin Journal of Medical Science*, No. lxix., 1877), remarks that, in his opinion, compression is hardly practicable for large carbuncles situated on the back of the head: that in some cases the crucial incision is apt to be attended by hæmorrhage and a large suppurating sore, and that the use of caustics is often followed by a large cicatrix, a result which it is of great importance to avoid. The plan he has successfully practised is to make an incision from one-and-a-half to two inches long over the centre of the carbuncle when the slough has formed, and from four to six smaller counter openings round the central one. These openings are then plugged with strips of lint steeped in some stimulating application; the whole is covered with a poultice, and the carbuncle dressed every day until the sloughs have separated. The advantages Mr. Ward claims for this method are: That all the integument is preserved; that it has all the advantages, and none of the disadvantages, of the crucial incision; that there is almost entire freedom from hæmorrhage; that the occurrence of a large suppurating sore is avoided; that sufficient space is afforded for the escape and removal of dead cellular tissue; and that very slight cicatricial marking results.

Rectal Alimentation.

PROF. AUSTIN FLINT, the eminent American physician, cites (*American Practitioner*, Jan. 1878) some cases which show the tolerance with which the rectum receives nutritive enemata, and for what a length of time the system may be supported by this means. In one case rectal alimentation was wholly relied upon for fifteen months, and to a great extent for five years afterwards. In three cases it was practised for a shorter period, but with equally successful results. This plan of treatment is indicated in disease of the œsophagus, or of the cardiac or pyloric extremity of the stomach, in gastric ulcer, hæmatemosis, and acute gastritis, in "a peculiar affection of the stomach occasionally met with in young women and characterised by great intolerance of food, in those cases of invincible anorexia occurring in middle or advanced life, which probably depend upon degeneration of the gastro-intestinal tubules, and where, owing to blunted mental perceptions, or to coma, an inadequate amount of food cannot be introduced into the stomach." This treatment might also be resorted to in certain cases of vomiting during pregnancy, in which the patient's strength is much reduced, or even her life imperilled by want of nourishment. Prof. Flint does not think with Leube that milk, eggs, and meat-broths are unsuited to rectal alimentation; for he has found that the rectum digests and assimilates these articles without difficulty, especially if a little pepsin, pancreatin, or hydrochloric acid be mixed with them. The injections, which should vary in amount from three to six ounces, may often be introduced into the colon by means of a flexible tube.

The other Cinchona Bases Compared with Quinia.

DR. W. K. NEWTON (*Medical Record* of New York), from a review of the evidence upon the subject, and from his own experience, comes to the following conclusions:—

Quinidia sulphate, when chemically pure, is almost a duplicate of quinia, and may be given in the same doses; it does not cause any more gastric troubles than quinia; even the commercial salt is as efficacious as quinia. Cinchonidia sulphate is also closely allied to quinia in its effects, and may be given in the same doses; but it is more apt to cause nausea and vomiting, and even purging, than quinia or quinidia. This salt is not recommended in diseases of the genito-urinary system, or after operations on this tract; neither is it to be given when shock exists. Cinchonia sulphate is a valuable anti-periodic, but must be given in larger dose than the other salts. It is quite apt to produce gastric disturbances and cause purging. Thus it may be seen that the three alkaloids may be substituted for quinia, but that quinidia and cinchonidia are better substitutes for that salt.

The question does not interest the city practitioner from an economic point of view, but it is one of importance to charitable institutions and to the country practitioners who furnish patients with medicines, and who buy in large quantities.

Plague of Flies in County Derry.

THE local papers report that the people of several districts in county Derry are at present suffering under a painful visitation of a species of fly hitherto unknown in that county. It made its appearance in numbers so vast that the air is filled and obscured as with a mist. Horses, cattle, and men are indiscriminately attacked, and with the most painful results. The insects fill the ears and swarm round the eyes of horses and cattle. Their sting is most venomous, and produces inflammation; and farmers find the greatest difficulty in working their horses, as the eyes of the animals are sometimes closed from the pain produced by the insects. Cattle cannot remain in the fields, but rush wildly home in terror and agony, and the people themselves are attacked on hands, neck, and face, and can only ward off the stinging assault by means of extemporised fans of some kind.

Royal College of Surgeons in Ireland.

THE annual election of examiners occurs next Tuesday, and the present officers, and, in addition, Messrs. Wheeler and Robinson, are candidates. The former gentleman has resigned his seat on the Council, and as on this body there may be other vacancies, it is expected that several candidates may come forward. Dr. Jacob and Mr. Elliott have already announced their intention to do so. The vice-president, Mr. Smyly, will be advanced to the chair, and will be, it is believed, succeeded by Professor Mapother.

A Dangerous Cosmetic.

To be swindled into giving £200 for a few bottles of dirty water is, it would seem, not the only or the worst risk which vain and feather-headed women of fashion run in their pursuit of admiration. The use of lead lotions for hair washes, and of arsenical pigments for the skin, have been long since known and exposed, yet the use of these "hair restorers" is persisted in with as little consideration as if they were noted for their healthiness.

In the *Analyst* for April Mr. Charles Piesse says that he had submitted to him for analysis a small quantity of a white substance, in the condition of a magma, and he was informed in reference to it that it was used by an American lady as a face cosmetic. The lady, unable to purchase the preparation in London, desired to have some manufactured especially. The result of his examination showed that the substance consisted wholly of *calomel*, the wetness of the magma being due simply to water.

The existence of such a cosmetic in the American market is another instance of the 'cuteness of the Yankee,—regardless of consequences.

Anthropology at the French Exhibition.

One of the most interesting features of the present Exhibition is, certainly, the Museum of Anthropological Sciences, organised by the Anthropological Society of Paris. A part of the gallery surrounding the central dome of the palace on the Trocadero has been placed at the disposal of the society. The Commision, to which the organisation has been entrusted, is composed of eminent men, including Messrs. Quatrefages, Broca, de Mortillet, Topinard, Bertillon, Barbier, Horelacque, &c., and they have formed local committees in Austria, Russia, Sweden, and Spain. There are already enrolled 140 exhibitors, amongst whom are the owners of 16 museums. Of these, one of the most interesting is the Museum of Paperswyl, belonging to Count Plater, it is noted for its ethnographic and archæological riches having reference to Poland before its dismemberment.

Poisoning by Potassium Chloride.

In the American *Journal of Pharmacy* Mr. G. W. Kennedy details the case of a child which had eaten about half an ounce of the salt, in consequence of which violent vomiting set in after some time, producing gastritis, collapse, and death seven hours after the salt had been taken. A peculiar symptom observed was the strong inclination of the child to slumber, it being in a lethargic condition from the time it was first noticed until it expired.

A Novel Milk Adulteration.

To the *Analyst* for April Dr. J. Muter communicates the result of examination by him of a sample of milk to which his special attention had been directed, in consequence of the very low percentage of ash which his preliminary analysis showed.

After numerous researches, he at last found that the foreign matter in the milk was glycerine, which is certainly a most ingenious addition, as a solution of that body in water of 12 per cent. strength has a specific gravity of 1.030; and he found, after several experiments, that 35 per cent. of such glycerine water might be added to milk without being detectable either by gravity or by the ordinary "solids not fat" process. Moreover, such an amount does not give any extraordinary sweetness easily detectable by the taste.

Effect of the War on Insurance Premiums.

The appeal of the insurance companies to the Austrian Govrenment to obtain a satisfactory disinfection of the fields of the late battles in Bulgaria and Roumelia, is an instance of the singular complications of modern society. A number of dead bodies lie unburied in Turkey, and an epidemic is dreaded in Vienna, which may seriously affect the calculations in the actuaries' tables. Apprehension is certainly not unreasonable; the frightful form of typhus which is now raging in South-Eastern Europe and in Armenia may well make the directors of insurance offices uneasy, to say nothing of the insurers themselves, who have probably hitherto given little thought to the matter.

Absorption of Tincture of Iodine by the Skin.

Dr. L. Menager has experimented upon children with a solution of equal parts of tincture of iodine and glycerine, rubbed into the skin, and has arrived at the following conclusions. 1. Iodine in tincture, mixed with glycerine and applied to the external integument, is absorbed. 2. This absorbed iodine is invariably found in the secretions and in the urine. (Dr. M. tests for iodine by adding a little starch to the urine in a test-tube and then dropping a few drops of nitroso-nitric acid into it. This gives a blue or violet colour, according to the quantity of starch present). 3. This application may give rise to certain symptoms, usually a variety of mild temporary albuminuria. 4. Dressings containing tincture of iodine may be employed as a means of introducing this medicine into the system when it cannot be taken by the stomach. 5. It must not be forgotten that when this absorption takes place in patients subject to nervoso-vascular erethism, as in certain cases of phthisis, where these dressings are often practised, they may do more harm than good.

On the Pathogenesis of Sudden Death in Typhoid Fever.

M. Huchard has published in *l'Union Médicale*, 1877, an interesting paper on the above subject, in which we find some important therapeutical deductions.

Reviewing the various theories proposed to account for sudden death, M. Huchard does not consider the theory of reflex action as satisfactory, nor is he content with the exclusive theory of cardiac alterations or cerebral anæmia. He believes sudden death in typhoid fever is due to two causes united—encephalic anæmia and degeneration, or simply ischemia, or a paretic state of the cardiac muscles.

He draws the following conclusions from these theories:

1st. To resist the degeneration or weakness of the heart by the administration of digitalis, which is a cardio-vascular tonic, and by the use of coffee, wine, or alcohol.

2nd. To guard against cerebral anæmia and the tendency to bulbary ischemia by opium and injections of morphia.

Extraordinary Cause of Death.

THE strange and remarkable accidents to which disease exposes the human body are well illustrated by a case recorded in *La Presse Médicale*, in which death arose from the rupture of an aneurism of *right gastro-epiploic artery*. It is, indeed, quite unique in medical literature. The patient, who was a very stout woman, complained of a severe and sudden circumscribed pain in the epigastrium, accompanied also with pain in the abdomen. The severe pain was soon followed by collapse, and she died twenty-four hours afterwards.

Medical Reform in America.

A CORRESPONDENT of the *Med. and Surg. Reporter* writes that the Illinois State Board of Health have done a work very satisfactory, not only to the profession, but to the public. The law is not perfect, but will be a stepping-stone to something more. Over 600 strong, non-qualified, have left the State. Every doctor in the State is reading up. Very few students are entering our offices. Western colleges, as a result of the law, have been filled with students. Surrounding States will pass similar laws, in self-defence.

Sarracenia Purpurea in Gout.

ACCORDING to Foucaut (*Arch. der Med. in Ph. Zeit. f. Rüssl.*) the stem and root of sarracenia purpurea is an effective remedy in chronic form of gout. It is employed in form of an infusion, made from one to two spoonfuls of the powder at a time, mornings and evenings, and once during the day one spoonful made into an infusion as a prophylactic. The violence of the attacks becomes greatly diminished, and the alveolar movements more regular.

A New Mydriatic.

M. GALEZOWSKY has experimentalised with an Australian plant possessing a mydriatic action far superior to that of atropine, and which he brought under the notice of of the Biological Society of Paris at its sitting of March 30th.

This substance may be employed on patients in whom there is a difficulty about using belladonna. It appears to have a different action to that of atropine, as it produces stasis of the veins.

Typhus in Roumania.

THE *Revue Médicale de Roumaine*, says that a great number of Russian doctors and sisters of charity have succumbed to the epidemic of typhus now raging in many parts of Roumania. At Fratesti and at Jassy alone—two opposite points—between 40 and 50 medical men, and nearly double that number of sisters of charity have died from it.

The Health of Dublin.

ON a motion by Mr. Meldon, M.P., and in return to an order of the House of Commons, copies were issued last week of the memorial lately presented by the Committee of the Dublin Sanitary Association to his Grace the Lord Lieutenant of Ireland, and any reply given thereto, and of the resolution passed by the Public Health Committee relating to the said memorial. The Public Health Committee, in their resolution on the first report of the Sanitary Committee, state that they think that if a commission of inquiry should be appointed, it should inquire not only into the causes of the high death-rate in Dublin, but also into the best means of abating them.

Dangers from Salicylic Acid.

SEVERAL instances have occurred in which this agent produced disagreeable consequences. Dr. Watelet communicates a paper to a late number of the *Bull. de Therap.* on this subject, entitled "Accidents following the Administration of Salicylic Acid." The details are given of two cases of rheumatism treated by salicylate of soda, one of which was followed by gangrene of the lower extremities, and both by cystitis, obstinate constipation, and coldness of the extremities.

Social Science Congress.

THIS year's annual Congress of the National Association for the Promotion of Social Science is likely to be held at Cheltenham in the autumn, provided there is locally subscribed a sum sufficient to cover the expenses attendant on the proper reception and meetings of the body in the above town. More than a third of the money has already been raised.

Professional Privileges.

THE Medical Societies of Philadelphia are endeavouring to obtain the passage of a law providing that "no person duly authorised to practise physic or surgery shall be allowed or compelled to disclose any information which he may have acquired in attending any patient in his professional character, and which information was necessary to enable him to prescribe for such patient as a physician, or to do any act for him as a surgeon."

THE absence of cold easterly winds last week resulted in a considerable diminution in the high death-rates of the previous fortnight. In the four principal cities the rates of mortality were 23 in Edinburgh, 24 in London, 25 in Glasgow, and 34 in Dublin. The other large towns, having a population of over 100,000, were :—Portsmouth 17, Leicester 18, Nottingham 18, Brighton 20, Newcastle-upon-Tyne 20, Norwich 20, Salford 21, Bristol 21, Hull 22, Sheffield 22, Bradford 23, Leeds 24, Wolverhampton 25, Sunderland 26, Birmingham 26, Manchester 28, Liverpool 29, Oldham 31, and again the highest rate 33 in Plymouth per 1,000 of the population.

DR. GORDON, who for the last thirty-seven years has been associated with Queen's College, Belfast, the latter portion of the time as professor of surgery, has been presented with a life-size portrait of himself, which is to remain in the examination hall, as a lasting testimonial of the esteem in which he is held by his pupils, colleagues, and friends. A half-length copy is also to be painted, and presented to Mrs. Gordon when finished.

A STILL higher death-rate prevailed in St. Petersburgh last week than in any previous week recorded, reaching

the terrible figure of 65 per 1,000 of the population, as against 24 in London. Of the whole deaths nearly one-fourth were from typhus fever. Many other European cities also gave an excessive death-rate, viz., Turin 51, Naples 47, Buda-Pesth 41, Vienna 37, Rome 36 per 1,000.

THE deaths from small-pox in London, which had increased from 48 to 80 in the four previous weeks, declined again to 63 last week; 40 were recorded in the Metropolitan Asylum Hospitals, 3 in the Highgate Small-pox Hospital, one in Westminster Hospital, one in Bethnal Green Workhouse, one in a barge off Millbank, and 17 in private dwelling-houses.

THE Annual Oration at the Medical Society of London was delivered on Monday evening, by Dr. Alfred Carpenter, of Croydon. The Orator chose for his theme, "Alcoholic Drinks as Diet, Medicines, and Poisons." Dr. Carpenter's well known eloquence and the popularity of his subject drew together a large and attentive audience.

HARVARD University has been left a sum of 10,000 dols. on condition that the medical school is thrown open to women. The Faculty of Medicine has accepted the proposal, and it is probable the Supreme Board will do the same.

IT is announced that an examination of candidates for commissions in the Medical Service of the Royal Navy, and for immediate service afloat, will be held at University of London on Monday, 27th May, 1878, and following days.

THE Merchant Taylors Company have made a fourth grant of thirty guineas in aid of the National Hospital for Consumption and Diseases of the Chest, Ventnor.

Correspondence.

A PENNY HOSPITAL FUND.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I trust to your fairness to permit me to state that the suggestion of a "Penny Hospital Fund" to which the MEDICAL PRESS AND CIRCULAR lays claim, is by no means a novelty. One of the plans adopted by the Board of the Hospital Saturday Fund at the commencement of that movement, was the issuing to "trustworthy authorities," in all the large firms, factories, and industrial establishments of the metropolis, of collecting sheets for weekly contributions. This system is still maintained; it is, in fact, the essential feature of the Hospital Saturday scheme, and by a more efficient organisation now introduced will, we believe, be the means of doubling our income during the current year.

Yours, &c.,

J. HUGHES,
Chairman of the Council of the Hospital Saturday Fund.

*** We lay no claim whatever to the suggestion of "A Penny Hospital Fund." From the outset we were against the ostentatious and expensive method of collecting in the streets. It being a working man's fund, we suggested that it would be more in keeping with the object, more agreeable to the hospital authorities and the profession generally, and much less expensive a method, if weekly collections were made all the year round of men in employment by some properly constituted authority in each firm. Each year we have reiterated our views, and we are glad therefore, to hear "that by a more efficient organisation now introduced" this idea will be enlarged and carried out successfully. The next improvement we hope to hear is, that street-touting has been abolished. If the working men have been solicited indoors, they can hardly be expected to give again outside, and the money dropped into the boxes by others can hardly be a sufficient excuse, in the eyes of medical men, for exposing two or three hundred ladies for so many hours to the chances of the weather in the streets of London.—ED. M. P. & C.

"IS OUR PHYSIOLOGY OF THE LARGE INTESTINE CORRECT?"

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In noticing my pamphlet, "Is our Physiology of the Large Intestine Correct?" in your last issue, I observe that you object to the quotation from the *Daily Telegraph*, and I quite admit that at first sight it appears somewhat irrelevant; but hardly so, I think, with regard to the importance of the combination of the *gases*, which, possibly, are at the bottom of the "secret," and account for not only the beautiful natural law there alluded to, but, when this matter is more thought about and impartially investigated by some of the active minds now at work, will further account for many other interesting phenomena, such as the perfume from flowers, &c., &c.

You also rightly *question*, as doubtless that is the only way to arrive at truth, whether the constipation after the operations mentioned is the real cause of the death-rate being lower than formerly? I am glad that you do so, and I will only say that it is at least singular that, whereas the bowels, as a rule, were formerly not allowed to be confined after these operations, and now, as a rule, they are almost invariably *not* interfered with, the inference, at least, was not unnatural, and I venture to think, in the absence of proof, that it is not far from the truth.

Your obedient servant,

11 Kilburn Priory, N.W., C. J. HARRIS.
May 3, 1878.

Literature.

SHORT NOTICES.

(1) "Aids to Forensic Medicine." By William Douglas Hemming, M.R.C.S., &c. London: Baillière, Tindall, and Cox. 1878.

(2) "Fat and Blood, and how to make them." By S. Weir Mitchel, M.D., &c. London: Lippincott and Co. 1878.

(3) "The Whole-Meal Bread Question." By W. Neave Hill. 32mo, 108 pp. 1878.

(1) Medical jurisprudence has been a rather neglected branch of study, its importance being only found out when the student has become qualified, and he is brought face to face with some medico-legal difficulty. There is an awakening interest, we find from the production of such handbooks as the above. The author says: "If this little work tend in any way to induce students to pay more attention to medico-legal science, its object will be amply attained." We think it will do this and more; it will be found a useful aid to memory. In a small compass, many questions, involving civil rights and social duties, are ably condensed, whilst the portion devoted to toxicology, though brief, contains the principal facts, on the nature, detection, and antidotes of poisons.

(2) This is the second edition of an American work by a physician, well and favourably known in the States. We must confess to a certain amount of scepticism on special treatment, which succeeds principally in the hands of the introducer.

The author claims a method of renewing the vitality of feeble people by a continuation of entire rest, excessive feeding, *massage*, and electricity. The term massage is applied to the rubbing or kneading of the body, on a somewhat similar principle to that adopted by the shampooers

in the Turkish bath; it evidently requires a considerable degree of skilful manipulation for its efficient performance. By those who are fond of novelty, the work will repay perusal.

(3) ANY discussion which legitimately bears upon the food question must have an interest to our readers. Unfortunately, perhaps, those who study the subject most closely are those who have a pecuniary interest in promoting a particular theory or preparation. Nor is the bread supply an exception to this rule, as the pamphlet before us testifies. The author, who is a member of the well-known firm of Hill and Sons, bakers to the Queen, has, nevertheless, produced a very readable little book, interlarding his own views with those of most of the leading authorities on the subject. Nor do we consider his opinions less entitled to respect because of a natural bias, inasmuch as they are in accordance with sound physiology and common sense. We have more than once expressed our preference for whole meal to the ordinary white flour, which has necessarily much of its nutritive quality removed in the bran. There are, however, many difficulties to be surmounted before whole-meal bread can come into general use, especially among invalids, and those whose teeth are the reverse of good, the principal one being the extreme hardness of the outer crust, which, even in a new loaf, we have known to turn the edge of the bread knife. Could not this be overcome by the use of hot-water ovens instead of those heated by fire, whereby the glutinous portion of the fibre becomes hardened?

LITERARY NOTES AND GOSSIP.

DR. MCKENDRICK'S "Outlines of Physiology in its Relations to Man" has just appeared as a thick crown 8vo volume of about 750 pages. The illustrations are numerous, and many of them original.

THE last part (X.) of the late Claude Bernard's celebrated work, "A Text-book of Operative Surgery," the translation and editing of which has been undertaken by Mr. Norton, Surgeon to St. Mary's Hospital, is promised in a few days. The work will doubtless achieve as high a reputation in this country as it has on the Continent.

A SECOND edition of Dr. Muter's "Key to Organic Materia Medica" has appeared during the past few days. The work is considerably enlarged, and is altogether a new book.

A NEW and enlarged edition of "Henfrey's Botany," edited by Dr. Maxwell Masters, is expected during the present month. This work is probably the most popular on the subject, especially amongst students at the University of London, where Dr. Masters occupies the Examinership in Botany.

MR. LENNOX BROWNE'S work, "The Throat and its Diseases," of which great expectations have been formed on account of the artistic capabilities of the author, has just been issued; and, upon a casual glance, it certainly does not disappoint us. A novelty has been introduced in the mounting of the coloured plates, which enables the reader to have the illustration side by side with the text at any page, so as to avoid the annoyance of constantly referring to different parts of the book for the study of the plate. The work is certainly the handsomest that has been turned out for some time past.

THE new Quarterly, "Brain," has just appeared, and chaperoned by such names as Crichton Browne, Ferrier, Hughlings-Jackson, and Bucknill, it ought to succeed if there is room for it. But of this we are somewhat dubious, when we consider that there are not 500 members of the profession in the United Kingdom who make cerebral diseases their special study; and that to represent this small section, already two journals—a quarterly and a half-yearly—are in existence, with no great pretensions to a success, notwithstanding that they are both well done, we doubt the chances of the new venture, albeit we should rejoice in its success.

A NEW monthly magazine of "Art" has this month been started by Messrs. Cassell, Petter, and Galpin. The first number is very well done, and from this fact, and the low price at which it is issued, should command success. It will form an interesting and popular journal for the waiting-rooms of medical men.

THE first number of another new quarterly magazine has appeared this month entitled "Burlington House," edited by Mr. Groom Napier, of the Geological Society. It is intended to represent the learned Societies comprising the University of London, the Royal Academy, the Chemical, Geological, and kindred institutions. One of the writers devotes his pen to the laudation of "Pyrethrum Roseum, a Cure for Catarrh," which he describes as the Persian insect powder of the shops. The writer maintains that, although its fine dust on entering the breathing-organs of insects occasions death by asphyxia, in the higher animals and man it acts only as a stimulant of mucous membranes, and is a certain check to colds in the early stage.

"A Manual of Practical Chemistry," by Mr. Muir, Prælector in Chemistry, Caius College, Cambridge, and the second part of Dr. Semple's "Aids to Chemistry" are both announced as in the press. Part I. of this latter work has sold so rapidly that the first edition of a thousand copies has run out in less than twelve months.

WE understand that a testimonial to Mr. George Fleming, the eminent Army Veterinary Surgeon, author of a "Text-book of Veterinary Obstetrics," "Rabies and Hydrophobia," "Animal Plagues," "Veterinary Science and Police," &c., is being raised in recognition of his great literary labours. Sir Frederic Fitzwygram is chairman of the committee, and the idea is a most deservedly popular one, not only in his own branch of the profession, but amongst many members of the medical and other scientific professions where Mr. Fleming's great attainments are known.

Medical News.

Society for Relief of Widows and Orphans of Medical Men.—The annual general meeting of this Society was held on Wednesday, April 24th, at five p.m., by the kind permission of the Royal Medical and Chirurgical Society, in their rooms, 53 Berners Street. The chair was taken by Mr. J. Gregory Forbes, V.P. A letter was read from the President, Sir George Burrows, expressing his regret that absence from town would prevent him presiding at the meeting. From the statement of the affairs of the Society read by the Secretary, it appeared that during 1877 a sum of £2,949 had been voted to the widows and orphans, £63 10s. in excess of the grants of 1876. The expenses of the year were £187 0s. 11d., £27 15s. less than those of the previous year. The receipts, with the exception of legacies and entrance fees, all showed an increase. The interest from funded property had been £2,576 1s. 1d., subscriptions £519 15s., entrance fees 10 guineas, donations £111 4s. Only one legacy had been received during the year—viz., £250 from the executors of James Graham, Esq. The funded property had been increased by the purchase of £593 19s. 10d. Metropoiltan Consolidated Stock. The Society had lost 22 members by death during 1877, and four members had resigned. Among the deaths were mentioned those of Sir Wm. Fergusson, V.P., George Cooper, Esq., V.P., and Dr. Carr, a director. Only nine new members were elected. At the end of the year the Society consisted of 385 members. During the year fresh applications had been received from six widows and two orphans: four widows had died or become ineligible, and three orphans had ceased to receive grants. On December 31st there were 60 widows and 10 orphans receiving assistance from the Society, and four orphans on the Copeland fund. The following gentlemen were elected directors in the place of the six senior who retired by rotation—viz., Dr. Barnes, Dr. Taylor, A. Willett, Esq., G. Easte, Esq., Dr. Andrews, and J. Langton, Esq. A vote of thanks to the editors of the medical journals for their kindness in forwarding in every possible way the objects of the Society was carried unanimously. A vote of thanks to the chairman closed the proceedings.

The German Hospital.—The thirty-third anniversary dinner in connection with the German Hospital at Dalston was held at Willis's Rooms on Thursday evening, Count

Beust, the Austro-Hungarian ambassador, in the chair, the company numbering about 200. In proposing "Prosperity to the German Hospital," the chairman said he would not attempt to make an elequent speech about charity or humanity, lest he should be supposed to speak in diplomatic language, which is generally received with more attention than faith. With regard to the German Hospital, he had always entertained towards it the warmest sympathy, believing it to be a most useful and well-conducted institution, deserving of the warmest support. He had been gratified by a personal visit to it recently, when his good opinion of it was greatly strengthened. Her Majesty the Queen and the Emperor of Austria had each sent a donation of £100. The donations and subscriptions for the evening amounted to £3,700, including an annual subscription of £200 from the Emperor of Germany.

NOTICES TO CORRESPONDENTS.

NOTICE TO SUBSCRIBERS.—Subscribers who have not already paid their subscriptions for last year are reminded that they are now due and should be sent to the publishers, who will be happy to acknowledge their receipt.

DR. PITMAN, Washington, is thanked for his communication and for the information therein contained.

CANDIDATES FOR THE NAVY MEDICAL DEPARTMENT are reminded that the next examination will be held at the University of London on the 27th inst. The necessary forms must be applied for before the 21st to the Director-General of the Department.

A CONGRESS on National Water Supply will be held at the Society of Arts on Tuesday and Wednesday, May 21st and 22nd. The Third Annual Congress on the Health and Sewage of Towns will be held on Wednesday and Thursday, May 22nd and 23rd.

THE Annual *Conversazione* of the Pharmaceutical Society of Great Britain will be held at the South Kensington Museum on Wednesday next, May 15. Cards of admission are obtainable only of the Secretary.

AN EXPERT.—The most common adulterant of sulphate of morphine is sulphate of soda. Apply the usual tests, and you will find that this is so.

A CANDIDATE.—The work has not been translated, but we understand that arrangements are pending for an English edition.

MR. J. B. will find the subject commented upon in our present number. He is thanked for the information.

MR. W. B. PHELAN, Rock Ferry.—There are still vacancies for army surgeons at the Cape. The emoluments offered are: Free passage out and home, with £1 per day, rations, and forage allowance. A twelve months' engagement is guaranteed, or candidates can elect instead to go for the duration of the war, however long or short it may be, and in that case they will receive two months' pay by way of gratuity. Applications must be made in the first instance to Mr. Mackellar, St. Thomas's Hospital, London, S.E.

MR. W. W. and Mr. J. M. are thanked for the information conveyed in their notes. They will observe that it has been utilised in the present number.

THE Dublin Obstetrical Society will meet on Saturday next at eight o'clock at the College of Physicians, when the following communications are set down for reading:—Dr. Kidd, "On Diagnosis of Dropsy of the Amnion;" Dr. Atthill, "On the Clinical Report of the Rotunda Hospital for 1877;" Dr. More Madden, "On some Diseases of the Placenta;" Dr. Martin, "On Super-fœtation."

MR. B. S.—Communication received on Tuesday morning as we were going to press. Will appear in our next.

DR. DOBELL will please receive our best thanks.

AN URGENT CASE.

Drive, drive, drive,
Or else you will surely be late;
Drive, drive, drive,
Drive at your fastest rate.
Thus said a messenger beery,
To a doctor tired and weary;
Drive, or you will surely be late.

Drive, drive, drive,
Your horse aged and worn;
Drive, drive, drive,
Your old chain broken and torn.
Thus said the messenger beery,
To the doctor true still cheery;
But he found he was'nt too late.

Drive, drive, drive,
Don't wait for your horse to be fed;
Drive, drive, drive,
Or you will find the old woman dead.
But the old woman had got the toothache,
And deuce a medicine she'd take.

Drive, drive, drive
Homeward, tired and weary,
Drive, drive, drive.
If I had that messenger beery,
How I'd like to pull out his teeth.

J. W. M.

VACANCIES.

Bethlem Royal Lunatic Asylum.—Resident Medical Superintendent. Salary, £700, exclusive of pupils' fees, &c. Printed forms to be obtained of Mr. Jeaffreson, Bridewell Hospital, London, S.E. Election, 16th inst. (See Advt.)

Birmingham.—Medical Officer for No. 3 District of the Parish. Salary, £175, with fees extra. Endorsed applications to be sent to the Clerk to the Guardians before the 14th inst.

Bristol Royal Infirmary.—House Surgeon. Salary, £100, with board, lodging, &c. Applications, with testimonials, to the Secretary before the 11th inst.

Gloucester General Infirmary.—Surgeon and Assistant Surgeon on the Staff. Honorary. Testimonials to the Secretary before the 30th inst.

Hants County Hospital, Southampton.—House Surgeon and Secretary. Salary, £100, with board. Applications, under cover, to the Secretary before the 27th inst.

Manchester Royal Infirmary.—General Superintendent and Secretary. Salary, £350, with board and residence. Applications, with testimonials, to the Secretary before the 18th inst.

Manchester, St. Mary's Hospital and the Manchester Lying-in Hospital.—Medical Officer to visit patients at their homes. Salary, £80, with board and residence. Apply to the Secretary before the 17th inst.

Roscommon County Infirmary.—Apothecary and Registrar. Salary, £60, with apartments and allowances. Election, 17th inst.

St. Pancras, Middlesex.—Medical Officer of Health and Examiner of Gas. Salary, £300. Gentlemen appointed must reside within the parish. Application forms to be had from the Clerk, Vestry Office, Pancras Road, N. Election, 15th inst. (See Advt.)

Wilts County Lunatic Asylum.—Assistant Medical Officer. Salary commencing at £110, with board, &c. Endorsed applications before the 15th inst to the Clerk to the Visitors, the Asylum, Devizes.

APPOINTMENTS.

ATKINSON, R., M.R.C.S, Senior House Surgeon to the Royal Free Hospital.

BROCK, A. C., L.R.C.P.L., M.R.C.S.E., Assistant House Surgeon to the General Hospital, Bristol.

BULLOCK, J. E., M.R.C.S., House Surgeon to St. Peter's Hospital, London, W.

COOMBS, S. W., L.R.C.S, L.R.C.P.Ed, Resident Surgical Assistant to the Glasgow Royal Infirmary.

DAVIES, Mr. E., Resident Medical Assistant to the Glasgow Royal Infirmary.

FERGUSSON, R. A., L.R.C.S., L.R.C.P.Ed., Resident Surgical Assistant to the Glasgow Royal Infirmary.

HAY, H., M.B., C.M., Assistant to the Extra Physicians of the Royal Hospital for Sick Children, Edinburgh.

HAYWARD, T. E., M.R.C.S.Eng. & L.S.A.Lond., Resident Medical Officer to the East London Hospital for Children.

HERBERT, Mr. J., Resident Surgical Assistant to the Glasgow Royal Infirmary.

IRWIN, J. A., M.D., M.R.C.S.E., a Medical Officer to the Southern Hospital, Manchester.

Births.

CARMICHAEL.—April 30, at Wyrley Grove, Staffordshire, the wife of William Carmichael, M.D., of a son.

FLETCHER.—May 1, at Ballinasloe, co. Galway, the wife of R.V. Fletcher, M.D., of a son, stillborn.

HARVEY.—April 28, at Queenstown, co. Cork, the wife of Surgeon C. A. Harvey, Her Majesty's Indian Medical Service, of a son.

M'CLOSKEY.—April 29, at Derry, the wife of Joseph R. M'Closkey, M.D., of a son.

NICHOLSON.—April 30, at Hanover, the wife of Gilbert de P. Nicholson, M.D., of a son.

Marriages.

BRAYN—NEGUS.—May 2, at St. Mary's, Kingston, Portsmouth, Richard Brayn, L.R.C.P., M.R.C.S., to Laura Jane, daughter of Fisher Negus, Fleet Surgeon, R.N.

POWER—COOKE.—April 30, at Ahada, co. Cork, Joseph Power, M.D., Borrisoleigh, co. Tipperary, to Frances Josephine, eldest daughter of the late Peter J. Cooke, Ahada, co. Cork.

Deaths.

CLARKE.—On April 20, at Upperlands, Maghera, Jackson N. Clarke, M.D., aged 63.

COLLINGWOOD.—On April 20, at Ganden Road, Clapham, William Percy Collingwood, M.R.C.S.E., aged 57.

CUNNINGHAM.—On April 24, at Hailsham, Sussex, James Mackay Cunningham, M.D., aged 75.

CROFT.—On April 30, at Old Charlton, Kent, Catherine Mary, widow of Charles I. Croft, F.R.C.S., aged 59.

FURNIVALL.—On April 29, at Boulogne-sur-Mer, John James Furnivall, M.D., M.R.C.P., aged 85.

MACPHERSON.—On April 7, at Moor Street, Birmingham, Robert Samuel Macpherson, L.K.Q.C.P.I., aged 39.

NICHOLSON.—On April 25, at Ryder Street, St. James's, London, Robert Nicholson, M.D., Surgeon Major Bombay Army, formerly of Banford, co. Down.

PRETTY.—On April 23, at Quebec Lodge, Lower Norwood, Wm. Pretty, M.R.C.S.E., aged 86.

ROBSON.—On April 17, at Lonsdale Terrace, Edinburgh, Wm. Robson, M.D., aged 43.

WILMOT.—On April 30, at Tunbridge, John Branston Wilmot, M.D., F.R.C.P., aged 72.

ALCOHOLIC DRINKS: AS MEDICINES, AND AS POISONS. (a)

By ALFRED CARPENTER, M.D. Lond., M.B., J.P.,

President of the Croydon Microscopical Society, Lecturer on State Medicine, St. Thomas's Hospital, &c.

The first question which we have to solve is, whether any force can be produced out of alcohol *qua* alcohol, either as animal heat, muscular power, or nervous energy. Is it capable of being at all utilised in the animal economy? Dr. Henry Bennett says ("Nutrition in Health and Disease," p. 64) that alcohol feeds organic combustion, and creates heat, and even Dr. Richardson ("Temperance Lesson Book," p. 182) says that "in its first action it causes the warmth of the body to rise." But there is then a divergence of opinion: on the one hand, eminent men agree with Dr. Bennett, and assert that alcohol is rapidly decomposed, and heat disengaged. Dr. Parkes, from his practical observations, was satisfied that it did evolve heat, though it lowered the temperature for a short time after being taken; whilst others, equally eminent, affirm that there is no utilisation in the ordinary sense, and some say that the whole of the alcohol is passed through the body and is expelled without any of it being changed into force-producing matter. I cannot endorse this opinion, because it is contrary to almost universal therapeutical experience. Every medical man in extensive practice must have seen cases which, now and then, have fallen to my lot to witness, in which life has been prolonged for many months without any other nourishment than that which was contained in the spirituous liquors or wines which the patient would alone consume; cases in which it was impossible for life to have been sustained upon the few grains of organic substances which were contained in the colouring matter or extractive of the liquor, or in the sugar which is sometimes given with the stimulant. It has been shown that dilute solutions containing alcohol of about the strength in which it is likely to be found in the body, viz., 1 in 1,000, if passed several times through six inches of a silicated carbon filter, metamorphosed the alcohol into complex products non-volatile at the boiling point of water; the alcohol being changed by this plan of proceeding into glycol, which is considered one of the saccharine group. If this be a possible contingency, it may be transformed into force in the human economy under certain unknown circumstances, and as such it may be useful without danger as a luxury. It may be argued by the austere ascetic that all luxuries are evil, and that they should not be used at all. I need not stay to consider this line of argument. To abolish all luxuries would be to bring enormous misfortunes upon the whole race of mankind for which there could be no excuse; and I must assume that a luxury which is not immediately injurious may be fairly used by all who can afford it.

It is forcibly argued by some whose opinion is worthy of deep attention, that alcohol is hurtful under all circumstances. They state that it is immediately injurious to those in health, and that there are other stimulants equally, if not more, useful which could be employed in disease. They contend that its ordinary sale should be prohibited on that account, in the same way that arsenic or strychnine is prevented from being a common article of merchandise. Let us now look into this view of the question, premising again that the individual experiences of those who have been accustomed to the use of stimulants are not in any way to be depended upon for an accurate estimate of their effects, and that their evidence is worthless for scientific purposes.

If alcohol is exhibited in potent doses to one unaccustomed to its use, there is no doubt of its injurious and even fatal results; but such would also be the effect of the exhibition of phosphorus, sodium, or potassium, and yet they exist as necessary elements in many foods, and are absolutely required to enable the body to be built up properly. Because, therefore, a large dose of alcohol, phosphorus, or calcium is injurious, it does not follow necessarily that a small one is mischievous likewise. Indeed, if lime and common salt are withheld the constitu-

(a) Abstract of the Annual Oration delivered before the Medical Society of London, May 6th, 1878.

tion is sure to suffer ; we have rickets established in the one case, and in the other the body is tormented by parasitic life. We must not assume that because a large dose is injurious a small one is so also. Lime and salt are necessaries of life, and yet they are injurious in large doses, and it is not an argument against their use in small ones. Alcohol, like lime and salt, may be beneficial if used at the proper time, and it ought not, therefore, to be absolutely prohibited as a common article of commerce unless it can be shown that some injurious sequence is sure to follow sooner or later upon its use in small doses.

We must look a little closer into its action upon animal life before we can solve this point. The first deduction to be made from its continued use is, that the body after a short interval becomes very tolerant of its effects, and apparently, the more, in moderation, a man takes into his system, the more he can carry without apparent injury. Those accustomed to the daily use of alcohol can take a much larger quantity with impunity than the teetotaller can do. One man may take a bottle of wine and half a pint of brandy every day of his life, making 365 bottles of wine and nearly 100 bottles of brandy every year, whilst another man only takes a bottle on a given day once a week, or three or four glasses of brandy and water on Saturday night. The one may be of the race of "fine old English gentleman," who never transgresses the rules of propriety, and goes honoured sooner or later, generally sooner, to his grave with blessings on his head, whilst the other becomes an habitual drunkard, a transgressor of the law, and an outcast of society, although he does not consume one-sixth part of the liquor which is taken apparently with impunity by the other. This result shows that conditions vary very much in different constitutions, according to the regularity with which the dose is taken, and alcohol, or some of its constituent elements, collects much more rapidly in some habits of body than in others. It differs, within certain limits, from most re-agents, and helps to protect those using it regularly from its own evil effects. In this it appears to be allied with tobacco, and also with certain miasmatic influences which require some constitutions to be acclimatised before they can bear that which is manifestly injurious in its first effect, however they may be able to stand against its bad influence after a time.

It is stated by microscopical observers that alcohol acts immediately upon the blood-corpuscles as well as on the fibrine which is contained in the liquor sanguinis. It is said that one part of alcohol mixed with 500 of blood interferes with the power of the corpuscle to absorb oxygen ; it abstracts water from the blood-discs and makes them adhere together in masses in the blood-vessels ; it also causes the plastic or fibrinous part of the blood to coagulate, which then collects in the capillaries, and the current may be thereby stopped.

From frequent observations I incline to believe that this is true, and that this result explains some of those unfortunate cases which now and then occur to the obstetric practitioner. The free exhibition of alcoholic stimulants to the weak and debilitated, especially when there has been hæmorrhage or long-continued suffering, and perhaps too great dependence on stimulants, has led to the sudden development of embolism. A clot of fibrine has been deposited rapidly in the heart or large blood-vessels, and the patient is dead in a very short time. I have also seen many cases of paralysis and epileptiform convulsion which had been caused by embolism, and which, in my opinion, had been promoted by alcoholic saturation. Such cases have done well, and have ultimately recovered, if alcohol has been superseded ; but if it has been persevered in, in most instances which I recollect there was a continuation of the disease. An excessive quantity of alcohol does impede the purification of the blood, and the elimination of carbonic acid by obstructing endosmose and exosmose in the lung capillaries ; the purple tint which pervades the skin of the regular toper is sufficient proof that this is true. Observation shows that the exhalation of carbonic acid is decreased in quantity after the imbibition of alcohol.

Whilst these are undisputed facts as regards large doses of alcohol, it has not been shown that a similar result follows from the smaller quantities which are found in the weaker drinks, such as natural wines and weak beers.

Alcohol is not cumulative under ordinary circumstances, or the man who takes his bottle of wine daily would suffer more and sooner than he who only takes a bottle one day in the week ; but it is cumulative under some conditions, at present unknown, and in which it is probable that the ordinary elimination or oxidation is interfered with, so that the toper, who could formerly take his bottle with ease, gets quite drunk by taking three glasses of his favourite liquor. One very eloquent writer and former orator to this Society says, that "we may trust a great deal to instinct, and that tastes are, generally speaking, expressions of the wants of the system." I consider this a most dangerous argument to use, for no man, taking stimulants, can be himself aware of all the harm that they may be doing to his constitution, or know the time when they may become cumulative. All those who indulge in any kind of vicious practises would be glad to be able to rest upon such a dictum, and to affirm and excuse themselves by affirming that their vicious tastes "were but the expression of the wants of the system."

It appears to be supported by a sufficient weight of evidence that, when once the system has been exposed to the full influence of alcohol in such a way that a portion of the blood has been so acted upon that its discs have become corrugated and some of the fibrine coagulated by its action, a cumulative effect may begin, and, with that cumulative effect, there will be developed a taste for more which prevents the instinctive desires of the individual being any guide as to the real wants of the system so long as any altered material exists in the blood ; the lightest kind of wines generally contain 10 per cent. of alcohol, so that they must be diluted with five times their amount of water to reduce them to a harmless condition. The reduction is seldom effected in this country, although the general consumption at the dinner-table, of saline waters which has lately come into fashion, is tending greatly in the direction indicated. Porter, stouts, and ales, all contain at least double the amount of alcohol beyond that which would make them safe for absorption at all times, unless freely mixed with other things. To take them, therefore, on an empty stomach tends more rapidly to bring about the point of saturation than when food is taken with the drink.

Alcohol transudes most rapidly through membrane, the rapidity of transudation varying very much according to the stage of dilution, and in its transudation it acts upon the membrane, or is itself acted upon. It is quickly conveyed to all parts of the body, and we have no means of judging where it is likely to manifest its first effects, neither have we any means of knowing when the limit is reached beyond which it will not be safe to allow blood disturbance to proceed. The alteration in the shape of a few blood corpuscles, the interference with their diffusive power, the interference with the transudation power of membrane, or the coagulation of a few grains of fibrine, are of comparatively little consequence, especially if the place is one of secondary importance; but when the number of altered corpuscles passes beyond a certain percentage of the whole volume of blood, evil must result. This percentage is much more rapidly reached in some habits of body than in others ; it will depend very much upon the power of those organs to do their duty, whose function it is to remove the altered fibrine and imperfect oxygen carriers from the circuit. If they are defective deterioration will be much more rapid. Thus, of two men, each taking the same quantity of liquor in the course of a month, one taking it only with food and the other on an empty stomach, the latter becomes rapidly saturated, the former escapes without serious damage.

If coagulated fibrine is not removed as soon as coagulation takes place, if it gravitates to some one organ and impedes circulation there, we have the commencement of those organic changes which are constantly found in the bodies of the intemperate classes, by means of which their habits are unerringly revealed to the pathologist. The fibrine may be removed at first without setting up mischief, but the altered blood corpuscles and interference with physical power of membrane increases the evils which arise from want of oxidising power, and fatty degeneration sooner or later follows.

Here is the great difficulty which meets the view of all those who have considered the action of alcohol in an unbiassed manner, and which has led so many among us to become total abstainers. They refuse to take alcohol as a luxury, and they determine that they will not in any way encourage its habitual use among the people. The evil is so great and the resulting good so small, that they prefer to do without the good and so avoid the evil; and as society is at present constituted they are probably right. Still, the lighter wines, if entirely unfortified, and the weaker beers may be taken with impunity; they may even assist digestion and be of advantage with, or immediately after, food. If taken with other food, when great exertions are being made, and when there is a call upon the stomach for fuel to supply waste of tissues, there is sufficient evidence to show that they enable the machine to obey that call with better effect than would be the case if stimulants were altogether withheld; but if the effort is continued from day to day, beyond the ordinary capacity of the machine, and that effort it sustained by more fuel in the shape of stimulant, the human machine, like all others, must wear out sooner than it would otherwise do.

It follows, therefore, that the habitual use of strong drink even in a diluted form, for the purpose of enabling the receiver to do more work, is necessarily hurtful, unless that dilution is much less than it usually is; whilst, if the exertion is not called for, the effect must still be hurtful by setting up organic changes in the tissues of the body itself, and laying the first foundations of disease.

Whenever, therefore, the consumption of alcoholic drinks exceeds the quantity which gives rise to the probability that more than one part of alcohol to 500 of water may exist in any part of the circulation, harm, in some form or other, must result. That harm need not necessarily be permanent, and its cause may be removed altogether from the system, or it may be partially removed, a particle of matter being left *in situ*, which will act as a foreign body when alcohol is again taken, aggregating to itself fresh coagulated matter or freshly agglutinated corpuscles, by which the symptoms of alcoholic excess are rapidly induced, when those particles are situated in any of the primary nerve centres.

We may fairly assume that there are occasions in which stimulants may be useful, and even necessary; but as habitual drinks they must be hurtful unless more diluted than we are accustomed to take them, and it appears to be our duty as physicians to forcibly state this fact to those consulting us, and to advise their non-use in daily life.

Having come to this conclusion as regards their use as common articles of food, we may now inquire when they are likely to be beneficial as medicines. To enable us to answer this question satisfactorily, we must study their effects a little more closely than we have yet done.

(To be continued.)

A SHOCKING case of inhumanity occurred in Sheffield last Friday. Eliza Smith, wife of Thomas Smith, militiaman, called up for service, was obliged to leave her lodgings through destitution. When in London Road she was suddenly seized with labour pains, and pleaded to be allowed to enter people's passages. They all refused, and several barred their doors against her; and a crowd collected and witnessed her give birth in the street to a still-born child. The woman was afterwards attended by a midwife who was passing.

ON ASTHMA.

By J. B. BERKART, M.D.,
Assistant Physician to the City of London Hospital for Diseases of the Chest.

(*Continued from page* 383.)

DEFINITION, PATHOGENY, AND ETIOLOGY.

B. *Etiology.*

I.—PREDISPOSING CAUSES.

LIKE most other morbid phenomena, asthma also depends upon the concurrence of predisposing and exciting causes. Of these etiological elements, the former are decidedly the more important. They alone are capable of explaining why, of two individuals who exposed themselves to the same injurious influence, the one escapes unhurt, whereas the other is seized with dyspnœa. The present inquiry has shown that the tendency to asthma is produced by definite organic lesions of the respiratory organs. Only the imperfect means of diagnosis and the rarely fatal issue of the disease, at the time when its clinical features are most characteristic, are the cause that the existence of those lesions has been so constantly overlooked. Still, the known pathology of the antecedents and sequelæ permit the safe inference that the stage intermediate between them also corresponds to certain textural changes.

1. *Anatomical Lesions.*—The anatomical details vary in extent and intensity. A copious exudation of serum and white blood-corpuscles is already stated to be the starting-point of the affection. Constitutional and local causes determine the subsequent fate of that exudation. Of the former, little is definitely known; only this much may be supposed, that the blood must be deprived of some of its essential properties on account of the great loss of its constituents, which, after their complete development, are destined to perform the most important functions, but whose regeneration is retarded owing to the existing febrile process. As regards the local causes, there is reason to believe that the crowding of the leucocytes in the bronchial and interstitial tissue not only impedes their development, but leads to compression and obliteration of the adjoining capillaries. An extensive thrombosis of the capillaries, (*a*) whether from stasis, compression, (*b*) or endarteritis, (*c*) thus diminishes the supply of arterial blood to the affected parts. The white blood corpucles are softened and reabsorbed. This process of liquefaction implicates, at the same time, the tissues in which it takes places. The bronchial muscles, paralysed by the preceding inflammation, now undergo fatty degeneration; (*d*) while the elastic fibres become hyaline and brittle, each fragment being composed of round or oval granules. (*e*) Atrophy of the contractile and elastic elements of the lung is, then, the result of those degenerative changes. As the pleural tension, however, remains the same, while the resistance of the atrophic lungs to the excentric traction is diminished, the bronchioles and alveoli are consequently dilated. This atrophous dilatation (*f*) is either cylindrical or saccular, and is most marked in the bronchioles of the fourth subdivision, extending hence to the alveoli, so that the dilatation of the one occasionally preponderates over the other. Such lungs, inflated and dried, present the aspect of a large-holed sponge, the cavities varying in size from that of a hemp-seed to that of a pullet's egg.

Not unfrequently the white blood corpuscles are, for

(*f*) Buhl, op. cit., p. 21.

various reasons, endowed with sufficient vitality, so as to develop themselves into permanent tissue. An active hyperplasia and hypertrophy are then observable in the parenchymatous stroma of the lungs. This genuine peribronchitis and interstitial pneumonia also lead to obliteration of capillaries and air-vesicles by the firm connective tissue, the fibres of which radiate in all directions; while the contractile and secreting structures of the bronchi are either destroyed (*a*) or greatly impaired in their functions and nutrition. Here, again, the tonus and elasticity of the lungs are so greatly diminished, that the pleural tension readily effects the "hypertrophous bronchiectasis" (*b*) and the vicarious emphysema.

Unless the volume of the blood decreases in proportion to the reduction of the respiratory surface, it is evident that the pervious vessels of the lungs must be in a state of vicarious distension. But the destruction of the pulmonary capillaries generally takes place at the time when development is most active, and when, with the growth of the osseous system more particularly, the volume of the blood also increases. Hence, the greater amount of work which the right side of the heart is now called upon to perform, in order to force a relatively larger quantity of blood through the contracted lungs, produces hypertrophy of the organ,—a consequence to which Dr. Peacock (*c*) was the first to call attention. Under the influence of this increased pressure, the pulmonary vessels, unprovided as they are with a vascular tonus, (*d*) readily dilate; and, in order to compensate for the loss of the capillaries, extensive anastomoses form between the pulmonary artery, on the one hand, and the bronchial and pulmonary veins on the other, by means of vascular arches, remarkable on account of their great length, their equable diameter, and their want of branches. (*e*) The surface of the bronchial mucous membrane then appears studded with granular or villous elevations; on microscopic examination, these are found to be vascular papillæ, pyramidal or club-shaped, consisting of a tortuous vessel, elevated over the surface and surrounded with connective tissue. (*f*)

The inundation of the pulmonary parenchyma with nutritive fluid causes enlargement of the bronchial glands, which, as a rule, participate in all affections of either the surface or substance of the lungs. In many instances, that enlargement dates from the whooping-cough and measles, and diminishes or increases with the diminution or increase of the quantity of, as well as the obstacles to, the lymphatic current. Other changes in the bronchial glands, beyond the mere hypertrophy, are mainly determined by the constitutional proclivities of the patients.

So long as the energy of the heart remains unimpaired, the organism is in no perceptible manner affected by the reduction of the respiratory surface, but when the cardiac muscle degenerates, as it necessarily does, in consequence of the overstrain, a general dilatation of the venous system manifests itself. Varicose veins of the lower extremities, hæmorrhoids, varicocele, and dilatation of the ovarian and uterine plexus, (*g*) are almost constant occurrences in asthma. Less frequent, but by no means rare, is the enlargement of the thyroid gland, (*h*) which apparently comports itself towards the lungs as the spleen does towards the liver in cases of hepatic cirrhosis. Occasionally, under the influence of the increased venous pressure, (*a*) a kind of erectile tissue forms upon the turbinated bones, (*b*) and naso-pharyngeal polypi develope themselves, which Voltolini (*c*) erroneously regards as causes of asthma.

According to the observations of Verneuil (*d*) and the experiments of Ranvier, (*e*) the varicose dilatation of a vein always commences at its radicles. As the healthy nutrition and function of an organ depend, to a great extent, upon the integrity of its capillaries, it is readily conceivable that profound changes of the surrounding tissues are liable to occur and actually take place in consequence of that dilatation; for the increased pressure in, and the thinning of, the venous radicles, favour the escape of serum and white blood-corpuscles. (*f*) The various "catarrhal" affections of the external and internal linings of the body,—the skin and mucous membranes,—are thus the consequence of, and in their turn increase the tendency to, asthma.

2. *Diathetic Disorders.*—The connection between skin-diseases and gout on the one hand, and asthma on the other, has been somewhat exaggerated and also perverted. The theory of Duclos and Trousseau, according to which a "herpetic principle" in the blood attacks in a fitful manner, at one time the skin, at another the bronchial mucous membrane, is devoid of all positive proof. All the reported cases, upon which that theory relies, are certainly not conclusive in its favour. A house-painter suffers in 1859 from eczema, which completely subsides; but in 1861 he has a dyspnœal seizure. Moutard Martin observed a case in which an eczematous eruption was followed, at an interval of *six years*, by "asthma." (*g*) What influence the cutaneous affection could have had in these cases upon the appearance of the dyspnœal seizures, is beyond comprehension. If, nevertheless, skin-diseases and asthma are frequently associated, the reason of that occurrence must be sought in the nutritive changes, which, by the dilated venous radicles are produced in the external integument. "Eczema" of the lower extremities generally accompanies the varicose dilatation of their veins; (*h*) but this vesicular eruption is only an indication of the facility with which serum and white blood-corpuscles escape through the altered vascular walls. Under these circumstances, the causes productive of cutaneous affections find a very favourable soil for the display of their effect in the asthmatic. And, as extensive congestion of the skin would necessarily produce a collateral anæmia of the lungs, in the same manner as, but much more effectually than, a sinapism,—judging from the extent of the surface implicated,—the alternation between asthma and a dermatosis can be readily accounted for.

A similar interpretation may, perhaps, be placed upon the association of gout and asthma. Both seem to be the co-ordinate results of the same constitutional cause; for an absolute or relative plethora, such as it undoubtedly exists in both diseases, is sufficient to explain the origin of the organic lesions of the lungs, as well as that of the articular affections. As regards the supposed retrocession of gout to the lungs, there is, as yet, no fully ascertained case in which its characteristic deposit has been found in that organ. But if lithic acid were to accumulate in the lungs, there is little doubt that it would here produce the same effect as it does in the joints.

3. *Inheritance.*—A hereditary element seems to be influential in the production of the asthmatic tendency.

About forty per cent. of the patients state that some members of their families had been subject to the disease. Yet, in eleven out of seventeen cases, that hereditary predisposition is traceable to grandfathers and grandmothers. (*a*) Considering, however, the vague application of the term asthma, and the fact that atrophic emphysema, with its intermittent dyspnœa, is almost a physiological attribute of old age, no great reliance can be placed upon those statements. This much, however, is certain, that feeble parents produce a feeble offspring, and that just as physiognomy and mental disposition are transmitted, so a peculiar weakness of texture and a deficient power of resistance to, and of repair after, injury, may be communicated from one to another generation. Where the paroxysms appear soon after birth, it does not follow that, as Hyde Salter suggests, (*b*) the disease is congenital. A premature respiration of the fœtus on its passage through the maternal canal may, by the aspiration of fluid, lead to atelectasis or bronchitis.

4. *Age.*—The first ten years of life are most obnoxious to asthma, and the reason is, that infantile bronchitis and catarrhal pneumonia, complicating measles and whooping-cough, are most frequent at that time. But, though the foundation of the disease may be laid at so early a period, its manifestation depends upon the extent and intensity of the primary affection. In comparatively rare instances, the predisposition slowly develops, and declares itself only in youth and early manhood. At a more advanced period of life, the involution of the lungs, premature or in connection with that of the body in general, constitutes a very marked liability to the dyspnœal paroxysms. In old age, however, asthma soon loses its peculiar characteristics, inasmuch as the intermittent is converted into a permanent dyspnœa, while the anatomical lesions, upon which this depends, are readily discernible.

5. *Sex.*—Asthma is decidedly more prevalent among men than women. How far the wear and tear of the body, proceeding from habits and occupation, are accountable for its greater prevalence in the male sex, is not quite known. The supposition that those suffer most who most expose themselves to the inclemencies of the weather, as, for instance, "costermongers, cabmen, and Covent Garden porters," (*c*) is not borne out by facts. On the contrary, those who lead a sedentary and indoor life supply the greatest contingent of asthmatics. The occupation, however, can have no bearing upon the question in the first ten years of life, where that preponderance of the male sex is already noticeable. It appears that the greater frequency of asthma in the latter is mainly due to the greater mortality of the female from whooping-cough. (*d*)

6. *Occupation.*—According to Hyde Salter's statistics, (*e*) about seven-ninths of the male asthmatics are gentlemen, and more than three-fourths of the female asthmatics are ladies. Thus the upper-middle and upper classes would seem to contribute more than three times as many cases of asthma as the lower. Salter suggests that the greater frequency of the disease among the better classes may be attributable to the promptitude with which they bring their suffering under medical cognisance. Much, however, is due to the medical and sanitary advantages which the children of the rich possess. They are thus enabled to pull through the catarrhal pneumonia that lays the foundation of their disease, and to survive as asthmatics; whereas the children of the poor, when suffering from that affection, are cut off at once. (*e*) Statistics of those who seek advice at hospitals are not at hand. This much, however, is certain, that chronic bronchitis, with dyspnœal paroxysms, which among the well-to-do is generally called spasmodic asthma, is by no means of rare occurrence among the poor. Still, it appears as if the children of the rich were more liable to catarrhal pneumonia than those of the poor; for, while the latter pass, ill-clad and exposed to the inclemencies of the weather, through their whooping-cough, in the streets, with no other inconvenience than the temporary interruption of their play by a fit of coughing, the former are confined to rooms, and are anxiously guarded against the access of air—the much-dreaded draught. The observations of Bartels (*a*) tend to show that in badly ventilated rooms inflammation of the bronchi rapidly spreads to the pulmonary tissue. And Geigel (*b*) also states that, while the most neglected children suffer mainly from derangement of digestion, those better cared for are chiefly subject to pulmonary affections.

SOME REMARKS ON THE PREVALENCE OF SMALL-POX IN DUBLIN. (*c*)

By THOMAS WRIGLEY GRIMSHAW, M.A., M.D.,
Fellow and Censor of the King and Queen's College of Physicians, Physician to and Lecturer on Medicine in Steevens' Hospital, Consulting Physician to Cork Street Fever Hospital.

PREVIOUS to the autumn of 1876, Dublin was almost free from small-pox, since the close of the epidemic of 1871-73. In 1876 the disease made its appearance in the towns of the north of England which are in daily communication with Dublin, and thence, as I shall show presently, it was introduced into Dublin, where it found a ready soil for its propagation in consequence of the unsatisfactory state of vaccination.

Before I proceed further, I wish to refer to the relations between the prevalence of small-pox and the progress of the practice of vaccination in Ireland and in Dublin. Statistics compiled from the reports of the Census Commissioners show in a most conclusive manner the great benefits which vaccination has conferred on the community.

During the decade 1831-41 there was not any public provision for vaccination in Ireland, and, accordingly, small-pox had its full sway, as even those who desired to be vaccinated found it difficult to be so, unless they belonged to the wealthier classes of society. During this decade *one-twentieth* of all the deaths in Ireland reported to the Census Commissioners were caused by small-pox, and the average rate of mortality from small-pox was 7·095 in every 10,000 living. During the decade 1841-51 the first Vaccination Act—namely, the 3rd and 4th Vic., cap. 29—came into force in Ireland, and public vaccinators were provided by the Poor-law Guardians; and thus vaccination was *offered*, but not made compulsory on the people. The result of affording these facilities was, that vaccination became more general and the average death-rate from small-pox fell from 7·095 to 5·842 per 10,000 living.

During the decade 1851-61 further facilities for vaccination were afforded by the passing of the Medical Charities Act, 14 and 15 Vic., cap. 68, by clause 19 of which every dispensary medical officer was "required to vaccinate all persons who came to him for that purpose." Thus all excuse for neglect of vaccination was removed by the State—the result being that this provision was largely availed of, and the average death-rate from small-pox fell from a ratio of 5·842 to 2·195 per 10,000 living.

During the last decade, 1861-71, for which we have records, a most important change took place in the vaccination laws. On January 1st, 1864, during the prevalence of small-pox, the Compulsory Vaccination Act, 26 and 27 Vic. cap. 52, came into force, so that during seven years of this decade all persons born were bound to be

(*c*) Being an abstract of a paper read at a meeting of the Medical Society of the King and Queen's College of Physicians.

vaccinated. The result of the enforcement of this Act is remarkable; for, during the decade, the mortality from small-pox fell to an average of 0·759 per 10,000 living—the total number of deaths returned to the Census Commissioners being but 4,113, of which 1,274 occurred before the Act came into force.

From the year 1864 we have more accurate means for judging of the relations between small-pox and vaccination. In that year the Act for the Registration of Births and Deaths in Ireland, 26 Vic., cap. 11, and the Compulsory Vaccination Act, 26 and 27 Vic., cap. 52, both came into force on the 1st of January.

The vaccination returns of the Irish Local Government Board, although not complete, are accurate, and include a very large proportion of the cases of vaccination in Ireland—namely, all those performed by the dispensary medical officers; those performed by private practitioners, or by the old Cow-pock Institution in Dublin, are not included.

An examination of these returns gives the following results :—

In 1864 a serious epidemic of small-pox (causing 854 deaths) prevailed, which had commenced in the previous year. The enforcement of the new Act, the panic caused by the epidemic, and the circular of the Poor-law (now Local Government) Board had stimulated vaccination to such an extent that 191,810 persons were vaccinated by the dispensary medical officers during the year ending September, 1864, the number of vaccinations exceeding considerably the number of births registered, showing that a considerabie number of persons had been either re-vaccinated or had postponed their vaccination until forced to it by the dread of small-pox. The result of this activity in vaccination was a diminished prevalence of small-pox, the deaths from this disease falling to 461 in 1865, and further falling the next year, when the epidemic ceased. The panic having now subsided, and the primary effect of the enforcement of the new Act having passed, vaccination became neglected, and steadily fell to 125,672 in 1869, and but few persons who had been neglected or ignored vaccination submitted to the operation, only 7,760 being recorded, against 71,982 in 1864-65.

On March 7, 1865, the Poor-law Commissioners issued a circular to all boards of guardians calling attention to the fact that many persons did not comply with the Compulsory Vaccinationn Act of the previous year, and impressing upon the guardians the necessity of stoutly enforcing the provisions of the Act. This seems to have the desired effect, for the number of infantile vaccinations increased considerably, and continued to increase during the three following years. During this period, as might have been expected, the number of vaccinations of persons not within the operation of the Act declined to a marked extent, so that the total number of vaccinations fell considerably.

In 1866 the Poor-law Board did not consider it necessary to issue any circular about vaccination, rightly believing that their previous circulars were producing the desired effect.

On February 6th, 1868, the Poor-law Board issued another circular calling the attention of boards of guardians to the diminution of small-pox in Ireland, and calling for returns of any cases which may have occurred throughout the country. In reply to this circular, the Commissioners received information relative to the existence of cases of small-pox in five unions. Two of these were traceable to England, and the other three had been produced by inoculation. The Board issued a further circular on the 7th of March, 1868, calling the attention of the guardians to these cases, and remarking—"Much as the guardians may be disposed to congratulate themselves upon this apparent approach to the extinction of small-pox in Ireland, the Commissioners feel bound to warn them that the continuance of immunity from this epidemic must depend upon continued activity in carrying out the provisions of the Compulsory Vaccination Act, and that even greater exertions than any yet made ought to be made to secure that end, inasmuch as there are many districts in which vaccination is not so thoroughly carried out as it should be, and some in which it has been very culpably neglected." This was most important advice and reasoning to those having the local administration of the vaccination laws. The advice seems, however, to have had but little effect, as infantile vaccinations diminished by 701, and vaccinations of neglected or previously vaccinated cases by 5,053 in the succeeding year. On September 20th, 1869, the Poor-law Commissioners again issued a circular announcing the cessation of small-pox in Ireland, and again warning the local vaccination authorities in the following words :—"Whether or not small-pox remains dormant in the country, and may be expected again to break out under less favourable circumstances, it is quite clear that every part of Ireland is at all times exposed to the introduction of the disease, either accidentally or by design, and, therefore, that the only security lies in a steady maintenance everywhere of the protective means afforded by vaccination." On Dec. 21st, 1869, the Poor-law Board issued a circular calling attention to the death of a Swedish sailor in the Hardwicke Hospital from small-pox, and to the occurrence of a case at Maynooth, arising either from this case or from a girl from the Royal Barracks, who was in the same hospital at this time, and also to a case in Belfast introduced from Liverpool. The circular concludes with another warning about the danger of neglected vaccination. This warning, together with the alarm created by the actual presence of small-pox, had a better effect than the previous circulars, and infantile vaccinations increased, but re-vaccinations continued to decline. Just about this time, on November 18th, 1869, Dr. Burke, Superintendent of Statistics at the General Register Office, now Registrar-General for Ireland, was examined before the Royal Sanitary Commission. In reply to the question, "Are you satisfied that that singular diminution in the amount of small-pox is owing to compulsory vaccination?" Dr. Burke said, "The diminution is very remarkable, but no epidemic of small-pox has occurred since the introduction of the Compulsory Act." Again, answering the question, "I presume that you do not go so far as to say that, owing to compulsory vaccination, small-pox has been stamped out in Ireland, or that it will be stamped out?" Dr. Burke said, "I should be very sorry to make use of such an expression. I think you should have the test of an epidemic in the country before you would use such strong terms." The test came very soon, and found how far small-pox was from being stamped out in Ireland. If others had been as far-seeing as Dr. Burke, and if accurate and complete vaccination returns had been frequently published and compared with the births, as they should have been, the susceptibility of the population of Ireland to small-pox could have been more easily and safely gauged than by the introduction of small-pox contagion. As I have pointed out, the circular of the Poor-law Commissioners, issued on the 21st of December, 1869, produced some results which were noted in the published returns for the year ended September, 1870; but the activity came too late, for small-pox had already sown its seed in Ireland, and a most destructive epidemic followed, which lasted for five years. The Poor-law Commissioners continued to issue warnings to the local authorities during the year 1870, and on December 15th announced a serious outbreak of the disease in Belfast. On February 7th, and again on March 2nd, 1871, the Commissioners called the attention of the local authorities to the importance of re-vaccination; and on July 13th, 1871, announced the appearance of the disease in 53 unions of Ireland. This, together with the increased prevalence of small-pox, had the desired effect, and at last, in 1872, vaccination and re-vaccination become sufficiently effectual to check the epidemic. In fact, the re-vaccinations by the dispensary medical officers in Ireland rose to the unprecedented number of 282,484, the births numbering but 149,292. Small-pox at once declined in all except

the remoter parts of the country, where it continued its progress for some time longer. In the Dublin district public vaccinations reached the immense number of 19,069, the births being only 8,499, in 1872. The complete vaccination and re-vaccination of the whole community seems to have immediately stamped out the epidemic. It is evident that it was the increase of re-vaccinations and the vaccination of neglected cases that stopped the career of the epidemic. As soon as vaccination fell very low—namely, in 1869—small-pox began to make its appearance, and grew into the terrible epidemic of 1872. In 1876 vaccination had fallen lower than it had in 1869, and immediately the present epidemic made its appearance.

In 1872 the Poor-law Board was converted into the Local Government Board, and all the sanitary powers in the country placed under its control. From this time forward it does not appear that the newly-constituted Board issued any circulars to the boards of guardians relative to the imperfections in the administration of the vaccination laws, although the annual reports of the Board refer to the neglect of infantile vaccinations. In the report for 1876-77 important circulars relative to lymph-supply are contained, and a long correspondence with the English authorities relative to the possible introduction of small-pox into Ireland through the agency of deported paupers. The omission to warn the local authorities in Ireland of the prevalence of small-pox in the towns in the north of England in daily communication with Irish ports, and of the appearance of small-pox in Dublin, seems to be a most unaccountable oversight on the part of the Board.

I cannot but think that had a circular been issued noticing a recurrence of the same circumstances that initiated the epidemic of 1871-73, and calling attention to the diminution of vaccination which had occurred in the year 1875-76, that the present epidemic might in some measure have been retarded and mitigated.

(To be continued.)

Clinical Records.

CASES IN PRACTICE.

By JAS. MARTIN, F.R.C.S., Portlaw.

In the Medical Press, August 1st, 1877, I reported two cases of rheumatic fever cured rapidly by salicylate of soda. I have since then treated four other cases, with exactly similar results. It would be useless to give their details individually; I will, therefore, state the points which struck me as worthy of notice. Each case had swollen painful wrists, elbows, and ankles; in one only the knees were swollen. The temperature ranged on my first visits from 102° to 104°. They were all sharp acute cases, with severe pain; all under six days from the time of first seizure. The medicine was given in half-drachm doses every four hours; all were literally cured on the third day after beginning its use. One, however, returning to his work on the sixth day in very bad weather, got a relapse, for which the salicylate did no good; but he quickly recovered under the use of the perchloride of iron with blistering fluid applied over the painful joints. This was the only patient whose heart became affected, but it was not seriously so.

In every case the medicine produced a profuse diaphoresis, during which I observed that the skin retained its tone, felt firm, though moist in a peculiar manner, as I also noticed in a case of different disease, which follows this. I have tried the salicylate in less acute cases several times, but did not obtain the slightest benefit. This fact was also noted and stated to me by a most respectable intelligent practitioner in the midland counties, as being the result of his experience before I had told him of mine. Thinking that the good effect of the salicylate might proceed from its great power of reducing temperature, I was led to try it in the following case of pneumonia:—

A. B, æt. 19, admitted to hospital Oct. 17, 1877, labouring under acute pneumonia of the right side. Dulness on percussion, extending over two-thirds of the right lung. Dry crepitating râle through the upper third. Pulse 120. Sputa bloody. Temperature 104-6°. He had got a wetting six days previously, followed by a chill and pain in right side. On admission got a diaphoretic mixture, and had a large poultice applied to the affected side.

Oct. 20.—Had a bad night; pulse, 120; temperature, 105°; no change in symptoms. I ordered half-drachm salicylate of soda every four hours, milk, tea, and broth.

Oct. 21.—Profuse diaphoresis set in during the night, the skin retaining the peculiar feel I noticed as occurring in some of the cases of rheumatism in which the drug had been prescribed; but there was no change in the pulmonic symptoms. Temperature, 102°. Continue medicine and poultice.

Oct. 23.—The patient has taken the salicylate steadily since last report; the skin firm, warm, and moist; temperature, 101°; the pulmonic symptoms have, if anything, become more intense, crepitation having set in in the lower part of left lung; sputa still deeply tinged; hard cough; pulse, 120, small and soft; urine abundant, high-coloured and clean; intermit salicylate of soda; continue poultice and nourishment.

Oct. 24.—Patient not so well; crepitation extends in left lung; the lower part of right lung solid; sputa still deeply tinged

I may wind up this case by saying that it was a prolonged and dangerous case, but ultimately made a good recovery. I could not, however, recognise any benefit as accruing from the use of this special drug, beyond the reduction of temperature, which never reached the same point again, though it rose to 103° before crisis set in.

Case of Congested Lung, relieved by Mercury.

This is no new story, but the use of mercury has gone so much out of fashion in later days in the treatment of lung disease, that I think the report of a case treated on the old-fashioned lines may be an encouragement to younger practitioners to have recourse to its use; while I would exhort them in doing so to remember that they are using a two-edged sword, and to be close and attentive in observing its action.

Oct. 12.—I was called to see a young woman of full habit, æt. 28, who was in a very prostrate condition after an attack of typhoid fever. She had hard hacking cough; a copious glary expectoration; pulse, 120, small and weak; profuse night sweats; the right lung perfectly solid from the base to the clavicle, and the lower part of left lung in same condition. I treated her for a fortnight with iodide of potass., in infusion of cinchona; iodine ointment externally; general support; Dover's powders at night, to relieve cough and check perspiration; but she made very slight amendment, if any. I then prescribed 1 gr. blue pill, 1 gr. quinine, ½ gr. of hippo, every four hours, and pushed it steadily on until the gums were well touched, which was about the seventh day. From the moment the white line formed on the gums on the fifth day, the extent of dulness under percussion began to decrease; the night sweats ceased, and the expectoration diminished. I kept on the pills at longer intervals for four days more, watching the mouth carefully, and then had recourse again to the iodide of potass. and infusion of cinchona. She gained strength rapidly; and after another month I could safely say she was in excellent health, though a little weak; and the dulness of the lung had completely disappeared.

An Interesting Case of Midwifery Practice.

On the 20th December I was called to see Mrs. W., in labour of her fourth child, at the third week after seven months of pregnancy. Labour was very violent, bringing the os uteri at each pain far down into the pelvis, though not dilated more than the size of half-a-crown. The edge was hard and rigid; the membranes protruded, but no presentation could be felt. I gave 40 grs. of chloral, and injected 1-3rd gr. acet. morphia subcutaneously into th

arm. The uterus relaxed a good deal after this, and dilated to about the diameter of two inches, but felt sharp and tense at the edges. Labour was not in the slightest degree interrupted. I now ruptured the membrane, and found that a shoulder presented; I at once prepared to turn, and had got my hand in the vagina, when I found the os so tense that I felt I would have great difficulty in getting my hand further. Mr. Barnes' instructions occurred to me, and as it was the left hand I had introduced I passed my right between the thighs, and placing my hand over the abdomen I found to my delight that I was able to seize the head, and while with my left I tilted the shoulder upward, thrust it into the pelvis. I then withdrew my hand, applied the short forceps, and terminated the labour in most satisfactory manner, the patient making good recovery. The child lived twenty-four hours.

Transactions of Societies.

DUBLIN OBSTETRICAL SOCIETY.

THE Sixth Meeting of the Session was held on Saturday, April 13th, 1878, the President, Dr. DARBY, in the chair.

TUMOUR OF LABIA.

Dr. MACAN said that for the recent specimen he was about to exhibit he was indebted to his colleague, Mr. H. G. Croly, and he thought it was of sufficient interest to justify his showing it. It was a tumour of the labia, and certainly—as far as he had been able to look up the subject—and he had not had much time to do so—he had found nothing corresponding to it. The patient from whom it was removed was a married woman, 30 years of age, who had been admitted into the hospital under the care of Mr. Croly. Five years ago she first noticed the appearance of the tumour, and since that time it had been gradually increasing in size. The tumour contained fluid, and hung from the upper part of the left labia. It was four inches long, and had a pedicle of about the same length. It was removed by means of an incision made between two ligatures, and there was no hæmorrhage. The peculiarity of the tumour was that it hung from the upper part of the left labia. The exact nature of it he was rather at a loss to know. It did not appear to be a fluid tumour, because it contained solid matter at the bottom of it. It was almost like a hydrocele.

The PRESIDENT said the tumour was a very interesting one, and was not, as far as his experience went, common. He had seen two cases of the kind, one at Steeven's Hospital, under the care of the late Dr. Hardy, in which the pedicle was ten or twelve inches long. It hung down nearly as far as the knee. That tumour was not quite so large as the present specimen, but it was partly fluid. When it was felt it gave the sensation of being a bag of worms. It was removed by the écraseur by Dr. Hardy. About six years ago Dr. Symes, of Kingstown, asked him to see a similar case in which the tumour had a pedicle the same as in Dr. Macan's specimen. That also was removed by the écraseur, and the case did very well. Had he (the President) been called upon to operate in the case now before the Society, he thought he would have used an écraseur too.

PUERPERAL CONVULSIONS.

Dr. PUREFOY then laid before the Society the details of two cases of puerperal convulsions, in which the hypodermic injection of the hydrate of chloral was successfully used. He said the value of the medicine in such cases was now universally admitted; but in this country, as far as he knew, it had hitherto been given only by the mouth or rectum. His first patient was aged 18 years, and had been subject to fits from the early age of five. At first they occurred at long intervals, but as she grew older they greatly increased in frequency and severity. In January, 1877, she had seven consecutively, and in the month of April following, she had eleven in one day. About that time, though still unmarried, she became pregnant, and fretted very much in consequence. For two days before her confinement he was informed she had not taken any solid food whatever. At the time he saw her a small putrid fœtus had been expelled without any loss of blood. She was then suffering from the fits, which occurred at only a few minutes' interval between each. He at once sent for some chloral, but in the meantime commenced with the chloroform treatment. Subsequently he injected five grains of chloral in the thigh. At that time the pulse was 144, and the temperature 100°. The subsequent seizures were of only brief duration, lasting for 30 to 60 seconds, instead of, as before, three or four minutes. He administered further five-grain doses at intervals until he had given in all 25 grains. The second case—similarly treated—occurred in the Rotunda Hospital, and the convulsions took place after delivery. In both cases the treatment was begun by giving chloroform. His reason for that was, in the first place particularly, the convulsions were very frequent and severe, and using chloral in that way he was to a certain extent experimenting, because it was the first time he had used it; but the effect of the medicine was very marked indeed in both cases.

Dr. MACAN said the Society was much indebted to Dr. Purefoy for bringing the cases forward, for unquestionably the treatment was new. On looking over some American papers, however, he saw that Dr. Richardson, formerly a pupil in the Rotunda Hospital, had also used the hydrate of chloral. The objection found to it was that it caused abscesses to form at the seat of injection, but Dr. Purefoy seemed to have avoided that by using a weak solution, and injecting further down the cellular tissue. He was sorry, in the cases detailed by Dr. Purefoy, that there was any use of chloroform, which somewhat confused the results that might otherwise be attributed to chloral. He thought in the first case that the effects would be doubtful because the girl was the subject of fits from her childhood, and there was no albumen in the urine, two of which circumstances made him doubt very strongly—though he did not pretend to explain the case—that that was an ordinary case of puerperal convulsions, for it appeared to be mixed up with epilepsy. The other case was not a fair one to judge by, because the convulsions did not arise until after the woman had been delivered, and the patient might have got well without any treatment. At the same time he considered the method of treatment most useful, especially in those cases where they wanted a quick effect to be produced; and if he had a case of puerperal convulsions to-morrow, he would give the chloral a trial.

Dr. MORE MADDEN said the paper that had just been read was one of great importance, and he thought Dr. Macan's observations were also very interesting. He would not for one moment accuse either Dr. Macan or Dr. Purefoy of reading a paper of his, but at the same time he might state that ten years ago he read a paper to the Dublin Medical Society, and was the first person who wrote a paper on the subject of the administration of hydrate of chloral at the time Liebreich first brought it out, and in it he (Dr. More Madden) dwelt at great length on the administration of hydrate of chloral in puerperal convulsions, in which he gave it a very fair trial, and in which he found it ineffectual. He thought it right to state that, because Dr. Macan had said that if he had a case to-morrow he would give it a trial. If the case were one of mere hysterical convulsions, it would get well of itself, whether chloral was administered or not; but if in a case of true puerperal convulsions he wasted his time trying hydrate of chloral while the patient was dying he (Dr. More Madden) thought the death of the patient would really be in great measure attributable to the waste of time in using a treatment which experience had proved to be ineffectual. He thought if the experience of those who had given the remedy a fair trial—tried it largely, on an extended scale in bold doses, and found it to be ineffectual—if that experience, gained no matter by whom, was to be utterly ignored and passed by, and other gentlemen came forward and started it again as a new thing, a great deal of injury would be done to unfortunate women who were lying wasting while these experiments were being tried over again. They had a tolerably certain way of curing puerperal convulsions, and were they to disregard that and to try experiments in the most serious disaster that could arise to a pregnant woman—to spend their time trying experiments with hydrate of chloral and other absurd remedies of that class, simply because they had not made themselves acquainted with the literature of the subject?

Dr. MACAN said he must have badly expressed what he wished to convey. He was perfectly well acquainted with the literature of the subject, and he was perfectly well aware that chloral was one of the most received treatments of puerperal convulsions at the present time.

Dr. M'CLINTOCK had no experience of the value or utility of chloral as a remedy in the treatment of puerperal convulsions. He dared say it had its proper place, and there might

be cases in which it would be serviceable. But he must say in all candour that he did not see that Dr. Purefoy's cases would justify any inference as to the value of chloral in the treatment of eclampsia. It was doubtful whether the first case, which remained for some days in a critical state, was one of puerperal convulsions at all, because the convulsions occurred at a period of pregnancy when true eclampsia very seldom appeared. He did not think they should attribute that patient's escape to the influence or efficacy of chloral. With regard to the other case, he did not think they could venture to say that chloral had any very decided influence one way or the other. The convulsions occurred after delivery, after the patient was brought to hospital, and she there underwent other modes of treatment. At the same time Dr. Purefoy's paper was new and interesting, as it showed that the chloral might be administered hypodermically without any unpleasant effects, either constitutional or local, and that was of some value. And if he (Dr. M'Clintock) had a bad case of convulsions that resisted other treatment, and the symptoms were severe, he would certainly feel justified in trying a large dose of chloral subcutaneously. He must, however, say with Dr. More Madden that there were other modes of treatment which he certainly should put in practice before he tried the chloral.

Dr. DENHAM said they must never lose sight of the variety of causes that might induce puerperal convulsions, and the variety of results arising from those causes. When a young plethoric woman came into hospital with a rapid pulse, flushed face, constipated bowels, and a variety of other symptoms, it was quite clear that the treatment should not begin with chloral. There were broad principles laid down for the treatment of convulsions which must first come into operation, and he did not hesitate to say that he was not ashamed to own that in a case such as he had spoken of, he would not hesitate to take out his lancet and take a good dose of blood from the arm. He would also relieve the bowels. Those two points having been gained, he would pave the way for an anæsthetic, such as had been spoken of, or by the administration of chloroform. He thought the effect would be much the same, except that there would be this advantage, that the chloral would act more rapidly. When he was at the Rotunda Hospital he remembered carrying out a series of experiments—before chloral was known—with chloroform, and in some cases it diminished the number and severity of the fits, but in others he had seen the convulsions go on under the influence of chloroform. They must never lose sight of the fact that two swallows did not make a summer, and so in like manner ten cases of convulsions treated in any particular way would not warrant a change for the old standard modes of treatment; and without having the slightest doubt that the treatment was judicious in Dr. Purefoy's hands, he (Dr. Denham) agreed with Dr. M'Clintock in thinking that neither of the cases were what they would formerly call regular cases of eclampsia. With reference to one remark of Dr. Macan's, that convulsions after delivery were less serious than those occurring before delivery, he wished to say that his (Dr. Denham's) experience was rather different to that. He would look with much more apprehension upon a woman attacked with convulsions after delivery than he would on a woman who was similarly attacked before delivery.

Surgeon-Major JOHNSTON mentioned a peculiar and interesting kind of convulsion that he once witnessed a few days before the woman's confinement. On going out of the lying-in ward of his own hospital, he met the husband of one of the patients, and told him that his wife was in severe convulsions. He immediately commenced to rub his hands with much satisfaction, and said, "Oh, doctor, don't do anything to her, and she'll have a baby in three days." He (Dr. Johnston) gave the woman no treatment, and true enough exactly at the end of three days she gave birth to a child. That had occurred in that woman's case on several previous and successive occasions.

Dr. PUREFOY, in reply, said that he thought he was right in saying that the absence of albumen in the urine did not prove that the case was not one of puerperal eclampsia. His second case was not a severe one, but he had seen convulsions last for two days after delivery. At the same time he thought convulsions occurring after were not so serious as those occurring before delivery. He must plead guilty to not having read Dr. More Madden's paper on the use of chloral, and was not aware whether he had spoken of using it subcutaneously. But notwithstanding Dr. More Madden's extensive experience, he (Dr. Purefoy) thought the value of chloral had been proved by other observers quite sufficient to justify practitioners in continuing its use. He (Dr. Purefoy) spoke from tolerably good experience, having spent three years at the Coombe Hospital, and subsequently three years at the Rotunda Hospital, where he had had opportunities of testing, and of seeing tested, the different modes of treatment. He brought these cases forward because they showed that chloral might be used without the production of abscesses, and he was greatly impressed with the benefit of the medicine in the first case.

The Society then adjourned.

SOME RESEARCHES ON MORBID LOCAL TEMPERATURE. (a)

By MICHEL PETER, M.D.,
Professor to the Faculté de Médecine, Paris; Physician to the Saint Antoine Hospital, &c.

IN giving the result of a long series of investigations I have made on morbid local temperature, I shall in this first communication speak of the temperature of the *thoracic walls in cases of pleurisy*, and its variations from certain determined conditions, as well as its relation with the mean normal temperature, and with the parietal temperature on the healthy side. To establish these facts, I placed the same thermometer in the same intercostal space—the sixth, for instance—on the diseased and on the healthy side, then in the axilla on the healthy side, using the ordinary medical thermometer, so that practitioners might be able to compare and continue such experiments.

The investigation of local morbid temperature is not a scientific curiosity: it has a clinical and useful application, as, for instance, it may clear up and even fix the diagnosis in doubtful cases of incipient pulmonary tuberculosis. It may yet serve to elucidate certain abdominal affections, oftentimes so obscure.

Some of my results were as follows:—

1. On the pleuritic side the parietal temperature is always higher than the mean temperature, which is 35° 8 C. (96°·4 Fahr.)

The morbid increase or local hyperthermia is 1°, 1°·5, 2°·5 and even over this figure; the local temperature reaching 38° (100°·4 F.), 39° (102°·1 F.), and even 40° (104° F.)

2. The elevation of temperature increases with the effusion, that is to say, the greatest elevation of local temperature corresponds to the period of active secretion of the inflamed pleura; this hyperthermia varying from 2°·5 to 3°.

3. The elevation of the parietal temperature increases when the secretion is arrested. In general the parietal temperature of the pleuritic side exceeds that of the healthy side by 5°·10 to 1°·5.

4. Pleurisy not only affects the parietal temperature of the affected side, but also of the healthy side, though the affected side has always a higher temperature.

5. The parietal temperature lowers little by little when the effusion is absorbed spontaneously, always remaining higher than the opposite side, preserving for some time this exalted condition. This temporary persistence of the local hyperthermia is not to be neglected, as it explains the possibility of a return of the affection, indicating the persistence of the anatomical conditions affecting the formation of the effusion.

6. In cases of pleurisy without effusion (diaphragmatic, for instance), the local hyperthermia is less than in cases with effusion, and the return to a normal condition is made more rapidly.

Thus, in a recent case of diaphragmatic pleurisy—treated and cured by the application of wet cupping and a vesicatory—the highest parietal temperature was 37° (90°·3 F.), (in place of 35°·8, the normal state), and a return to the 35°·8 was obtained in eight days.

On the other hand, in a case of pleurisy with considerable effusion, complicated by pneumonia which developed in the course of the disease, the parietal temperature reached 40°·8 (105°·4 F.), the axillary temperature being only 40°·2; and the return to the normal parietal temperature took place in twelve days.

(a) *La France Médicale*, May 4th, 1878.

7. One of the most interesting facts, perhaps, is, that the absolute elevation of local temperature on the affected side is more considerable than the absolute elevation of the axillary temperature, although the thermal axillary figure may be higher than the thermal parietal figure. The local precedes the axillary hyperthermia. For instance, in one case the parietal hyperthermia was 2°·8, the axillary being only 1°·6; in the evening the parietal reached 5°, the axillary only 3°·2.

The excess of local over general hyperthermia was thus 1°·2 in the morning, 1°·8 in the evening.

These facts relate to pleurisies which have not been operated on, and we have next to consider the same condition when punctured.

8. On evacuating the effused liquid, emptying the cavity of the pleura, an unexpected phenomenon is produced—*the parietal temperature rises on the punctured side.*

One of three results may then happen —

a. The effusion may not return.

b. It may recur.

c. It may return, changing its nature.

a. If the effusion does not return, the parietal temperature (which before puncture was more elevated than normal, and than the healthy side) may still rise; but this increase only lasts some hours (24, 36, or 48). Then the parietal temperature decreases, returns to the figure before puncture, then decreases still more, and finally returns to the normal condition.

*b*1. The effusion may increase and then be absorbed.

In the period of new secretion, the local temperature rises, very notably after puncture, remains hyperthermal for some days, then decreases under the influence of medicine, returns to the figure before puncture, and finally to the normal state. It is remarkable that the local hyperthermia precedes and exceeds, morning and evening, the axillary hyperthermia, and the local lowering of the temperature proceeds the lowering of the axillary temperature.

*b*2. The effusion may recur, and repuncturing may be required. Then we have local, next general hyperthermia; stationary state of the local temperature, with reproduction of the effusion; repuncture with reproduction of the same thermic and secretory phenomena.

c. It yet remains to determine the parietal temperature, in cases where effusion takes place, under a purulent form, and I propose to undertake it as soon as I have an opportunity, which has not yet presented itself.

These facts would be of little value if we did not examine their mechanism, signification, and their possible practical utility.

One intrepretation naturally presents itself to the mind; viz., that the elevation of local temperature after thoracentesis results from the return of the functions of hæmatosis to the lungs.

Another interpretation is, that the elevation is due to traumatism from puncture of the inflamed pleura.

It is easy to refute this double interpretation by reason, and far better by experiment. By reason, for hæmatosis is never as immediately so complete on the punctured side as on the healthy side, so that the temperature ought to be lower on the diseased side. By experiment, by eliminating from the problem, hæmatosis and phlogosis, as I have done in examining the temperature after puncture of the abdomen, in cases of ascites, where there is neither hæmatosis or phlogosis to interfere. Now the local temperature always rises in cases of ascites, the elevation of temperature is almost immediate, and almost immediately at its *maximum*. But —

1. The difference goes on decreasing from day to day in ascites.

2. The abdominal parietal temperature returns in a few days to its natural state before puncture.

3. The temperature does not undergo any diurnal or nocturnal change.

4. It follows the hypercrisis, increasing or diminishing with it.

5. And this fact is important; however elevated the abdominal temperature is after puncture, the axillary temperature is invariable, that is to say, it is never influenced by the local change of temperature. We have in effect in one case, a physical fact, the extravasation of liquid; in the other, phenomena of secretion and selection—a chemico-dynamic fact.

The conclusions then are :—

1. That local hyperthermia, the result of puncture in pleurisy, as well as in ascites, is the consequence of hyperæmia *a vacuo.*

2. That in cases of pleurisy, this hyperæmia, essentially mechanical, necessarily adds to the previous hyperæmia and phlegmasia, against which puncture has been absolutely without curative action.

3. That we thus have two hyperæmic conditions, in place of one.

4. That there necessarily results an augmentation of tension in the vessels of the still inflamed pleura.

5. That thus on the one hand, the liquid exuded afresh may be richer in leucocytes and hæmatites.

6. That there is a dynamic action, and that the possible purulent transformation of the effusion, occurs in certain cases where puncture has been adopted during the very febrile period of pleurisy.

7. That this accumulation of hyperæmia, this return of the blood into the pleural cavity, marked by the local hyperthermia, explain the syncope, the pulmonary congestion, the consecutive albuminous expectoration, the pain and the oppression running sometimes to suffocation, observed in many of the cases, to the elucidation of which I have contributed by my researches on local hyperthermia.

WEDNESDAY, MAY 15, 1878.

BLOOD-LETTING IN PUERPERAL CONVULSIONS.

About twelve months ago we drew attention to the fact of there being some signs that this old-fashioned and almost obsolete remedy would again come into use, although of course not to the extent to which it was formerly employed, for it is only under special circumstances or in certain exceptional cases that we should venture to recommend the practice of general blood-letting. Among those practitioners who still think that with regard to this practice we have gone from one extreme to the other may be mentioned Dr. J. G. Swayne, Consulting Physician-Accoucheur to the Bristol General Hospital, whose experience of blood-letting in the treatment of puerperal con-

vulsions certainly justifies the confidence which, in certain cases, he places in this remedy. He has from time to time brought forward his cases at the meetings of the Bath and Bristol Branch of the British Medical Association, and in the current number of the *Obstetrical Journal* is recorded one case in which the withdrawal of ℥xxx. of blood in a full stream from a large orifice was followed by immediate and permanent relief of all the symptoms. The convulsions had gone on for twelve hours before bleeding was resorted to. They had increased in frequency, until at last as many as three took place in an hour, notwithstanding that a full trial had been given to anæsthetics, in the form of hydrate of chloral and bromide of potassium, three half-drachms of the former and three drachms of the latter having been given. The bleeding appeared at once to produce a decided constitutional effect. The swollen livid face became pale, the breathing less stertorous, and the pulse soft and feeble, instead of full and throbbing. From that time the fits, which were recurring three times in an hour previously, only returned four times during the next ten hours, and were much mitigated in severity. Signs of labour also came on, and delivery was soon completed with the forceps. Dr. Swayne's experience of puerperal convulsions comprises thirty cases. In twenty-two of these bleeding was resorted to, the quantity of blood varying from ten to thirty ounces. In sixteen it was decidedly beneficial, and appeared to be the most efficacious remedy employed. In nearly every case it was speedily followed by a great diminution in the amount of albumen contained in the urine; and to this cause Dr. Swayne believes that blood-letting owes its great power as a remedy.

If the experience of Dr. Swayne were the only evidence in favour of our occasionally resorting to the lancet in the treatment of this terrible complaint, we should not perhaps have drawn particular attention to it. But it should be borne in mind that this was long the orthodox plan of treatment, and that even at the present day the occasional use of the lancet is recommended by high authorities both in this and other diseases. All the great accoucheurs who practised in the beginning of this century were unanimous as to the utility of bleeding in puerperal convulsions. As late as 1855, we are told in one of the most popular text-books of obstetric medicine, to take away blood from the arm or temporal artery, largely, and in a full stream, provided the convulsions are of a sthenic form, with the head hot, face flushed, and the pulse full, firm, and frequent. We are even told to repeat the blood-letting if the paroxysms continue. Prof. Depaul even ventures in 1877 to say that copious bleeding from the arm is the only method of treating the disease which meets with success, and refers to an experience of two hundred and fifty cases in support of his opinion. Moreover, in respect of other diseases not more likely to be benefited by venesection than puerperal convulsions, there are some eminent authorities who are by no means so ready to wholly discard the use of the lancet as is now the case with the profession in general. In the volume of Ziemssen's "Cyclopædia of the Practice of Medicine" devoted to the consideration of Diseases of the Brain and its Membranes, we find that Nothnagel is by no means averse to the employment of blood-letting in certain forms of cerebral hyperæmia, or even apoplexy. Speaking of hyperæmia, he says that "the evidence afforded by the diminution in the severity of the symptoms, which follows, for example, an accidental nose-bleeding, seems to point too clearly to the propriety of this treatment; under certain conditions we could not get on without it." General indications, he remarks, for the use of the lancet are furnished by the presence of marked *turgor faciei*, strong cardiac impulse, and abnormal fulness and tension of the arteries. The same writer in speaking of the practice of blood-letting formerly universally adopted, and now almost as universally abandoned, in the treatment of hæmorrhagic apoplexy, very judiciously observes "that the true path which is followed by the majority of good practitioners lies evidently between the two extremes." The value of venesection in cases of cerebral hæmorrhage lies, in the opinion of Nothnagel, "in the fact that it brings about a diminution of the intra-cranial pressure (*i.e.*, indirectly, of course, by diminishing the arterial tension), and in this way its influence may be at times of capital importance. Where, in consequence of the intra-cranial pressure, and of the cerebral hyperæmia that accompanies the attack, paralysis of the respiratory or of the vagus centre is threatened, the rapid reduction of the quantity of the circulating blood may, by diminishing this pressure, have the effect of actually prolonging life, and this indication can only be fulfilled by venesection." We have made the above quotations not only because Ziemssen's "Cyclopædia" is justly considered to be the most recent and most authoritative exposition of modern medicine, but because the above observations are far from being inapplicable to some forms of puerperal convulsions. It will be generally admitted that in many cases of this affection we have present those conditions which, in the opinion of Nothnagel, justify the use of the lancet—intra-cranial pressure, great arterial tension, congestion of the cerebral vessels, impeded return of the blood through the cerebral sinuses, overloading of the blood with carbonic acid gas, &c. These conditions are particularly prominent in the worst cases of the epileptic form of puerperal convulsions, as well as in those cases which are more of an apoplectic than of an epileptic nature; and although it very rarely happens that the disturbance in the cerebral circulation gives rise to actual extravasation of blood, the effect of that disturbance upon the brain and medulla oblongata is such as to predispose the system to a repetition of the convulsive paroxysms, and to the persistence of that comatose condition the removal of which is one of the chief indications in the treatment. Owing to the age at which these convulsions generally occur, the coats of the cerebral vessels will bear a great deal of tension, and effusion into any part of the brain rarely takes place, yet sometimes this accident does occur, and at the meeting of the Dublin Obstetrical Society, Dr. Denham mentioned a case in which cerebral hæmorrhage was found after death, and in which he thought life might have been saved if the patient had been bled early in the convulsions.

In the foregoing observations we have merely mentioned one way in which bleeding may prove useful in the treatment of puerperal convulsions, but as respects this disease more especially, there is another light in which we may view the *modus operandi* of blood-letting, and which shows that

this remedy may be found useful in other convulsions than those which occur in connection with childbirth. As we have just seen, Dr. Swayne attributes the efficacy of bleeding in puerperal convulsions to the effect it had of diminishing the amount of albumen contained in the urine ; and the truth of this opinion is strongly corroborated by the result which has followed the treatment of a number of cases of uræmic convulsions and scarlatinal dropsy by copious venesection. Some of those cases will be found detailed by Dr. Robert Kirk, in the May or June number of the *Glasgow Medical Journal*, 1877, and others by Dr. Bramwell, of Perth, in the *Edinburgh Medical Journal* for July, 1875. In Dr. Kirk's cases the convulsions were severe, other means had been tried in vain, the convulsions ceased immediately after the bleeding, and the urinary secretion was restored, with or without the use of diuretics. For example, a girl aged nine, was comatose after scarlatina, with puffed, pallid face, teeth clenched, a little foaming at the mouth, pulse 140, pupils moderately contracted and insensible, and rapid oscillation of the eyeballs. The case appeared a very unfavourable one, but about twelve ounces of blood were drawn from the arm, and in four or five hours afterwards the pulse had fallen from 160 to 80, she fell into a natural sleep, and ultimately recovered. In every case in which Dr. Kirk tried blood-letting in scarlatinal dropsy, the treatment proved eminently successful ; while in thirty-two cases of the same disease in which Dr. Bramwell had recourse to general abstraction of blood, there was only one death, and that a case which was seen too late for treatment to be of any service. Amongst his cases were some of both pulmonary œdema and convulsions, and he also found that free diuresis set in forty-eight hours or less after blood-letting.

These facts, and we might have mentioned others of a still more striking nature, taken in connection with those that have been adduced by Dr. Swayne and other practitioners, must convince the most sceptical mind that, in properly selected cases, blood-letting is far from being such a perilous or useless remedy as many are now-a-days led to suppose, and that puerperal convulsions is not the only affection in which the judicious employment of that remedy may, under certain circumstances, be followed by the most beneficial results. At all events, the experience of those physicians to whose opinions we have just drawn attention, and the well-balanced judgment of so recent and eminent a writer as Nothnagel, are sufficient to inspire the young practitioner with some confidence in this remedy whenever he meets with cases in which a fair trial of it appears to be particularly indicated.

RECENT CASES OF POISONING AND THEIR DETECTION.

Two cases of poisoning have recently occurred, one in Scotland, the other in Paris, which are quite sufficient to show any one contemplating such a crime, that be his scheme ever so skilfully contrived he is almost certain to fall sooner or later within the clutches of the law. If science has rendered it *possible* for a murderer to poison his victim in such a manner as to escape detection, science has also pointed out the means by which, in 99 cases out of 100, the crime will certainly be discovered. The poisoner Chantrelle, who has just been condemned to death for the murder of his wife, had boasted that he could poison her in such a manner that all the faculty would not be able to find it out ; but it so happened that the way in which he set about his horrible business, and the way in which he tried to conceal it, would have been a bungling procedure for the most ordinary and ignorant criminal, much more so in the case of a man who is said to have been educated for the medical profession, and who was supposed to know a good deal about the chemistry and operation of drugs.

Our contemporary, the *Observer*, in commenting upon this case, compares it to the notorious Palmer and Pritchard poisonings, and says that Chantrelle, like Pritchard, was a physician, with a considerable knowledge of toxicology. This we are in a position to contradict. Certainly if Chantrelle ever practised medicine he did so illegally, not being a registered practitioner.

The facts of the Edinburgh poisoning case must be so familiar to our readers that it will be unnecessary to recapitulate them. The medical evidence clearly pointed to death by narcotic poisoning. There were present the chief symptoms observed in cases of poisoning by opium ; and the fact that these symptoms varied a little from those usually observed in these cases did not in the least weaken the evidence against the prisoner, for, as Prof. MacLagan was obliged to admit, there was no such thing as invariableness in the action of any poison, nor could anything be made of the fact that no trace of opium could be found in the body of the deceased. Not only is it very difficult to detect in the body the presence of organic poisons, but in this case the prisoner had evidently contrived to give his victim a minimum poisonous dose, so that it was not likely that any remains of it would be detected in the contents of the stomach. The attempt to account for the death by gas-poisoning was a very miserable and hopeless one ; for not only are the special signs of opium-poisoning very different from those produced by the inhalation of gas, but the latter is a poison which, if allowed to escape in quantities sufficient to destroy life, is perceptible to the senses of the other inmates of a house.

The other case, which occurred in France, may not be so familiar to the reader.

Here the prisoner, was certainly familiar with the operation of poisons, for he was a chemist living in the Rue Maubeuge. His wife, whose married life had been a very unhappy one, became ill, and appeared to be wasting away : medical aid was of no avail, and she died rather suddenly last September. A *post-mortem* examination led to Danval's arrest on the charge of slow poisoning by arsenic, but two leading analysts subsequently gave an opinion that the arsenic found in the viscera was insufficient to cause death, and might have resulted from natural causes. On the other hand, it is urged that the deceased's symptoms—viz., burning pain in the stomach, parched and stiffened tongue, and almost paralysed legs—can only be accounted for by small doses of poison such as would leave few traces, and that no organic disease could be detected. The accused, who waited on her in her illness with great apparent sympathy, first endeavoured to get her disease ascribed to typhoid fever, and afterwards suggested suicide—a suggestion held to be negatived by her amiable

and religious character. The trial lasted several days, and the prisoner was found guilty of murder. In this case the criminal had some chance of being acquitted on the grounds of the quantity of arsenic found in the body being very small, but as there was no other way of accounting for the presence of even a small quantity of that poison in the viscera, as the symptoms were just those which are generally observed in chronic poisoning by arsenic, while they could not be accounted for by any morbid appearances arising from natural causes, the evidence against the prisoner was, on the whole, very conclusive. With regard to the skill and secrecy with which these murders were committed, they will scarcely bear comparison. Chantrelle's crime was a very clumsy and ordinary case of poisoning by opium; whereas that of Danval, cruel and villainous though it was, was conducted with all the art of a professional expert. There are, moreover, not many cases of chronic poisoning of arsenic on record, and, therefore, the one which has lately excited so much attention in Paris is, in a medico-legal point of view, both an interesting and instructive one.

Notes on Current Topics.

The Registrar-General's Quarterly Return.

THERE are a few facts in the last quarterly return of the Registrar-General to which we would draw the attention of the reader. In the first place, one effect of the commercial depression that has lately prevailed is a decline in the marriage rate. This rate for the entire year 1877 did not exceed 15·8 per 1,000, and was lower than the rate in any year since 1847, when the rate was equally low. Owing to the mild winter we have this year experienced, the annual rate of mortality during the first three months of the year has been unusually low. It was 22·8 per 1,000, or 1·2 per 1,000 below the average rate in the corresponding period of the ten years 1868-77. In South Wales great distress has prevailed in consequence of strikes and general depression in the coal and iron trades; and there the death-rate was equal to 25·3 per 1,000, against 22·9 and 2·8 in the corresponding quarters of 1876 and 1877. In Lancashire the returns do not seem to satisfy the Registrar-General, for he remarks that 8,569 persons died in that county who would have survived if its sanitary condition had been equal to that which prevails in Westmoreland. The waste of life in Lancashire affords conclusive evidence of unsatisfactory sanitary condition. In twenty of the largest English towns, including London, the death-rate was rather high—25·2 per 1,000—owing to the greater fatality of the seven principal zymotic diseases, more especially of measles and whooping-cough. In fact, whooping-cough was the most fatal zymotic disease last quarter, and caused 5,216 deaths, against 3,971 and 2,533 in the corresponding periods of 1876 and 1877. It is satisfactory to notice that the steady and well-marked decline in the deaths referred to fever in recent years is fully maintained. The death-rate from fever last quarter was less than half what it was in the corresponding period of 1870. The deaths from fever in England and Wales last quarter, at the rate which prevailed in the first quarter of 1870, would have been 4,596, instead of the 2,174 actually recorded. In addition to this saving of 2,422 deaths from fever, it may be calculated that more than 12,000 persons were spared attacks of fever during these three months, through the improving sanitary condition of the country.

We have in this report some curious information respecting the *certification of causes of death*. The number of deaths registered last quarter was 139,825. The causes of 125,841, or 90 per cent., of these deaths were certified by registered medical practitioners. In 7,199 cases, equal to 5·1 per cent. of those registered, no certificate of the cause of death was produced. It is evident, however, that the number of uncertified deaths is yearly decreasing. The largest proportion of uncertified deaths consists of cases in which the deceased persons have been attended in their last illnesses by unqualified practitioners, practising either on their own account or as assistants to registered practitioners; although in some thinly populated parts of England and Wales considerable numbers of persons die without any kind of medical attendance in their last illnesses. The following are examples of the replies made by registrars to inquiries as to the reason why so large a proportion of the causes of deaths in their sub-districts last quarter was uncertified. A registrar of Durham says, "The medical officer of the collieries resides several miles from the place, and keeps a non-registered assistant who attends all those cases, who gives information as to the cause of death." A Chesterfield registrar says, "It is in consequence of Mr. ——, a druggist, attending so many young children in sickness, and others as well, he being much thought of among the working classes."

Mr. Bright on Vaccination.

THE RIGHT HON. JOHN BRIGHT, who has considerable influence with the masses, having on more than one occasion spoken somewhat equivocally of vaccination, has been somewhat severely handled in the press by supporters of law and order, who naturally condemned the policy of an ex-cabinet minister, which encouraged the public to break the law. Accordingly, Mr. Bright wishes to put himself right with the public, and in the *Pall Mall Gazette* of Thursday last we find the following:—

"I observe in your paper of to-day a paragraph misrepresenting and condemning what I have written on the subject of vaccination. I have expressed no opinion against the practice of vaccination, but have always said that the facts, so far as I have been acquainted with them, appear to be in favour of it. I do not know that I have expressed an opinion adverse to compulsory vaccination, although I may have great doubt as to its wisdom in cases where parents are opposed to it. What I have condemned is the repeated punishment by fine or imprisonment of parents who are convinced that vaccination is often injurious and sometimes fatal, and who have had experience of its mischief, and who therefore refuse to have their children vaccinated. I think it is a monstrous invasion of the right of parents thus repeatedly to punish them; and, further, that it excites much greater opposition to the practice of vaccination than would otherwise exist. If the law is right and wise, why does it not take the child from the arms of its mother and force the vaccination upon it? Doubtless because the outrage upon the parent would be so great that Parliament shrinks from doing it. It insists upon the parent doing what he, in some cases, believes to be mischievous, and sometimes fatal, and what,

therefore, in conscience, he cannot and will not consent to do. If only one moderate fine were imposed, the parent would not become a martyr, and vaccination, in my opinion, would be less strongly objected to than it is now."

Chrysophanic Acid Ointment in Psoriasis.

PROFESSOR NEUMANN, the eminent dermatologist of Vienna (*Weiner Mediz Presse*, No. 14-16, 1878) having made extensive trials with this ointment at the General Hospital, Vienna, in the treatment of psoriasis, as first recommended by Mr. Balmanno Squire in this country at the latter end of 1876, is very favourably impressed with the results.

After giving due credit to Mr. Squire, and to the other English observers who followed him in this research, the Professor winds up an able paper with the following summary :—

1. That chrysophanic acid derived from goa-powder is an excellent remedy for herpes tonsurans, pityriasis versicolor, and psoriasis vulgaris.

2. Psoriasis in its earlier stages begins to disappear after a few applications of the drug, and in a far more unequivocal manner than under any other remedy that has ever yet been used against psoriasis.

3. Even inveterate forms of the disease can be abolished by means of chrysophanic acid, and it is quite the exception to find them oppose any protracted resistance to it.

4. Chrysophanic acid is a perfectly painless application to the diseased skin. The morbid phenomena occasioned by it on the healthy skin result apparently from the admixture of resinous matter with the acid.

5. As a result of this mode of treatment psoriasis belongs no more to those skin diseases which in so high a degree are a source of misery to the patient, and it has now become an easy matter to cure relapses. Every patient with psoriasis that I have as yet treated by this means gives the palm, without hesitation, to this method of treatment in preference to others. In any case, this, at the least, is emphatically true, namely, that the therapeutics of skin diseases have for the last ten years been enriched by but few remedies which have been crowned by so eminent a success as the one in question.

6. There are other skin diseases also which are curable by chrysophanic acid, but upon these I will not report until I have accumulated more material.

7. Lastly, I desire to express a hope that this method, which I am the first to promulgate in this, my country, may be examined by other observers, and I do not doubt but that it will soon permanently assume its due rank amongst the treasures of therapeutics.

Infant Mortality.

THE death-rate of infants in Macclesfield has given occasion for a very warm discussion in the local papers arising out of alarming statements made by the local medical practitioners at an inquest. A committee was appointed to investigate the matter, with the following results. "The evidence adduced before the committee," says the report, "failed to justify the charge of criminal neglect and child murder, 'but showed without doubt that the infant death-rate of Macclesfield is considerably in excess of the average throughout England,' and 'strongly impressed' the committee 'with the fact that the causes of the excessive infantile mortality are preventable.'" These are tabulated as follow :—1. To the lack of maternal care of children, arising from mothers returning to their work too soon after confinement. 2. To improper feeding and exposure. 3. To the too frequent use of narcotics and soothing medicines. 4. To the ignorance and negligence of parents in seeking promptly the advice of qualified medical men when their children are first taken ill. 5. To constitutional and hereditary causes arising from immorality of parents, &c. 6. To lack of personal cleanliness in neglecting the daily washing of children ; and 7. To residence in unhealthy and ill-ventilated houses. To the above may also be added an over-indulgence in drink by the parents. The committee suggest—1. That mothers should be restricted from working for a limited period before and after confinement. 2. That *crèches* or nursing houses be established under medical inspection, and visited by ladies committees. 3. That the sale of narcotics and injurious soothing drugs should be limited. 4. That a more rigid inquiry should be made into the cause of uncertified deaths, and medical evidence taken. 5. That all available means be taken to enlighten ignorant and careless parents as to their responsibilities and duties, and that Dr. Lankester's "Plain Rules for the Management of Infants" be distributed constantly.

Examinational Traps.

THE examiners in preliminary education for the English Pharmaceutical Society, in reporting to the College of Preceptors, say that it has sometimes been exceedingly unsatisfactory to have to award to a candidate for his perfect translation of the passage from Cæsar full marks, when his faulty answers to the grammatical questions have led one to suspect that he simply committed the English to memory, and two or three words with which he has been familiar have given him the clue to the passage. Sometimes, indeed, a candidate fails to recognise the lines selected, and gives an excellent rendering of *another portion* of the book. They give an instance in which a candidate delivered himself of a classically rendered sentence which would have entitled him to special praise, but that it happened to have no reference whatever to the paragraph given to him to translate, of the sense of which he displayed blissful ignorance.

Re-Vaccination of Students.

M. ARTHUR OGIER, only 20 years of age, a student in medicine of the Marseilles School, has just died of small-pox contracted in discharge of his hospital duty. The *Lyon Médical* calls attention to the fact, and considers that M. Gendron has had good reason for insisting that all students at the commencement of their hospital study should be re-vaccinated. It takes credit at the same time for having constantly urged that the student on being entered for hospital attendance should be obliged to produce a certificate *not* of vaccination at some distant period, but of re-vaccination within the current year. "We call," it

says, "once again the attention of the Public Health Department to the question, not thinking it worth while to make any appeal to the Faculty of Medicine, inasmuch as it is, under its administration, quite usual to violate the most elementary rules of hygiene."

Abortion Practice by a Doctor and a Chemist.

At an inquest held at Brighton respecting the circumstances attending the death of a young woman named Hockley, a man named Cole stated that in consequence of the deceased believing that she was *enceinte* by him he had applied to Mr. Darley, chemist and druggist, who had supplied him with several bottles of medicine, for which he had paid 5s. per bottle. Deceased took this medicine, but the object not being attained, Mr. Darley introduced him to Mr. Moon, a surgeon residing in Brighton, who undertook the treatment of the deceased. Deceased subsequently died in the hospital, after a miscarriage. The jury returned a verdict of wilful murder against Moon, and one of being an accessory before the fact against Darley.

St. John's Ambulance Association and the London Hospitals.

A meeting took place at the residence of Dr. Sieveking, 17 Manchester Square, on Saturday, for the purpose of discussing the best means of practical co-operation between the St. John's Ambulance Association, and those London Hospitals which might form Ambulance Committees in connection with it. In addition to Dr. Sieveking, the following gentlemen connected with St. Mary's Hospital were present, viz.: Drs. Shepherd, Wiltshire, Farquharson, Mr. Owen, Mr. Norton, and Mr. Page. Dr. Lionel Beale, of King's College Hospital, was also present; and a letter from Dr. Julius Pollock, of Charing Cross Hospital, showed how warmly the St. John Ambulance movement was approved by the governing body. The Order of St. John was represented at the meeting by Sir E. Lechmere, Bart, M.P., Colonel Gould Weston, Major F. Duncan, R.A., Mr. J. Furley, and Mr. Harford Pearson.

After some discussion as to the best means of carrying out the praiseworthy Hospitaller aims of the Order in time of peace and of war, the following resolutions were arrived at:—

1. That each hospital in London forming an ambulance committee should endeavour to guarantee lecturers to theSt. John's Ambulance classes in the metropolis.

2. That the classes should be examined by the Government military instructors detailed for the Order by the Army Medical Department.

3. That classes of men or women who have obtained certificates may be formed for further instruction under members of the hospital staff; the pupils to receive the further examination from special hospital examiners.

4. That, in the event of war, in which England may be engaged, the hospitals, through their ambulance committees, will aid the Order in finding surgeons, dressers, and nurses for any field hospital or train which it may send out in support of the Army Medical Department, and that the order will employ no one from any hospital without reference to that hospital's ambulance committee.

At a meeting held on the 7th inst. it had been already decided that the medical committee should be composed of the medical members of the St. John's Central Committee, with the addition of the chairman and the secretary of each hospital ambulance committee.

The movement is making rapid strides both in London and the provinces. A new class will be opened in Albany Street on the 20th, and the lecturer will be Mr. Owen, of St. Mary's Hospital. The course extends over five weeks —one lecture a week, of one and a-half hour's duration— followed by an examination.

The Title of "Dr."

Mr. E. L. Hussey, of Oxford, has been at the trouble to print and circulate a letter addressed by him to Dr. Wyllie, Secretary of the Edinburgh College of Physicians, on this subject. The letter, it would appear, is intended not for the person to whom it is addressed, but for Dr. Cumming, who was rash enough to assert that the title "Dr." applied to a licentiate of the College was a "false title."

Mr. Hussey's communication is a curiosity of inconclusiveness, and it will not, we imagine, serve even its doubtful purpose of encouraging physician licentiates to deceive themselves into the idea that they have a right to call themselves "Dr." That these gentlemen are not likely to receive much encouragement from Mr. Hussey's arguments may be judged from the following extract from his letter:—

"Dr. Cumming, if he wishes to make good what he has written, should point out . . . why it is more false for a physician to style himself 'Dr.' than for a surgeon, apothecary, or other professional man to call himself 'Mr.,' without holding the degree of M.A. from a University. There is surely less falsehood in it than in styling himself or any of his friends 'Esq,' or in allowing himself to be so styled by others, without being in possession of an office of honour under the Crown, to which only such a title belongs of right."

It is new light to us and, no doubt, also to Dr. Cumming that a University M.A. is, or ever was, the title of a man to call himself "Mr.," or that an office under the Crown is implied in the remotest degree of the use of the title "Esq."

It is, no doubt, true that the public is wont to call all medical men "Dr.," but it is a different thing for the medical man to dub himself by that title, or to use the letters "M.D.," for that implies an assumption by himself of a name by which he knows he has no right to be called. Mr. Hussey thinks that no more falsehood was seen in the use of such titles than in the courtesy by which the younger sons of a duke or a marquis were called lords, or the judges of the courts were honoured with a similar designation, without being in possession of a peerage.

There is no parallel whatever between the cases which Mr. Hussey compares. When a man calls himself "Dr." he does so because he well knows that the public will give him credit for a University education and an M.D. degree, and, doing so for this reason, he must know that he is obtaining credit from the public on a false pretence.

A New Illuminator.

After the delivery of the annual oration last week at the Medical Society of London, by Dr. Alfred Carpenter,

Dr. Edmunds introduced a new parabolic illuminator, which is a decided improvement upon those already well known to microscopists, and by its aid a large pencil of unrefracted light is condensed upon a microscopic object at almost any angle up to nearly 90 degrees, and at all azimuths. The positive image of the object is seen upon a dark background, even with immersion objectives of the largest angle of aperture, so that a new view of histological significance is obtained of such objects as blood corpuscles, saliva, bacteria, &c., whilst test objects, as diatoms, are more readily resolved than by any other means. The lines of *Amphipleura pellucida*, numbering 200,000 to the inch, are seen as a number of closely set black and green bands. The illuminator is a solid plano-paraboloid lens, upon the plane surface of which the object-slide rests. It is made optically continuous with the substance of the paraboloid by means of a drop of anhydrous glycerine. Parallel rays of light must be thrown upon the base of the paraboloid, which acts on the principle of total internal reflection.

A Specific for Gout, Rheumatism, &c.

THE last few numbers of this journal have contained, as we vainly imagined, a complete list of the superstitious remedies in vogue amongst the labouring classes. Another, however, has cropped up during the last few days, with undoubted proofs of cure, according to its narrators. A woman living in the neighbourhood of Prague is reported to have suffered so severely from gout in the arm that she could obtain no rest or sleep, and the limb in which the disease had settled was rendered entirely useless. Her husband having heard of a countryman who had been completely cured of rheumatism after being accidentally stung by a bee, persuaded the poor woman to try this disagreeable remedy, which, as he pointed out, could hardly prove so painful as the disease. She consented, and allowed three bees to be placed on her arm, and to sting it in several places. Surprising results ensued ; the patient soon afterwards fell into a long and deep sleep, the first real sleep she had enjoyed for six months, after which the acute pain disappeared, and when the swelling produced by the stings subsided the arm recovered the power of motion, and the gout has not since reappeared. Should further experiments establish the efficiency of this mode of treating one of the most troublesome of human ailments, there will be plenty of work in store for the already "busy bee," and, says the *Observer*, "the time-honoured monopoly of modern doctors will have been rudely abolished." Exactly so !

THE mortality last week in the four principal cities of the United Kingdom was—23 in London, 28 in Glasgow, 29 in Edinburgh, and 32 in Dublin, per 1,000 of the population. The excessive death-rate in Plymouth is on the decline. Last week, Dublin, Plymouth, and Edinburgh showed the highest bills of mortality, all the other large towns being under the average.

THE rates of mortality, according to the last weekly return, of the principal foreign cities gave the following results :—St. Petersburgh, the most unhealthy as usual, 61 per 1,000 of the population, Calcutta 49, Madras 47, Buda-Pesth 47, Alexandria 44, Bombay 44, Turin 38, Munich 38, Breslau 38, Venice 33, Rotterdam 33, Vienna 32, Hamburg, 30, Berlin 29, and Paris 25.

WE understand that his Grace the Duke of Richmond and Gordon will receive a deputation from the Medical Defence Association on the subject of the Reform of the Medical Acts, on Monday next, at three o'clock. Members of the profession wishing to accompany the deputation are requested to communicate with "The Hon. Sec., Mr. George Brown, M.R.C.S., 12 Colebrook Row, Islington, N."

THE death of Professor Lamy, of Lille, is announced. As the discoverer of the metal thallium his name came first into notoriety, his claims to a lasting reputation being subsequently confirmed by many original researches in physics and chemistry.

THERE were 60 deaths from small-pox in London, and 17 in Dublin last week. Of the fatal cases in London, 34 were certified as unvaccinated, 10 vaccinated, the remaining being uncertified in this respect.

Medico-Parliamentary

THE SUPPLY OF VACCINE LYMPH.

IN the House of Commons, on Thursday last, Mr. WHITWELL referred to the fact that about £1,000 was voted annually for the purchase of lymph, and inquired whether the greatest possible care was taken to procure matter from the best available sources, or whether the Government had any difficulty in obtaining a perfectly satisfactory supply.

Mr. SCLATER-BOOTH, in reply, stated the whole of the public vaccinators came to the Local Government Board for the matter they required. The lymph so provided was used, not for the re-vaccination of adults, but for the gratuitous vaccination of infants. Before it left the Local Government Office the whole of the lymph was subject to the most minute microscopical examination, and wherever the slightest impurity was discovered the matter was at once rejected. The supply did not come from abroad.

RIVERS POLLUTION PREVENTION ACT.

At the same sitting, Mr. SCLATER-BOOTH, in answer to a question by Mr. Tennant as to what steps had been taken by her Majesty's Government to put in force the provisions of the Rivers Pollution Prevention Act of 1876, said that it was the duty of local boards, and not the Local Government Board, to put the provisions of the Act into operation. A circular had been issued by the Local Government Board informing the local authorities what were their powers and duties under the Act, and immediate effect was given to it in various places such as Salisbury, Canterbury, the Isle of Wight, and other places.

Novelties.

SEABURY AND JOHNSON'S PLASTERS.

AMONG more recent and valuable pharmaceutical improvements, we would draw the attention of the reader to an elegant and convenient lot of plasters prepared by Seabury and Johnson. We have recently tried some of them, and find them to be, severally, very neat, clean, and efficacious preparations. India-rubber has been used as a base in the preparation of these plasters, by which means the medicinal substances used are protected, it is said, from atmospheric influences and preserved from

decomposition. We have not had them in our possession sufficiently long to testify to this fact, but with regard to their therapeutical efficacy, and the style in which they are got up, we can speak from experience. None of them are too strong or irritating; on the contrary, the capsicum plaster and the warming plaster appeared, in the cases in which they were applied, rather too mild. Another advantage is, that they adhere to the skin without heat or moisture, and that they are quite pliable in any temperature. Among the other plasters which have given us great satisfaction, we may mention those in which belladonna and the Spanish fly are, respectively, the chief ingredients.

A PATENT POTASH SOAP.

It often happens, that when a patent article of any kind is brought out its merits are much exaggerated in the prospectus by which the patentee introduces it to the notice of the public. We cannot say that such has been the case with Mackey and Sellers' soap. We have had its qualities tested by persons competent to give an opinion in such matters; and we do not hesitate to state that, in every respect, it answers the description given of it by its makers. It does not contain anything injurious to the materials submitted to its influence. It cleanses and whitens linen better, and with less cost and labour, than any other soap. It can be used either in hot or cold water, and in any description of washing machine. As the dirt is speedily dissolved and discharged without much rubbing being required, its use is not so destructive to clothes as other soaps are. We have even found it a very good soap for shaving, owing partly to the capital lather it forms, and the potash it contains.

Literature.

ON HARE-LIP AND CLEFT PALATE. (a)

The subject-matter of this work has appeared in the St. Thomas's Hospital Reports for 1875-76. Mr. Mason states that in submitting his own experience he has endeavoured to do justice to the labours of others, and a perusal of this volume will show that he has carried out the endeavour fully, and has given to the profession a monograph which will be found to be a valuable aid by those who are called upon to deal practically with cases of congenital hare-lip and cleft palate.

The fissure in hare-lip is most common on the left side of the upper lip, but cases are recorded of fissure in the middle line, and also of the lower lip, but these last are rare. The intermaxillary bone contains the two central incisor teeth in various states of development. Cases are quoted to show that often this deformity is hereditary, and Sir W. Fergusson used to point out partial defects in the lip or jaw of one or both parents. These deformities are sometimes referred to maternal impressions. In discussing the important question as to the period of life when the operation should be performed, the author recommends the second or third month as the most favourable time. Sir W. Fergusson preferred the end of the first month, and assuredly before teething; other surgeons wait until teething is over; others, again, operate immediately or soon after birth. Mr. Mason points out the important fact that some infants get thin and half starved and quite unfit to undergo an operation. Mr. Holmes and Mr. Henry Smith also concur in this opinion, and the latter thinks the child sucks better after the operation, and that if there is a cleft palate its edges become approximated. It has been said that convulsions are apt to follow early operations, but Sir W. Fergusson, in his extensive experience, never met with a case.

The best method of operating is fully described, and the importance of dissecting the soft parts from the superior maxilla and removing enough of the tissue forming the margin of the fissured lip shown—the edges of the cleft are to be brought together either by hare-lip pins and twisted suture or the interrupted suture; the former are very valuable when support is required for the parts, but are to be removed before ulceration is set up—viz, between the second and third day. Mr. Mason gives good advice when he recommends, in cases of partial failure of the operation, the surgeon to persevere in keeping the parts together with strapping, as union often takes place satisfactorily. The intermaxillary bone in double hare-lip is to be removed or bent back, and the soft parts used as a septum for the nose, or, if large enough, to be let into the fissure and kept in place by passing the upper pin through it. In some cases the intermaxillary bone may be removed a day or two before the operation on the fissure, if thought advisable, and a small vessel in the bone may require the application of the actual cautery, which should be at hand. When fed, the child is to be placed in an upright position when cleft palate is present. Different kinds of incisions, more or less complicated, are well explained and illustrated by diagrams.

Various compresses for restraining hæmorrhage are figured, but these are unnecessary when a good assistant is present. Hainsby's truss, which will be found very useful both before and after the operation, is well drawn.

The chief object of the article on Cleft Palate is to put forth the different operative procedures required to close the gap. Many infants die very early of starvation, as they are unable to suck, and food administered by a spoon returns through the nose, and under these circumstances it is recommended to use a teat attached to a feeding-bottle, over which is a shield of soft metal, which can be moulded to the infant's mouth, or the shield may be made of india-rubber, as in Mr. Oakley Cole's instrument. Mother's milk is the best kind of food, but in some instances Messrs. Savory and Moore's food for infants is found to be valuable. Operations for the closure of cleft palate are of comparatively recent date, and used to be deferred until the patient reached the age of fifteen years, but since the introduction of anæsthetics have been performed in children aged five days and upwards. Mr. Mason thinks five or six a suitable age for the operation, as before that age the palate tissues are very thin, and break away readily with the slightest touch of the finger-nail.

Staphyloraphy is the term applied to the operation for the closure of the soft palate. The patient's general health must be well looked to prior to the operation, and enlarged tonsils had better be removed; and it is as well to instruct the patient to tickle the throat every now and then so as to render it less sensitive when touched. The patient had better be purged a day or two before, rather than on the day of the operation. Mr. Thomas Smith did good service in this branch of surgery by bringing forward cases to show the advantage of employing anæsthetics, in a paper read before the Medico-Chirurgical Society, January, 1868, and by inventing an excellent gag, which is known by his name. The gag we prefer is one invented by Mr. Mason, and modified by Sir W. Fergusson, which acts in one side of the jaw, and is very convenient and simple. The steps of the operation are described seriatim, and many useful hints given. With regard to the division of the palatine muscles, as recommended by Mr. George Pollock and the late Sir William Fergusson, Mr. Mason prefers to take the tension off the stitches by a vertical incision through the soft palate on each side of the cleft, as recommended by Dieffenbach. However, if division of the muscles be thought desirable, it is as well to leave it to the last, as the bleeding is free. Sir William Fergusson removed the stitches on the third or fourth day, and with this practice we agree, but Mr. Mason is inclined to leave them to cut their way out, unless they appear to cause irritation. This last is an important reservation. Mr. Mason follows Sir William's example in recommending silk sutures to be used. The patient is to be kept in bed, and to have suitable nourishment.

Uraniscoplasty, or closure of the hole in the hard palate by scraping off the soft tissues from the bone and uniting them in the middle line, is the operation devised by Langenbeck, who contends that the periosteum forms bone, which fills the gap. Surgeons seem to be equally divided as to the advisability of closing both hard and soft palate by one operation. The operation for closure of the cleft by osteoplasty was prominently brought before the profession by Sir William Fergusson in April, 1874, but the operation by this distinguished surgeon seems to have been similar to one devised by Dieffenbach many years previously. Some spiculæ of bone are apt to exfoliate after this operation, to remedy which Mr. Mason proposes to perforate the palate in several places with a bradawl prior to

(a) "On Hare-lip and Cleft Palate." By Francis Mason, F.R.C.S., Surgeon to, and Lecturer on Anatomy at, St. Thomas's Hospital. London: J. & A. Churchill. 1877.

pushing through the chisel. It answers very well to stuff the lateral incisions as soon as made with lint, to stop the bleeding; if done without chloroform, osteoplasty will be found to be less painful than uraniscoplasty. Care must be taken that the edges of the opening be pared, and holes made with the bradawl close to the cleft for the passage of the sutures before the palate bone is divided, but in some instances the sutures are passed through the aperture made by the chisel. If the vomer be attached to one side of the cleft it is better to operate subperiostially on that side, perforating the bone with the chisel on the other. In some instances where the cleft has been approximated but not quite closed by a previous operation, it is possible to bring the parts together by merely stuffing the side incisions with lint, and so dispensing with sutures. After the operation the voice is, as a rule, much improved, and may be still more so, Mr. Mason says, by dividing the soft palate on each side, as described in the *Lancet*, vol. ii., 1869.

With regard to acquired or accidental apertures in the palate, most surgeons are agreed that they do not admit of operations, and had better be treated by apparatus devised by Mr. A. Norton, Mr. Oakley Coles, and others.

LITERARY NOTES AND GOSSIP.

Amongst the names already submitted to the Council of the Royal Society for the much coveted distinction of F.R.S., are Dr. Hughlings Jackson and Mr. Schäfer for their scientific and literary labours. Whilst we sincerely trust that these gentlemen will be elected, there are others whose labours are of longer duration, and of a much more extensive character than the latter of these two candidates. There is Mr. Peter Squire, who has now reached to nearly four-score years without any public mark, for his experimental researches in chemistry and pharmacy, and for his literary works which are spread over the civilised world. Then we have Professor Fleming, of the Army Veterinary Department, who, it is rumoured, will be the next president of the Royal College. Certainly, there is no living writer who has done more than he towards the elucidation of obscure points in pathology, or who has written so large a number of really scientific works. When we mention that in less than ten years he has published five works of from 600 to 1,400 pages each, besides various smaller works and contributions to journals and societies, the enormous amount of work to which we refer will be readily understood. There are others whose names we should rejoice to see decorated with the F.R.S, but refrain spoiling the list by prolixity.

Artists do not prevail very extensively in the ranks of the medical profession; their every-day labours can scarcely be said to favour the production of pictures. Yet we have a few examples of brilliant surgeons who are also real artists, such as Sir Henry Thompson, Mr. Prescott Hewett (we had almost written Sir Prescott Hewett, as gossip has it that he is to be the next medical baronet, a consummation we devoutly desire), and others. The Grosvenor Gallery collection is enriched this year by a beautiful water-colour of Mr. Hewett's, "Corfe Castle," at which our readers will do well to stop for a few moments, and compare the delicacy of touch therein shown by the hand which in an operating theatre is guided and controlled by such an iron nerve.

Gossip is busy about a Testimonial Fund to Professor Erasmus Wilson, F.R.S., which was started in 1873, but by some unaccountable means came to a standstill. Mr. Wilson's munificence in bringing over Cleopatra's Needle at his own expense has revived the slumbering senses of those who think—rightly in our opinion—that his literary labours, together with his liberality in endowing a chair of dermatology at the College of Surgeons and other acts, entitle him to some public recognition. As there was a considerable sum originally subscribed for the purpose, and as far as we can hear, nothing has been done with it, we hope that the idea will be taken up again, and carried through with a spirit worthy the recipient.

Our contemporary, *Nature*, has been enlarged this month, and the price per number increased to sixpence.

The Copyright Commissioners held their final meeting on Saturday last, in order to settle the remaining points relating to international concessions. Medical as well as other authors will be glad to hear that an equitable law which shall protect their works from piracy, especially in America, has been formulated, still more that it has been accepted on the other side.

A graceful compliment was, a few days since, paid to the author of "Outlines of Physiology," &c. (Dr. Allen Thomson) on his retirement into private life, by practitioners in the West of Scotland. The presentation consisted of two portraits, one to the University of Glasgow, of which he has been an honoured representative and professor for the best part of the last half century, the other to Mrs. Thomson.

The following works in Medical Science have been issued during the past week:—"On the Treatment of Rupture of the Female Perineum," by Dr. Bantock (Churchill's). "On the Nature and Treatment of Rabies or Hydrophobia," (Baillière, Tindall, and Cox). "Medical Women," by Dr. C. West (Churchill's). "Tinnitus Aurium," by Mr. Douglas Hemming (Baillière, Tindall, and Cox). "Handbook of Uterine Therapeutics," by Dr. Tilt (Churchill's). "The Pathology of Pulmonary Consumption," by Dr. Hy. Green (Renshaw). "Insanity and its Prevention," by Dr. Hack Tuke (Churchill's). "Henfrey's Elementary Botany," by Dr. Masters (Van Voorst). "Aids to Chemistry," Part II., by Dr. Semple (Baillière, Tindall, and Cox).

Correspondence.

MEDICAL REFORM AND THE PROFESSION.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—We want medical reform; but we want more than the passing of a con-joint scheme or penal clauses. By all means let us get them if we can, but such extra powers, *per se*, will neither elevate the profession or purify the foul spots in our system. We want other reforms—the discountenancing of unprofessional practices, the remodelling of our system of charges, of our bills and book-keeping, of our dunning and collecting, the abolition of clubs and club doctors with their wretched mode of payment, the sweeping away of unqualified assistants, and other such ways and means of keeping together a practice and of getting money from any source, or in any manner.

Proportionate to our numbers we are the poorest profession, but we have contributed to this, by our own conduct. Medical competition, I am sorry to say, is conducted, not only on bad business principles, but in too many cases, by the violation of the laws of honour and rectitude.

"The struggle for existence," no doubt, becomes keener, though that should not justify unworthy practices.

This internal reform must be begun at our large schools of medicine, by our teachers, who should impress that medicine is not a trade, and that all students mistake their vocation who enter it purely to make money, no matter at what sacrifice, and that it would be far better for them, to become tallow-chandlers, grocers, or butchers, when they would be in more congenial spheres of usefulness.

Yours truly, True Reform.

Birmingham, May 4, 1878.

MEDICAL REFORM.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—The high tone your journal has always taken in reference to every question affecting the vital interests of the profession, has deservedly gained for the Medical Press and Circular the respect and support of all who have the honour of their profession at heart. I have followed your remarks on medical reform with a considerable degree of interest, and I thoroughly agree with your views, both on the general reform of the medical acts, and on the internal reform you have so often insisted on.

Amongst the latter, I may reckon your condemnation of the employment of unqualified assistants, and however other journals may try to bolster up this glaring violation of the law, there can be no doubt your statements are not only truthful, but even not sufficiently insisted on, or painted in as strong and powerful colours as you might have used.

In Ireland unqualified assistants are not tolerated, because the Irish public are too intelligent, and I have no doubt when the English public are better informed, as to the way

they have been imposed on, they will also demand the services of the qualified practitioner they sent for.

It is purely a matter of education.

In Ireland we look upon medicine as a profession, and we occupy a higher social position than our English brethren, even though we do not possess so much money. There are many other points in the Irish system which might advantageously be brought into use in the English system—as cash payment in place of book-keeping and bills, prescriptions in place of dispensing, &c., &c. It is only by fearlessly exposing abuses, they can be remedied, and I trust that the PRESS will continue the laudable strictures which you evidently make, not only for the benefit of the profession, but of the public.

Yours faithfully,

Dublin, May 6th. F.R.C.S.I.

UNQUALIFIED ASSISTANTS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—The *British Medical Journal* characterises your statement in reference to the employment of unqualified assistants, "as being overdrawn" (May 4th, 1878).

It could easily be proved to be true. The Medical Defence Association, I believe, has branches throughout the provinces, and probably secretaries in the large centres of population.

This society condemns the system of foisting ignorant pretenders to medical skill on the public,—and this consistency is very commendable. I would suggest, that the committee should instruct their local secretaries to furnish a list of the names of the practitioners who employ unqualified assistants in each town, or district, and especially report as to the number of Poor-law medical officers who do their work by deputy.

I believe such a return would not only be instructive, but would be even *appalling*, and the remarks in your article would then be found to be very feeble, in comparison with the extent and gravity of the evil. The publication in local journals, of the names of the medical men *not employing* unqualified assistants, would educate the public, and strike the deathblow of a system, which has been of the greatest detriment to the profession. I shall glady furnish a list, or assist in any way in my power.

Yours truly,

Liverpool, May 7th, 1878. JUSTITIA.

Medical News.

Royal College of Physicians of London.—At a meeting of the Council on May 9th, the following gentlemen were admitted Fellows of the College :—

John Sykes, M.D. Edin., Doncaster.
Thomas Guy, M.D., Heidelberg, Shaftesbury Road, W.
John Louis Wm. Thudichum, M.D. Giess., 11 Pembroke Gardens, W.
Arthur Ernest Sansom, M.D. Lond., 30 Devonshire Street, W.
William Orange, M.D. Heidelberg, Broadmoor, Berks.
Alfred Wiltshire, M.D. St. And., 57 Wimpole Street, W.
David Lloyd Roberts, M.D. St. And., Manchester.
Charles Henry Ralfe, M.D. Camb., 26 Queen Anne Street, W.
John Mitchell Bruce, M.D. Lond., 60 Queen Anne Street, W.
William Henry Allchin, M.B. Lond., 94 Wimpole Street, W.
John Curnow, M.D. Lond., 3 Warwick Street, Charing Cross, S.W.
Alfred Lewis Galabin, M.D. Camb., 14 St. Thomas Street, S.E.

Royal College of Physicians and Surgeons, Edinburgh.—*Double Qualification.*—The following gentlemen passed their first professional examination during the April and May sittings of the Examiners :—William Thomas Waterson, Netherwitton ; William Stevenson, Stirlingshire ; Ralph Kinder, Manchester ; Marcus Calder, Glasgow ; David Carruthers, Kirkpatrick-Fleming ; Arthur Neol, Brighton ; David Henry Walsh, Bristol ; William Chalmers Cowan, Dundee ; William Bain, Caithness ; William Thomas Thompson, Worcestershire ; Gerald Fitzgerald Thomas, Cork ; Egbert Williams, Llandilo ; Edwin Faulkner, Bangalore, India ; Henry Joseph Clements, County Kerry ; Richard Blair Cullin, Dublin ; Robert William Anderson, Portsmouth ; John M'Nicoll, Liverpool ; William Cochrane Corbett, County Cork ; Arthur Hyde Burtton, Devonshire ; Frederick Herbert Daly, Dublin ; Michael Kelly, Limerick ; George Cuthbert Clarke, Middlesex ; James Murdoch Cameron, Edinburgh ; Perceval Crawford Boyd, Hobart Town ; John Crawhall Nichol, County Durham ; Thomas Henry, County Tyrone ; Charles Wesley Wilson, Ulverstone ; Hugh Davies Jones, Anglesey ; Thomas Morgan Martin, Dublin ; Thomas Matthews, County Down. The following gentlemen passed their final examination, and were admitted L.R.C.P. Edin., and L.R.C.S. Edin :—Albert Elhanan Mallory, Cobourg, Ontario ; Francis Dixon, Derbyshire ; Robert Logan, Dumfries ; James Edwin Eakins, Newburgh, Canada ; Samuel Wellesley Coombs, Oswestry ; Thomas Moynihan, Cork ; Edward M'Callum, Edinburgh ; John Thomas Burgess, Spilsby ; David M'Eniry, Clonmel ; Frederick Aubrey Smith, Manchester ; William George Creswell, Berkshire ; Kenneth Maclean, Stornoway, Lews ; William Nicol Elder, Elginshire ; James Steel, Bushmills ; Charles Jee, Spilsby ; James Griffith Macaskie, Berwick-on-Tweed ; Thomas Neil Cream, Glasgow ; Daniel O'Sullivan, Killarney ; Charles Clark Burman, Whitehaven ; Alfred Stanhope Dawson, Croydon ; John Robertson, Kilmorack, Inverness ; Herbert Saunders, London ; Maurice Alfred Chilton, Wiltshire ; William Duncan Robertson, Montreal ; Robert Stuart Reid, Dunedin, N.Z. ; William Henry Vickerstaff, Macclesfield ; John James Goodlatte Murray, Dublin ; John Chestnutt, Tralee ; Edward Lewis Maunsell, Edinburgh ; Francis George Wright, Southsea ; Andrew Thomas Somerville, New Brunswick ; John Service, Kilwinning ; Robert Nelson Jack, Newton-Stewart ; John Yellowlees Tant, Argyleshire ; John Hay Honeyman, Thurso ; George Annand, Melbourne ; William George Jack, Dunkeld ; John Joseph Gordon, County Sligo ; Llewellyn Thelwall, Wrexham ; James Hartley, Marton ; Froster John Pilgrim, Barbadoes ; Thomas Brayton, Whitehaven ; James Charles Ady, Moulmein, Burmah ; James Steele Boe, Dunblane ; Charles Mason Johnston, Port Louis, Mauritius ; John Joyner Fraser, Tain ; William Alexander Logie, Kirkwall ; Adam Anderson, County Donegal ; Josiah Williams, Cardigan ; George Henry Lamson, New York ; John Wilson Moore, Drogheda ; John O'Brien Curtin, West Newcastle ; Robert Parkin Simpson, Lincolnshire ; James Mithiel Phillips Hosking, Cornwall ; Mackintosh Collie, Elgin.

Royal College of Surgeons in Ireland.—At the last examinations the following candidates obtained the diploma in Surgery of this College :—

Henry Banks, James Barry, Edward Bennett, Henry Arthur Brennan, Walter Peter Carson, Francis Arthur Denning, Maurice O'Connor Drury, Joseph Fitzmaurice, James Garland, F. Gibbons, Robert Gordon, John S. Hawkins, Richard Lawler Hughes, William James Mackie, John Robert M'Munn, Vincent Ffrench Mullen, Archibald John Nicolls, Thomas Joseph O'Donnell, Geo. St. John Oldham, Patrick J. O'Shaugnessy, Walter C. T. Poole, Alexander Philip, Blacker C. Powell, Edmund Rundle, Thomas Wm. Smartt, Thomas Bennett Walley, Robert Warnock, Cecil George Westropp.

Royal College of Surgeons, Edinburgh.—The following gentlemen passed their first professional examination during the April sittings of the Examiners :—William Albert Maurice de Matteville, Berne ; Alexander Henderson, Perthshire ; Isaac Williams, ---- ; John Tubb Thomas, Pontypool ; William Doughty, Shropshire ; and the following gentlemen passed their final examination, and were admitted L.R.C.S. Edinburgh :—Edward Fowler Scongal, Cheltenham ; Raglan Wykeham, Barnes, Aylesford ; Thomas Charles Walker, Linlithgowshire ; Henry Ruby Harley, Cork ; Hanmer Dickson, Tripoli, N. Africa ; Eugene Joseph O'Mullane, Mallow ; Charles Walker Cathcart, Edinburgh ; James Mulligan, Dromore ; David Collie, Edinburgh ; Charles Albert Bestall, Wicklow ; Edward Harwood Bowker, Derbyshire ; Alexander Henderson, Perthshire.

Pharmaceutical Society of Ireland.—At a special meeting of the Council of the above Society held at the College of Physicians on Wednesday, the 8th May, Prof. Tichborne, Ph.D., F.C.S., &c., was unanimously elected President, in place of Sir

Dominic Corrigan, Bart., resigned. Dr. A. Smith, Vice-President, declined to accept the post of President, and requested the Council to allow him to remain as Vice-President of the Society. Mr. Bennett, of Kingstown, and Mr. Brunker, of Dublin, were elected to fill the two vacancies on the Council.

Slow Combustion Stoves.—His Royal Highness the Prince of Wales is said to be somewhat æsthetic in his household tastes; and anxious to set an example in sanitation and domestic economy, made, as his first purchase in the Paris International Exhibition, a slow combustion stove, manufactured by Messrs. Barnard, Bishop, and Barnard, of Norwich, with the principle of which his Royal Highness seemed greatly pleased.

Ventilators.—We are asked by the Registrar of the Sanitary Institute of Great Britain, to mention that, by permission of the Kew Committee of the Royal Society, the various ventilators shown at the Leamington Exhibition last October, have been transferred to Kew, where a further series of experiments will be conducted during the present month. Members of the profession will be supplied with cards of admission, on application to the Sanitary Institute, Spring Gardens, London, S.W.

Samaritan Free Hospital for Women and Children.—Sir Thomas Chambers, Q.C., M.P., Recorder of London, presided over the anniversary dinner in connection with this institution, which took place last week. In the course of his remarks, in proposing the toast of the evening, the chairman spoke of the remarkable success which had attended the dangerous and difficult operations performed at the hospital with a success which a few years ago would have been deemed incredible. During the evening subscriptions amounting to £2,000 were announced.

Australian Wines.—Now that the Prince of Wales has tasted and approved of Australian wines possibly they may become more popular. On Saturday the Prince paid a visit to the Paris exhibition, and tasted various wines produced in the colony. If we remember rightly, it was Mr. Vitzetelly who tasted these Australian wines at the Vienna Exhibition, giving them the highest character, and stating that some of the better and finer qualities had even been mistaken by competent judges for superior Bordeaux wines. With such testimonials, and now with a Royal recommendation, the Australian wines ought to find favour and become more generally known and consumed.

NOTICES TO CORRESPONDENTS.

Mr. W. J. Bowden will lecture "On Acne" at 4 o'clock on Thursday, and Mr. J. Startin "On Parasitic (Vegetable) Diseases" on Monday next at the St. John's Hospital for Skin Diseases. The profession are admitted free.

Neutralising Poison.—It is stated in an American contemporary that any description of poison in any degree of potency can be rendered almost instantly harmless by simply swallowing two gills of sweet oil, this oil neutralising every kind of vegetable, animal and mineral poison. Individuals with very strong constitutions will require double the quantity of oil.

Dr. Robertson.—If you will send us the communication we will decide upon its suitability.

Minor.—Write to the Secretary at the College, who will furnish you with the desired information.

A Bookworm is referred to our "Literary Notes and Gossip" in the last number.

Harveian Society.—To-morrow, at 8.30 p.m., Dr. Hughlings-Jackson will bring forward a case of a "Large Tumour of the Left Cerebral Hemisphere," and Mr. Lister will read a paper on "The Effects of Position upon Local Circulation."

Pharmacist.—The formula given by the "Magazine of Pharmacy and Chemistry" is correct.

Medical Officer of Health.—It is not for us to decide upon the rival merits of carbolic acid, chloralum, Burnett's Fluid, Condy's Fluid, and Sanitas. Each is good in its way, all are good disinfectants, but all would not be equally useful in every case. The purpose should indicate which is preferable.

Royal Medical Benevolent College.—Notice is given of an election of one pensioner and ten foundation scholars on the 27th inst. The ballot-papers must be sent to the office, 37 Soho Square, London, W., properly filled in signed before that date.

Unprofessional Advertising.—A correspondent in Edinburgh has forwarded us the *North British Daily Mail*, with a marked quotation of Dr. Cassells' lecture on "Aural Surgery" at the Royal Infirmary School of Medicine, asking us if it is not derogatory to the dignity of the profession for lecturers to advertise themselves in this way. Our opinion on this subject has been so recently expressed in a similar case in Dublin that we need not repeat it. We can scarcely believe that Dr. Cassells had any knowledge of the circumstance, or that he would have sanctioned the reproduction in a lay paper of remarks made by him to medical students. In any case, professors who value reputation amongst their colleagues should at all times discourage this form of public notoriety.

Dr. Laffan.—Waiting return of proof.

A Poor-law Medical Officer.—Your letter will appear in our next.

Dr. Jas. A. Sewell, Quebec.—Your communication received, and will appear in our next.

The *Students' Journal* is responsible for the following:—"Why is a doctor better taken care of than his patients? Because when he goes to bed somebody is sure to rap him up."

An exchange improves the occasion of a boy in Detroit getting a brass-kettle fixed immovably on his head. He comments: "It is strange they didn't think to carry him to a brass-foundry and have it melted off. Or they might have dissolved it off by laying the boy in soak in a tank of dilute nitric acid. It is curious how thoughtless some people are in moments of emergency."

BOOKS AND PAMPHLETS RECEIVED.

Outlines of Physiology, its Relation to Man. By J. Gray McKendrick, M.D. Glasgow: James Maclehose.

A Handbook of Uterine Therapeutics and of Diseases of Women. By E. J. Tilt, M.D. London: J. & A. Churchill.

Transactions of the American Dermatological Association.

Fifth Annual Report of the Medical Officer of Health for Macclesfield.

Our Debt and Duty to the Soil. By E. D. Girdlestone.

Consumption and Climate. By Dr. de Pietra Santa.

The Use and Abuse of Pessaries. By G. G. Bantock, M.D.

Tinnitus Aurium. By W. Douglas Hemming, M.R.C.S. London: Baillière, Tindall, & Cox.

Medical Women; a Statement and an Argument by Charles West, M.D. London: J. & A. Churchill.

The Twenty-third Annual Report of the Poplar Hospital.

Insanity in Ancient and Modern Life. By D. Hack Tuke, M.D. London: Macmillan & Co.

APPOINTMENTS.

Fox, T. C., M.D., a Physician to the St. George and St. James Dispensary, King Street, Golden Square.

Drummond, D., M.A., M.D., Physician and Joint Lecturer on Clinical Medicine to Newcastle-on-Tyne Infirmary.

Mehan, J., L.R.C.S.Edin., &c., Visiting Physician to the Limerick Union Workhouse.

Nesbitt, R., L.R.C.S.I., &c., Resident Medical Officer and Registrar to the County Infirmary, Monaghan.

Noble, J., M.B., C.M., Parochial Medical Officer for Crathie and Braemar, Aberdeenshire.

Perry, E. V., L.R.C.P.L., M.R.C.S.E., Medical Officer for the No. 1 District of the Aylsham Union, Norfolk.

Rowland, R., F.R.C.S.E., Medical Officer to the Workhouse, Tregaron Union, Cardiganshire.

Army Medical Department.—Surgeon-Major C. W. Poulton, M.D., retires on half-pay with the rank of Deputy Surgeon-General.

Births.

Ashe.—May 8, at the State Asylum, Dundrum, co. Dublin, the wife of Isaac Ashe, M.D., T.C.D., of a daughter.

Grayson.—May 7, at Rayleigh, Essex, the wife of F. Dorrell Grayson, M.R.C.S., of a daughter.

M'Dowell.—May 6, at Ballickmoyler, Queen's Co., the wife of Dr. F. V. M'Dowell, of a son.

Slater.—May 5, at Evesham, the wife of J. S. Slater, M.R.C.S., of a daughter.

Thornhill.—May 8, at St. Martin's, Guernsey, the wife of T. A. Thornhill, M.B., Surgeon-Major Army Medical Staff, of a daughter.

Vines.—May 3, at Ferry House, Littlehampton, the wife of H. J. Kendrick Vines, F.R.C.P.Edin., of a son.

Wood.—May 10, at the Priory, Roehampton, the wife of W. E. Ramsden Wood, M.A., M.B. Cantab, of a daughter.

Marriages.

Ormerod—Milner.—May 9, at St. Stephen's, South Dulwich, J. A. Ormerod, M.B. Oxon, M.R.C.P.Lond., to Mary Ellen, daughter of Edward Milner, of Dulwich Wood.

Thurston—Reid.—May 9, at St. Luke's Church, Paddington, E. Paget Thurston, B.A., M.B., of Claremont Ore, to Anna, daughter of the late Rev. W. Reid, of Kircudbright, N.B.

Deaths.

Allison.—On April 30, at Barrow-in-Furness, Lancashire, Joseph Allison, L.K.Q.C.P.I., aged 59.

Baldwin.—On May 1, at Woodville, co. Waterford, John P. Baldwin, L.K.Q.C.P.I., aged 27.

Bernard.—On May 6, at Clifton, J. Fogo Bernard, M.D., aged 71.

De Landre.—On April 26, at Waterford, Vernon Russell De Landre, L.R.C.P.Ed., aged 33.

Dewar.—On April 26, at Kirkcaldy, James Dewar, M.D.

Dudley.—On April 30, at Over Cheshire, Charles Dudley, L.S.A.L., aged 63.

Geoghegan.—On May 6, at Lucan Crescent, Elizabeth Geoghegan, widow of W. P. Geoghegan, M.D., aged 78.

Humble.—On April 23, at St. Lawrence, Ramsgate, William Humble, M.D., aged 30.

Johnston.—On May 1, at Maguiresbridge, co. Fermanagh, Mary, wife of Dr. R. G. Johnston.

Mantell.—On April 29, at Faringdon, George Houston Mantell, M.R.C.S.E., aged 63.

IRISH POOR-LAW INTELLIGENCE.

THE INQUEST AND MEDICAL WITNESS SYSTEM IN DUBLIN.

We are pleased to be able to state that the efforts of the Irish Medical Association have at last put an end to the illegal and improper system of obtaining medical testimony at inquests in Dublin, to which we have repeatedly called attention in these columns. We shall return to this subject in our next issue.

CORRESPONDENCE.

APPOINTMENT AND REMUNERATION OF SUBSTITUTES FOR DISPENSARY MEDICAL OFFICERS DURING SICKNESS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—The attention of the Council of the Irish Medical Association has been frequently directed to the proceedings of boards of guardians and dispensary committees with reference to the remuneration of practitioners who have acted as substitutes for dispensary medical officers, in case of the incapacity of those officers to discharge their duties in consequence of sickness, and the council has observed that the regulations of the Local Government Board on this subject seem to be very imperfectly understood by guardians and members of committees, and that frequent disputes have arisen in consequence of the omission of the dispensary medical officer to adopt the course indicated by those regulations. With the object, therefore, of preventing contests of opinion on this subject, and putting both the dispensary medical officer and the *locum tenens* in their legitimate position as regards remuneration, the council deems it desirable to recapitulate the Regulations governing the matter, and to point out the course indicated by those Regulations to be pursued by both medical men.

That course is governed by the 22nd article of the Dispensary Regulations, which runs as follows :—"If a medical officer of a dispensary district be temporarily incapacitated, by illness or other cause, from performing his duties, he shall immediately, if practicable, communicate with the chairman or honorary secretary of the committee, and shall recommend to the committee a medical practitioner qualified as hereinbefore provided (in Article 20), to perform his duties during such temporary incapacity. And on the fact of the medical officer's incapacity becoming known, a special meeting of the committee shall be at once called, in accordance with Article 13 of this Order, for the purpose of appointing a temporary substitute for the medical officer ; and the committee shall report the circumstances of the case to the board of guardians, who shall, subject to the approval of the Commissioners, determine the amount of remuneration, if any, to be paid to the temporary substitute. And for the time during which such temporary substitute, appointed by the Committee of Management, shall act as medical officer, he shall perform all the duties of the medical officer, and shall duly enter up the books of the dispensary for such time before any remuneration that may be agreed upon be paid to him."

The council direct attention to the fact that—in the terms of this Regulation—the duty of a dispensary medical officer, in case of his being "temporarily incapacitated by illness or other cause," is strictly confined, firstly, to his "immediately, if practicable, communicating with the chairman or honorary secretary," and "*recommending*" a duly qualified *locum tenens*. He is not authorised to appoint his substitute, and the committee has full discretion to act upon his recommendation, or to disregard it, if they see fit. He has not any authority whatsoever to make arrangements with the *locum tenens* as to his remuneration, nor would any promises made by him be in the least binding either on the committee or the board of guardians. He is simply directed to suggest to the committee the name of a medical man who possesses the qualifications required by the regulations, and in doing so he will, of course, act rightly in recommending a practitioner who can conveniently and effectually discharge the duties for the advantage of the sick poor.

The council does not fail to recognise the existence of circumstances which may make it occasionally desirable for the dispensary medical officer to arrange *ad interim* for the discharge of his duty, until he shall have had time to communicate with the chairman or secretary of the committee, and the council therefore advises that in such exceptional cases adequate temporary provision should be made for attendance on the sick poor, until it may be possible to act upon the strict terms of the Regulations.

On the other hand, the practitioner who acts as *locum tenens* should understand that his doing so is irregular until he has had a definite appointment from the responsible officer of the dispensary committee, and that he has no claim whatever for remuneration except on a definite arrangement on the subject with such officer. He will, no doubt, in circumstances of urgency, act upon the request of the medical officer *ad interim*, until the secretary or chairman of the committee can be communicated with, but he will distinctly understand that by so doing he acquires no claim—moral or legal—upon the medical officer. He should remember also that if he omits to obtain at the hands of the committee, or its responsible officer, a definite appointment and a definite understanding as to payment, he does so at his own risk, inasmuch as it is the regulation that the guardians "shall, subject to the approval of the Local Government Board, determine the amount of remuneration (*if any*) to be paid to the temporary substitute," and it is therefore quite open to the guardians (and

boards have frequently availed themselves of the power) to refuse to pay anything for such services, unless they have previously contracted with the *locum tenens* for a suitable remuneration for his services.

The council also desires to point out that the dispensary medical officer who complies strictly with the terms of the Regulations, as above referred to, is entitled as a matter of right to receive his salary during the continuance of his illness, and it is not within the power of the guardians to refuse payment, or to make any deduction from the amount, either for remuneration of the *locum tenens*, or for any other purpose, unless a special arrangement to that effect shall have been previously made between them and the medical officer for that particular occasion.

It is not within the authority of a board of guardians, by any resolution made at the time or previously, to alter the provisions of the Regulations, or to create a rule having such effect; and in case of their refusal to pay the *locum tenens*, the dispensary medical officer is not bound in honour or in law to make good such payment, unless he has an implied or expressed understanding with the *locum tenens* to that effect.

The council—though considering it necessary to offer to Poor-law medical officers this explanation of the Regulations—have no intention of interfering with the discretion or personal convenience of such officers in this matter. The council seeks simply to remove misapprehensions which have very frequently caused regretable disputes between dispensary medical officers, practitioners acting for them, and the guardians under whom they act.

Yours faithfully,

J. W. Moore, M.D.,
Secretary of Council, I. M. A.

DISPENSARY TICKETS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—Would you inform me (1) am I bound to attend on dispensary tickets issued under the following circumstances :—

In my district several gentlemen—members of the committee—sign a number of blank tickets, and leave them with their stewards and bailiffs to fill in and issue to anyone applying for them.

The wife of one of the members of the committee keeps a small shop, and *signing her husband's name* to them, issues tickets to all applicants—her customers—from far and near.

(2). I would also like to know if I am right in supposing that one of the objects of having so many committee men and wardens scattered through the districts, was that they might issue "visiting tickets" only to those in their immediate neighbourhood, and therefore be able to ascertain if there was actual necessity for them and that the parties applying for them were too ill to attend at the dispensary.

(3). Can a dispensary doctor legally refuse to extract teeth when a ticket is presented to him by a dispensary patient for that purpose?

Yours obediently,

M. B.

[1. The practice of issuing tickets by deputy is distinctly illegal, improper, and contrary to the intention of the law. Article 31, of the Dispensary Regulations (see "Irish Medical Directory," page 250) says :—"The ticket and counterpart are both to be filled up by the person authorised to issue the ticket . . . Care should be taken in the issue of the tickets accordingly, and . . . with all available information as to the nature of the case." Notwithstanding the terms of this—their own—regulation, the Local Government Board, on the matter being brought under its notice, took no steps to remedy the abuse of issuing tickets by deputy, but stated that although such issue was improper and illegal, the medical officer must attend upon such tickets.

2. Wardens were appointed for this reason, but inasmnch as there is no requisite qualification for that office, a warden may be anyone, even a potboy or a shop assistant.

3. Certainly, he *cannot* refuse.—Ed. M. P. & C.]

OBSERVATIONS OF THE COUNCIL OF THE IRISH MEDICAL ASSOCIATION ON "THE MEDICAL ACT, 1858, AMENDMENT BILL."

The following Report of the Committee of Council was unanimously adopted a a Special Meeting of the Council held on Tuesday 7th inst. at the Royal College of Surgeons.

The Council of the Irish Medical Association view with satisfaction any attempt at legislation which may tend to improve medical education and medical examinations, and to remove the present unsatisfactory state of the qualifications which entitle their holders to admission to the *Medical Register*. The Council do not think that the present Bill can be considered as sufficiently fulfilling the above objects, for the following reasons :—

1stly. That the constitution of the General Medical Council is not affected by the Bill: the General Medical Council, as at present constituted, only directly represents the Government and the Corporations, but scarcely at all the great bulk of the medical profession. That while it is owing to the failure of the Corporations to adopt conjoint examinations, and the omission of the General Medical Council to enforce uniformity of education and examination, that the proposed legislation has become necessary, yet the regulation of examinations is to be almost altogether vested in the representatives of the licensing bodies. The Council of the Irish Medical Association consider that the Bill should provide for the direct representation of the great body of the profession in the General Medical Council, each division of the United Kingdom being duly and separately represented.

2ndly. That the Bill does not make efficient provision for uniformity of examination, and still leaves the nineteen portals open for admission to the *Register*. Experience has proved that a majority of the medical authorities are indisposed to unite for the promotion of conjoint examination schemes, and unless some power of *compelling united action* be provided in the Bill, there is no prospect of a single examining body being formed for each division of the United Kingdom.

Lastly, there are some minor defects in the Bill which the Council believe require amendment; they therefore beg to make the following observations upon the Clauses of the Bill :—

DOUBLE QUALIFICATION.

Clause 3. This Clause requires "a double qualification," that is, a diploma in medicine and a diploma in surgery, for admission to the register. This the Council approve, but think that either a diploma in midwifery should also be included in a complete qualification, or that the examination should be such as would secure an adequate knowledge of midwifery.

FOREIGN AND COLONIAL DEGREES.

Clauses 5, 6, and 7 provide for the registration of colonial and foreign qualifications, such registration being granted to British subjects only after ten years' practice abroad, and provided that such qualifications entitle the

holder to practise in the country in which the diploma is issued. This appears to be a valuable and just provision, *provided it be reciprocated by the colonial and foreign governments.*

ERASURES FROM REGISTER.

Clause 11 provides for the erasure from the *Register* of the names of persons guilty of felony or misdemeanour, or of any infamous or disgraceful professional conduct. This clause is approved, but at the end a provision is introduced which exempts from its operation a person who has been guilty of an offence, *trivial* in its nature, or committed under excusable circumstances. The Council think that all such exceptions should be omitted.

EXAMINATION RULES.

Clause 14 makes it incumbent upon the General Medical Council to make rules for the examinations. The Council approve of the sub-clauses, except (2), "which provides that the examination rules shall not require a candidate to adopt, or refrain from adopting, the practice of *any particular theory* of medicine or surgery." It is manifest that this sub-clause would give the candidate power to answer questions according to *his own views*, and obtain credit therefor, quite independently of the opinion of the examiners as to the correctness of the answer. In sub-clause (4, &c.) an exception is made in favour of *women* admitted to examination, that they shall have the *power to object* to pass the "*same examination as men.*" This would give female candidates the power of choosing the manner of examination. The Council, without expressing any opinion as to the advisability of admitting women to the medical profession, are distinctly of opinion that, if admitted, they should comply with the same conditions as are required of men.

CONJOINT EXAMINATIONS.

Clauses 15, 16, 17, and 18 make provision for the formation of Conjoint Examining Boards, and for the regulation of such Boards. They also remove any legal objections which may at present exist as to the formation of such Boards. These clauses are all *permissive*, and the Council are distinctly of opinion that unless such clauses be made *compulsory*, they will prove *inoperative*. It is quite understood that if the Medical Authorities in each division of the United Kingdom had formed Conjoint Examining Schemes, under section 19 of the Medical Act of 1858, little necessity would have existed for any of the proposed legislation.

UNLICENSED PRACTICE.

Clause 22 makes more effectual provision against quacks, but does not prohibit the practice of unqualified persons. The Council think that practice "*for gain*" by *unregistered* persons should be made penal. This clause also deprives private persons of their privilege to prosecute unregistered persons, and makes it *permissive* for the Medical Council, or the Corporations, to prosecute. There does not seem to be any reason why private persons should be deprived of their present right in this matter.

DENTAL PRACTITIONERS.

Clause 23 provides for the examination and registration of Dentists. This clause is very objectionable, and contrary to the principle of the Bill, which requires a qualification in medicine and in surgery to admit to general practice; but this clause would permit a person who is not a surgeon, or not in possession of any existing dental diploma, or *any qualification whatever*, to practise dental surgery, and to be registered as a legally recognised dental practitioner.

MIDWIVES.

Clause 24 provides for the examination and registration of midwives. This is, no doubt, a much required and useful measure; but the sub-clause 5, which provides for the appointment of local examinations and local registers, is most objectionable: it even provides that local bodies, like town councils, may become the controlling authority in such matters. The licensing of midwives should be confined to properly constituted *medical* bodies.

IRISH MEDICAL ASSOCIATION.

QUARTERLY REPORT OF THE PROCEEDINGS OF COUNCIL FOR THE TERM ENDING MARCH 31, 1878.

DURING the past quarter the Committee of Council held fourteen meetings, and your instructions have been carried out.

The Public Health (Ireland) Bill.

This Bill, as at present arranged, stands for committee of the House of Commons, and it is thought likely that it will very soon be taken up. During the quarter just ended the Committee of Council communicated with Mr. Meldon, M.P., who has already given notice of several amendments to be proposed by him when the Bill comes under consideration, and these amendments include all the suggestions put forward by this Association; notice of many other unobjectionable amendments has also been given.

The British Medical Association having kindly offered to assist in promoting the amendments suggested by this Association, the offer was accepted with thanks, and copies of the various papers on the subject were duly forwarded to the secretary.

The Committee of Council having observed that a deputation from the Public Health Committee of the Dublin Corporation had waited upon the Chief Secretary with a view to obtaining amendments in the Public Health Bill, they directed that application be made to the Chairman of the Public Health Committee for a copy of the amendments suggested, and upon receipt of same they met specially to consider them, when it was found that almost all the amendments suggested were in accord with the views of this Association. The Committee of Council therefore directed that the Chief Secretary be informed, seriatim, which of the proposed amendments were approved or disapproved by this Association, and that similar information be forwarded to the Public Health Committee. These instructions having been carried out, the Chief Secretary formally acknowledged the receipt of the letter sent to him, and the Public Health Committee expressed gratification that so many of the amendments suggested by them coincided with the views of this Association.

The Proposed Vaccination Bills.

In reply to the letter referred to in last quarterly report, the Committee of Council addressed a letter to Sir Michael E. Hicks Beach, Bart., late Chief Secretary for Ireland, stating that, as the Council were desirous of assisting in the perfection of the vaccination laws, they hoped he would have the goodness to point out which of the amendments proposed in these Bills appeared to him to be objectionable. The Committee of Council also expressed their opinion, that experience concerning the arrangements recently made by the Local Government Board for collecting and gratuitously distributing vaccine lymph, could in no way assist or interfere with the desired legislation. The receipt of the letter was formally acknowledged, but it is probably owing to the changes which have since taken place that no further letter has been received from the Chief Secretary on the subject.

The Registration of Births and Deaths Bill.

Letters from the Right Hon. the Earl of Donoughmore and also from the Attorney-General for Ireland were received, stating that as soon as the new Chief Secretary for Ireland is appointed they would ask him to put this Bill in train for inquiry.

The dispensary medical officer, whose case was referred to in the last two quarterly reports, who, as registrar of marriages, had been summoned to give evidence on behalf of the Crown relative to a forged certificate, acting upon the advice of the Committee of Council, applied to the Under Secretary at Dublin Castle for payment of his fee and expenses, and in reply received an order for payment of a fee of one guinea, and ten shillings for car-hire (the amount of expenses claimed); but as it appeared to the

Committee of Council that their correspondent was, by the recent orders of the late Attorney-General for Ireland (in consequence of his not being a resident in the town in which the petty sessions were held), entitled to a fee of two guineas, they advised him to apply for that amount, but as yet have not heard the result of his application.

Coroners' Medical Witnesses.

With reference to the complaint, alluded to in the report for the quarter ended 25th September last, concerning the conduct of one of the coroners for the county of Dublin in bringing with him, and employing as medical witness at an inquest, a gentleman who resided over twenty miles from the place where the death happened, to the detriment of the medical practitioner "in actual practice at or near the place," the Committee of Council have instructed Mr. Lloyd, solicitor to the Association, to submit the matter for an opinion of counsel, and to request advice not only concerning the point at issue in this case, but also generally with regard to—

1. The duties of the police under the 22nd section of the Coroners' Act (9 & 10 Vic., cap. 37), stating whether they are thereby required to inform the coroner of the name and address of any legally qualified medical practitioner who was in attendance upon the deceased at or about the time of death?

2. Is the coroner, upon receiving such information, bound by the same section forthwith to issue a summons to such medical practitioner to attend and give evidence at such inquest?

3. Is it legal for a coroner, under the 33rd section, to ignore the existence of a duly qualified medical practitioner "in actual practice at or near the place where the death happened," who is ready and willing to give evidence at the inquest, and substitute for him as medical witness at an inquest a medical practitioner who is not "in actual practice at or near the place where such death happened?"

4. What steps should be taken concerning the present complaint, as well as to prevent a repetition of such conduct?

As stated in last quarterly report, no reply having been received from the commissioner of the Dublin Metropolitan Police to the letter of the 12th December, 1877, addressed to him by order of the Committee of Council, requesting that instructions might be issued to the police when giving notice to the coroner concerning a sudden or violent death, that they shall in future also state the name and address of any legally qualified medical practitioner who was in attendance upon the deceased at or about the time of death; the following correspondence ensued, viz.:—

Irish Medical Association,
Royal College of Surgeons, Dublin,
12th December, 1877.

To Captain Talbot,
Chief Commissioner,
Dublin Metropolitan Police.

SIR,—I am directed by the Council of the Irish Medical Association to forward to you the enclosed copy of the judgment delivered by the Court of Queen's Bench on the 19th November, 1877, in the case of "The Queen at the prosecution of Jacob v. Finlay," relative to medical witnesses at coroners' inquests; and to ask your attention to the 9th & 10th Vic., cap. 37, s. 33, which directs the coroner to summon as medical witness at each inquest a "legally qualified medical practitioner, being at the time in actual practice at or near the place where such death happened," because this provision of the law is not generally complied with by the coroners, who it appears are not informed by the police, when giving notice of deaths for the purpose of inquests being held, of the name and address of any such practitioner, and in consequence they (the coroners) frequently call to their assistance some practitioner not qualified by being in *actual practice at or near the place of death*, as directed by the Act above referred to. The Council are of opinion, that the intention of the *Legislature* evidently was, that a medical practitioner who was likely to be aware of the facts connected with the occurrence of each sudden or violent death should be heard in evidence at the inquest, such practitioner being calculated to supply the most satisfactory evidence as to the case of death; and have therefore directed me to bring the matter under your notice in the hope that you may see fit to issue instructions to the police that they shall, when giving the usual notice to the coroners, inform them of the name and address of the legally qualified medical practitioner (if any) who was in attendance upon the deceased shortly before, at, or immediately after the occurrence of death—or of a legally qualified medical practitioner in actual practice at or near the place of death, in order that such medical practitioner may be summoned to give evidence at the inquest, in accordance with the provision of the law, whereby the Council believe the public interests would be served.

I am, Sir,
Your obedient servant,
JOHN H. CHAPMAN, Hon. Sec.

Irish Medical Association,
Royal College of Surgeons,
7th February, 1878.

To the Chief Commissioner of
Dublin Metropolitan Police.

SIR,—By direction of the Council of the Irish Medical Association I addressed a letter to you on the 12th Dec. last, expressing the hope of the Council that you may see fit to issue instructions to the police that they shall, in future, when giving notice to the coroner concerning a sudden or violent death, at the same time inform him of the name and address of a medical practitianer (with a view to his being summoned as medical witness at the inquest) qualified as directed by the 9 & 10 Vic., cap. 37, sec. 33, which is the law in force at present regulating all matters connected with coroners' inquests in Ireland; and I am now directed to state that the suggestion of the Council has already been adopted by the Inspector-General of the Royal Irish Constabulary; and also that the Council hope you will have the goodness to favour them with a reply at your earliest convenience, which, they trust, may be an approval of their suggestion.

I am, Sir,
Your obedient servant,
JOHN H. CHAPMAN, Hon. Sec.

(To be continued.)

LIST OF ENTRIES IN THE REGISTER OF THE BRANCH MEDICAL COUNCIL (IRELAND) FOR THE MONTH OF APRIL, 1878.

APRIL 2nd.—Fitzgerald, Cornelius Gerald, Clonbealy House, Newport, co Tipperary, Lic. R. Coll. Surg. Irel. 1877.

2nd.—Collis, Robert W., Lancaster Infirmary, Lancaster, Lic. R. Coll. Surg. Irel. 1877, Lic. 1878 and Lic. Mid. 1878 K. Q. Coll. Phys. Irel.

2nd.—Morris, Thos. Wm., Tralee, co. Kerry, Lic. Apoth. Hall Dub. 1878.

3rd.—Hassard, Richard John, Bellefield, Kilpedder, co. Wicklow, Lic. R. Coll. Surg. Irel. 1877, Lic. K. Q. Coll. Phys. Irel. 1878.

4th—Cooke, Wm. Davis, Clonmel, co. Tipperary, Lic. Apoth. Hall Dub. 1869.

9th.—Mackay, Wm. Brittain, 2 Upper Hatch Street, Dublin, Lic. R. Coll. Surg. Irel. 1877, Lic. 1878 and Lic. Mid. 1878 K. Q. Coll. Phys. Irel.

15th.—Allen, Edmund Henry, Saunderfoot, Pembrokeshire, Lic R. Coll. Surg. Irel. 1876, Lic. 1878 and Lic. Mid. 1878 K. Q. Coll. Phys. Irel.

18th.—O'Neill, Edward Daniel, Melrose Villa, Rathgar, co. Dublin, Lic. R. Coll. Surg. Irel. 1877, Lic. K. Q. Coll. Phys. Irel. 1878.

18th.—Mallins, Clement, Grosvenor House, Rathgar, co. Dublin, M.B. 1877 and B.Ch. 1878 Univ. Dub.

18th.—Starkey, William, 54 Lower Sackville Street, Dublin, M.D. 1869, and M.Ch. 1870, Q. Univ. Irel., Lic. Apoth. Hall Dub. 1869.

ALCOHOLIC DRINKS: AS MEDICINES, AND AS POISONS. (a)

By ALFRED CARPENTER, M.D. Lond., M.B., J.P.,
President of the Croydon Microscopical Society, Lecturer on State Medicine, St. Thomas's Hospital, &c.

(*Continued from page* 401.)

A stimulant in moderate doses promotes the secretion of gastric juice; it brings flush of blood to the capillaries which surround the g tric follicles, produces congestion. This is relieved by a free flow of gastric fluid, and the rapidity of digestion is promoted. But the action is followed by a re-action, and the next day there is a deficiency of gastric juice, and as a consequence a want of appetite. The deficiency may be remedied by another dose of the irritant. The dyspeptic symptoms are relieved, for the time being, by "pick-me-up," and so each daily exhibition leads to increased dyspeptic disturbance, until the follicles are so altered that the whip no longer acts, and the general health fails. If an excess of stimulant is taken at any one time, it acts immediately on the pepsin in the gastric juice, as well as the lining membrane on the vessels, and destroys the power of digesting and re-arranging the materials which are contained in the food.

There is no difficulty in accounting for the anorexia of the drunkard, or for the temporary flash and power which another dose of his liquor provides for him.

The rapidity of the current of blood being delayed in the capillaries of the stomach their tension is interfered with, they dilate, and a larger quantity of blood is present than is right; as a sequence, local warmth is promoted, and, in vulgar parlance, "coppers are hot." But it has been fully proved by accurate observers, that the quantity of heat in the body is not materially added to by alcohol, but that, on the contrary, there is a reduction from the general amount in consequence of the loss which arises from increased radiation from the surface of the body. The temperature of the "dead drunk" man is lower than that which usually marks the natural heat of the body. This rule does not obtain at all times, as there are exceptional conditions which occasionally modify it. A dead drunk man often has some disease going on in his body which raises the temperature to above 98·5; but if there be no active disease, and if the temperature of the body of an insensible person is found below the natural standard without any evidence of collapse from any other cause, it may be safely assumed that he is drunk rather than that he is suffering from active cerebral lesion.

The peculiar way in which alcohol transudes through membrane, its diffusive power as it is called, enables it to reach all parts of the body in an extremely short space of time; the result of which is that the picture, which I have drawn, of the gastric vessels, may be found in any other organ of the body. There is dilation with reduced power of contraction. This vaso-motor paralysis, so to speak, is more continuous as well as more complete in some organs than in others, and some forms of alcoholic drinks produce it much more certainly than others. This is the case if the alcohol be impregnated with some of its allies, especially amylic alcohol and fusel oil; these latter are always more or less present in potato spirit, with which wines are commonly fortified. The influence of these alcohols is very decided upon the nervous centres; they immediately produce some of those exaggerated forms of drunkenness in which violent excitement and maniacal delirium are manifest. They make the fluid pleasanter to the taste; and some of their forms are frequently added for the purpose of producing a so-called "bouquet." Their effects are far more serious and immediate than those which follow from the simple use of ethylic alcohol. Time fails me to do more than allude to this important point. It may be that some conditions of the body, which arise from a continuous soakage with alcohol, may enable it to change ethylic alcohol into some of the heavier forms

(a) Abstract of the Annual Ora delivered before the Medical Society of London, May 6th, 1878

fusel oil may be manufactured, so to speak, in the human economy itself. The odour of the breath of a dead drunk man is often more than the odour of alcohol, but upon this point chemists have not yet afforded any safe information.

It is uncertain whether the congestion arises from an immediate action upon the tissues of the capillary, or whether the first effect of the alcohol may not be on the nerve, or whether an effect upon the nerve centre may not also accrue, as well as a local effect be produced before vaso-motor paralysis can arise. It may, like the blush of shame or the pallor of fear arise from direct nerve influence, or it is possible that the blood, altered by the alcohol, may be unable to affect the nerve centre so as to exert its controlling influence upon the particular set of capillaries more immediately concerned, or it may act in different ways according as the membrane is or is not altered by the alcohol. Be it as it may in its first origin the effect is to interfere with the proper renovation and nutrition of the part, and to commence a disease of the particular organ affected. Dyspepsia is the first outcome of the use of stimulants, and as a sequence to a common result, viz., inflammation of Glisson's capsule, we may have so-called cirrhosis or fatty degeneration of the liver, and similar changes may take place in the kidney ; the heart and large blood vessels may suffer directly or indirectly ; the muscles may be destroyed, or the nerve tissue of the brain or spinal cord may be the parts which show the effect of the reagent first. Our periodicals teem with cases of disease which are clearly traced to alcohol as the exciting cause.

The fluids of the body may be very near to that point at which the specific action of alcohol may be made immediately manifest by setting up some symptom of nerve irritation as soon as the vaso-motor paralysis subsides ; just as in the case of water, the rise or fall of one degree in temperature is physically of no moment unless it be at 32 degrees Fahrenheit, so a glass or two of alcoholic drink is not immediatly of serious import unless the stage of saturation has been reached. Then an action analogous to crystallisation commences ; there is an aggregation of altered blood discs or of coagulated fibrine either in the nerve centres or glandular excretory organs, or the muscular tissue, or, indeed, in any part of the body towards which it may gravitate. The deposit sooner or later gives rise to a train of symptoms, some of which always are associated with the idea of over stimulation.

There is another class of disease not always so clearly identified with the exhibition of alcohol. I seldom meet with acute neuralgia in the total abstainer, whilst hysteria is in a great measure absent in those families whose ancestors have been perfectly temperate people. I have traced back several cases of strongly marked hysteria, and in all I have found a certain dependence upon alcohol, not only in the patient, but also in the patient's immediate ancestors. I have met with numerous cases of acute neuralgia in highly sensitive females ; it is generally styled agony in those who are hysterically inclined ; some declare that it is only relieved by alcohol, or chloral hydrate, or some other narcotic. The medicine allays the pain if given in sufficient doses ; but, as the effect of the dose goes off, the disease returns with still greater intensity, until, at length, the stomach rejects the remedy, or some other circumstance comes into play which causes it to be laid aside. The pain has then to be borne with for a time, but after two or three days of comparative abstinence the pain subsides and the patient is in comfort. There is then, from some accidental cause a transient return of pain ; the stimulant or the narcotic is again resorted to ; it relieves for a short time, but that relief is purchased by a return of acute pain ; there is soon afterwards another paroxysm, and the whole course is gone over again.

A close attention to numerous cases of this kind, both in high life and low life, has satisfied me that, so long as the alcohol is given, sufficiently in excess to induce moderate vaso-motor paralysis, there is relief from the pain ; but, as soon as that influence lessens, there is an aggregation of altered fibrine, microscopic in quantity, either in the capillaries which supply the sentient nerves, or in the nerve cell itself, which sets up an irritation, which is felt at the periphery of that particular nerve, and neuralgia results as a sequence to that irritation.

Many kinds of so-called rheumatism have a similar origin. The imbibed alcohol affects different parts of the cerebro-spinal nervous system, according as the result attaches itself, as altered matter to one or other class of nerve-cell, and neuralgia or rheumatism, or rheumatic gout, as they are often called, or even gout itself, is the outcome of the action.

The cases of neuralgic disease, to which I more especially refer, occur in highly hysterical constitutions, and are not generally accompanied by any cutaneous capillary congestion, except when neuralgic pain is absent. There is sometimes great mental power in this class of cases, a brilliant intellect or great genius, which only shows itself when the cerebral capillaries are congested, and the cutaneous system gorged with blood. These cases generally go from bad to worse, and end in suicide, or as general paralysis, or dementia. The tissue of the brain and spinal cord being subject to changes which correspond, in a great measure, with those diseases of liver and kidney which are induced by alcohol, a low form of inflammation is set up first, and after that atrophy from impaired nutrition or fatty degeneration, ending in so-called white softening.

There is also a class of cases, not so generally attributed to alcohol as a cause, which I believe to have their origin in its habitual use, which are due to spinal irritation, and are sometimes called spinal neuralgia.

If time would allow, I could detail to the Society numerous cases in which so-called rheumatic pains have continued month after month and year after year apparently relieved for a time by the use of stimulants ; but the use being always followed a day or two afterwards by renewed pain and general distress, and yet the amount of stimulant taken has been in no way excessive. In such cases I have omitted the use of stimulants altogether, and, after a few weeks of further suffering, the pains have subsided, and there has been a fair recovery. Once or twice I have suspected locomotor ataxy, which developed when the patient has persisted in the use of stimulants, but it has not done so when they have been given up. Such cases are generally associated with a lithic diathesis. However much we may try to cure them, we cannot succeed effectually unless we enforce total abstinence, even putting aside pharmaceutical tinctures. The plan is often given up by the patient too soon ; he finds that the pains are at first even more severe ; he becomes disappointed and low spirited ; then some acquaintance advises him that abstinence is doing him harm. He takes stimulants unknown to his doctor, he feels renovated by it, his pains are eased, and he falls back into his old habits before there is time to effect the removal from his body of the remains of former doses of his favourite drink. He is then quite convinced that the treatment is wrong and he will not continue it, whilst, if he had persevered a few days or weeks longer, he would have found relief and been on the high road to obtain a perfect cure.

These cases are allied to those of the habitual drunkards and so-called dipsomaniacs who are persons who have produced so much mischief in their nerve centres that they are unable to take even a moderate amount of stimulant without a catarrhal state of the stomach supervening, which at once gives rise to an irresistible drink craving from which they have no escape if they can obtain alcohol. In such cases there is always an altered state of blood vessel or some interference with the nutrition of the cerebral organs, such as a varicose condition of the arterioles or small veins in the nerve structure, the result of alcoholic excess, which is at once renewed by each application to the wine or spirit bottle. There may be a cirrhosed condition of some of the glands, or else a fatty

degeneration which is incompatible with healthy vigour. These conditions may be removed in their early stages, as well as all other morbid results which are not self-productive, if proper measures are taken to promote their removal. The first and most important step is the immediate and total abstinence from all kinds of alcoholic drink.

(To be continued.)

SOME REMARKS ON THE PREVALENCE OF SMALL-POX IN DUBLIN (a)

By THOMAS WRIGLEY GRIMSHAW, M.A., M.D.,
Fellow and Censor of the King and Queen's College of Physicians, Physician to and Lecturer on Medicine in Steevens' Hospital, Consulting Physician to Cork Street Fever Hospital.

(Continued from page 405.)

For the information with regard to details, I am indebted to the reports of the Local Government Board and the Registrar-General, together with special information presented by Dr. Sinclair, the able Secretary of the newly-established Vaccine Department of the Local Government Board, under whose supervision upwards of 20 per cent. of all the public vaccinations in the Dublin district are performed. I have also to thank the Sisters of Mercy at the Mater Misericordiæ Hospital and the Registrars of Sir Patrick Dun's Hospital for furnishing me with the number of small-pox cases admitted to these hospitals during the last fourteen years, and the Registrars of the Hardwicke, Meath, Steevens', and Cork Street Hospitals for supplementing the returns of the Board of Superintendence. The Registrar-General also kindly furnished, in advance, the number of births, and deaths from small-pox, in Dublin and Ireland for the last year. I regret that the Local Government Board declined to furnish me with copies of the unpublished returns of vaccinations performed in the Dublin Registration district by the dispensary medical officers during the last year.

The general indications of the figures for Dublin are the same as those for the whole of Ireland. In 1868-69 vaccination had become very low in Dublin; in 1870 a few cases of small-pox appeared, and slightly stimulated vaccination; in 1871 a considerable number of admissions to hospital further stimulated vaccination, but it was not until *after* the disease had become widespread in 1871 that vaccination became excessive (if I may use the term). Thus small-pox had reached its height before vaccination had reached *its* height. Now, to come more particularly to the present epidemic, we find that in 1876 small-pox became very active in the towns in the north of England in daily communication with Dublin and the other sea-ports on the east coast of Ireland. In July of that year small-pox was introduced into Dublin by the usual channels. A woman from Manchester was admitted to Sir P. Dun's Hospital on July 27, 1876, suffering from small-pox, and communicated the disease to another patient, who developed the disease in Clarendon Street, which became a centre of contagion. In another instance, a servant from Stoneyhurst College in Lancashire contracted small-pox in Liverpool, proceeded to Dublin, and was admitted to the Mater Misericordiæ Hospital as a case of fever on Sept. 13, 1876. This case also unfortunately communicated the disease to others. Thus, two foci of the disease were established—one on the north, the other on the south side of the city—both having originated by contagion introduced from Lancashire. The disease having been thus disseminated, gradually spread, and its progress may be easily measured by the number of patients suffering from it admitted to Cork Street Hospital as follows:—

1876—August, 1; September, 0; October, 0; November, 3; December, 5.

1877.—January, 8; February, 5; March, 7; April, 3; May, 4; June, 3; July, 2; August, 4; September, 2; October, 3; November, 8; December, 23.

1878—January, 19; February, 76; March, 106.

Comparing this with the admissions per month during the epidemic, 1871-73, as follows:—

1871—February, 1; March, 1; April, 7; May, 5; June, 7; July, 1; August 4; September, 8; October, 41; November, 59; December, 78.

1872—January, 81; February, 90; March, 97; April, 65; May, 59; June, 64; July, 34; August, 16; September, 7; October, 7; November, 3; December, 8.

1873—January, 2; February, 1; March, 0.

It appears that the present epidemic was slower in reaching formidable proportions, sixteen months having elapsed before the monthly admissions exceeded 8. In the previous epidemic, but eight months elapsed before a similar period of intensity was reached. Measuring the prospects of the present epidemic by what occurred in the last, we should be prepared to deal with a considerable number of cases during the next six months.

My experience of the present epidemic has been almost altogether derived from Cork Street Hospital, but having retired from active duty at that institution on the 31st of March, I must look to my successors for information relative to any peculiarities which may arise in future.

Up to the last day of March, the records of Cork Street Hospital show that, since the commencement of the epidemic in the autumn of 1876, 295 cases were admitted.

From these statements it appears that the percentage of each variety was—discrete, 44·0; confluent, 50·3; and malignant, 5·7, against 61·8, 31·7, and 6.5, respectively, in the epidemic of 1871-73. The mortality has also been lower than in the last epidemic, when the total percentage mortality was 21·6, against 15·8, shown above. Not only has the total rate of mortality been lower, but the mortality in each class has been less. The mortality among the confluent cases showed a marked reduction from 47·6 to 21·6. This is easily accounted for by the fact that of the confluent cases in 1871-73, only 60·4 per cent. where vaccinated, whereas, in the present epidemic 70·9 were vaccinated. In the discrete variety the mortality was, as usual, insignificant, one having died of consumption, the other of meningitis, and therefore died *in*, but *not of* small-pox.

Of discrete cases, 93·1 per cent. were vaccinated, and of these only 2 died, or at the rate of 1·5 per cent., neither of whom died of small-pox. There is a marked contrast among the confluent cases, of whom only 70 per cent. were vaccinated; of these, 32 died, or at the rate of 21·6 per cent., the rate of mortality of the vaccinated being only 9·4 per cent., while among the unvaccinated it was 51·1 per cent. Among the malignant cases we find that the mortality among the vaccinated was only 66·6 per cent. against 90 per cent. in the unvaccinated. Adding all classes together, we find that the mortality among the vaccinated was only 6·8 per cent. against 50 per cent. among the unvaccinated, proving how much the disease is mitigated by vaccination.

Up to the present there has not been any case admitted to hospital who has been re-vaccinated.

I think it may be interesting to consider, in a combined form, the information I have collected at Cork Street Hospital during the last and present epidemics.

Thus, of 1,041 cases, 591 were discrete, 385 confluent, and 65 malignant, or in the relative proportions of 56·8, 37·0, and 6·2 per cent. Of the 385 discrete cases, only 9 died, or at the rate of 1·5 per cent. Of the 385 confluent cases, the mortality was 37·7 per cent. Of the 65 malignant (purpuric and hæmorrhagic) cases, 55 died, or at the rate of 84·6 per cent.

In each variety the mortality of the vaccinated was much less than of the unvaccinated. In the discrete it was 0·5 per cent. in the vaccinated against 23·1 per cent. in the unvaccinated; in the confluent, 22·6 per cent. against 65 per cent.; and in the malignant variety, 71·0

b

(a) Being an abstract of a paper read at a meeting of the Medical Society of the King and Queen's College of Physicians.

per cent. against 97·1 per cent. The total result shows that among these 1,041 cases the rate of mortality among the vaccinated was but 9·7 per cent., while among the unvaccinated it was 64·9 per cent.

It will be observed the largest number of cases admitted were young adults between 15 and 30 years of age. Of children admitted under 5 years, only 41·6 per cent. were vaccinated; of those from 5 to 10, the vaccinated cases were 71 per cent.; and from 10 to 15, the vaccinated cases reached 80·4 per cent. It is a sad fact that of the cases admitted during the present epidemic, 32 were unvaccinated, although within the provisions of the Act of 1864.

I shall now consider what measures should be taken to avoid such visitations in future, and if possible to limit the extent of the present epidemic.

I have pointed out that the chief promoting cause of the present, as it has been of past small-pox epidemics, is the neglect of vaccination. The existing vaccination laws are loosely carried out—the local authorities abstaining from prosecuting parents for neglecting to have their children vaccinated or to bring them for inspection on the eighth day; and the unwillingness of the magistrates to inflict penalties on persons who have violated the law. When these faults are complained of, the general rejoinder given by the boards of guardians and the magistrates is—"Oh, the law is deficient. Give us an efficient law and we will administer it efficiently." Although this rejoinder is more of an excuse than a reply, yet it must be admitted that the vaccination laws of Ireland are in very many important particulars deficient, and the deficiencies are of a nature which do not exist in the laws at present in force in England.

These defects are as follows:—

(*a.*) A child may remain unvaccinated for a period of six months after its birth without its parents incurring any penalty. The period in England is but three months.

(*b.*) Public vaccinators in Ireland have no power to take lymph as in England, thus limiting considerably the lymph-supply.

(*c.*) There is no inspection of vaccination in Ireland.

(*d.*) The payments to public vaccinators in Ireland are so small that it is not worth their while to be zealous in the discharge of their duty.

More than a year ago a bill to remedy all these defects was drafted by the Council of the Irish Medical Association, and presented to the Government, as also a bill for consolidating and amending the vaccination laws in Ireland. No step has yet been taken to bring either of these bills before Parliament, although it is now several years since the vaccination laws in England were amended, and the medical corporations in Ireland have impressed upon the Government the importance of action in the matter. So far as the prevention of the present epidemic is concerned, legislation can have little influence, and hundreds of valuable lives will be lost before any new vaccination law can be passed. I cannot consider the defects in the law as a sufficient excuse for the culpable neglect of the boards of guardians to improve the existing laws, which at all events give power, under penalty, to compel vaccination within six months of birth, and require parents to bring their children for inspection on the eighth day after vaccination, so that the medical officers may be able to judge of the success of the operation. Before leaving the question of vaccination there is another point to which I wish to refer—namely, the absence of any complete published return of vaccination in Ireland. It is impossible at present to ascertain the extent to which vaccination has been performed in Ireland. In England complete returns are published by the Local Government Board, but only once a year. In Scotland returns are published quarterly by the Registrar-General. In Ireland the returns published by the Local Government Board are only of the successful vaccinations performed by the dispensary medical officers and the workhouse medical officers. I believe myself that the Scotch method is the best, inasmuch as it brings the state of vaccination more frequently before the public, and places it in conjunction with the returns of births and deaths. I believe if this question were brought under the notice of the Government that a remedy for the present defective returns would be provided either by the Registrar-General or the Local Government Board.

Besides neglected vaccination there are unfortunately other promoting causes of small-pox permitted to exist in Dublin, which do not require any new enactment for their removal:—

1. The disgraceful sanitary state of the city, as evinced by its high death-rate.
2. The want of proper sanitary organisation and supervision.
3. The want of proper means of removing infected persons to hospital.
4. The want of epidemic hospital accommodation. This is a great defect in hospital organisation in Dublin. There is, in fact, but one epidemic hospital in Dublin, and that not sufficiently large to cope with such an epidemic as the present. It is utterly contrary to all sanitary knowledge to receive patients suffering from such a disease as small-pox into the body of a general hospital building, as, I regret to say, has been done, in some instances with disastrous results. The expedient of providing temporary accommodation in each epidemic when it has spread to a sufficient extent to alarm the public mind, seems adopted upon the utopian idea that each epidemic will be the last. The present epidemic has brought with it the usual scramble at our hospital, the usual wait-till-the-last-minute policy at the hands of guardians, and will not terminate until either each person has taken steps for his own safety or very susceptible persons have been attacked.

Although this epidemic has been a year circulating in Dublin, although the Dublin Sanitary Association, more than a year ago, warned the authorities of the impending danger, yet not a move was made—except by the Sanitary Association—until three months ago, to provide for the sick, or stay the progress of the epidemic, under the foolish belief that efforts of the sort would produce "unnecessary alarm," and with the comforting assurance that small-pox had not "assumed an epidemic character."

ON ASTHMA.

By J. B. BERKART, M.D.,
Assistant Physician to the City of London Hospital for Diseas of the Chest.

(*Continued from page* 403.)

DEFINITION, PATHOGENY, AND ETIOLOGY.

II.—Immediate Causes.

The organic lesions previously described as forming the predisposition to asthma, are, it is needless to add, by themselves incapable of producing dyspnœa. Notwithstanding the textural changes of the lungs, respiration continues to be undisturbed, and this perfect freedom of one of the most important functions is mainly due to the beneficent activity of compensatory forces which here, as elsewhere, tend to the preservation of health, even under the most disadvantageous circumstances. Indeed, it may be said that the disease which inflicts the irreparable injury carries with it also the means of relief. However considerable the reduction of the breathing surface may be, such respiratory arrears as might be expected to result from it do not exist. They are, on the contrary, completely balanced, partly by the greater volume of the blood which the hypertrophied heart propels through the pervious capillaries, and partly by the supplementary interchange of gases that takes place in the dilated vessels on the bronchial surface, where a delicate epithelium hardly opposes an obstacle to that process. Even when the failing action of the heart frustrates to a great extent the present arrangement, there are nevertheless means by which respiration is carried on

without painful perceptions to the patient. For with the diminished oxygenation of the blood, the chemical changes become less active, and as the intensity of the respiratory changes is directly proportional to the vital energy of each organic element of the body, the supply therefore suffices for the demand. Such mutual adaptations lead to an adjustment that is perfect within *physiological* limits, provided only time is allowed them for the accomplishment of their end. Much error has therefore been propagated as to the influence of food and sleep upon asthma. The *normal* modification which these produce in the respiratory function has been constantly supposed to be an efficient provocative of dyspnœa. But the facts that seem to warrant this assumption have been falsely interpreted. The influence of food and diet in general will be subsequently explained. For the present it suffices to say that sleep, as such, is by no means responsible for the nocturnal appearance of the dyspnœa. Floyer imagined that his asthma was produced in that way, and many gratuitous theories have since then been advanced in support of his view as to the occurrence of the paroxysms at night. A causal connection between these events is so generally accepted that the fact of a dyspnœa rousing the patient from his sleep is supposed to be pathognomonic of a nervous disturbance. Hyde Salter thinks that sleep produces insensibility to respiratory arrears and that it exalts reflex action. (*a*) Physiology affords no evidence in favour of this theory. What is known of the subject is that, during sleep, respiration is retarded, and the absolute quantity of carbonic acid exhaled is diminished by one-fourth or even more. (*b*) But these phenomena indicate merely a temporary abatement of the vital energy in order that its activity may be increased through the day by the consumption of the oxygen that is stored up during the night.

Those compensatory forces, however, have their limits. They prove inadequate in the face of an additional obstacle to respiration. In the healthy an impediment to the interchange of gases is readily overcome by means of the reserve fund, so to speak, at their disposal ; but in the asthmatic that fund is exhausted by its constant employment, even under physiological conditions, to maintain the balance between expenditure and supply. Hence, under such circumstances, a slight cause produces a disproportionately great effect.

Thus, the accession of an obstacle, however trifling in itself, is sufficient to provoke an asthmatic seizure. This, like every other form of dyspnœa, is primarily due to a disturbance of the interchange of gases. The want of oxygen and the accumulation of carbonic acid excite the centre of respiration, and from this stimuli are transmitted to the respiratory muscles. The pneumogastric nerves lessen the resistance which the "nœud vital" opposes to that irritation, and they distribute the activity of the muscles in such a manner as to conduce to an efficient ventilation of the lungs. Section of the vagus, although profoundly modifying the respiratory mechanism, has yet no influence whatever upon the amount of work which in a given time is performed by the centre of respiration. (*c*) Nor has irritation of that nerve any effect upon the medulla oblongata, unless this be prepared for it by the gaseous contents of the blood. (*d*)

The dyspnœa peculiar to asthma is distinguished by its type. Expiration is relatively more difficult than inspiration. The reason is obvious. Inspiration is the result of muscular activity, so that the lungs yield to the traction which is greater than the resistance they are capable of offering. Expiration, on the contrary, is actively and mainly performed by the lungs themselves, and the want of their co-operation in this act cannot be fully compensated for by the aid of the auxiliary forces. Now, the predisposition to asthma consists of nutritive changes of the smaller tubes and of the air-vesicles. These portions of the organ are truly the *loci minimæ resistentiæ ;* they are the parts first and chiefly affected by noxious agents, and are thus readily disabled in the performance of their function. The intensity of the subjective symptoms is in a great measure attributable to the same cause. Even in the healthy, an obstacle to expiration produces *far greater* distress than one to inspiration, or to both phases. (*a*) But here, the lungs are, on account of their diminished resistance, widely distended, and this distension considerably increases the difficulty of expiration. (*b*)

The immediate causes of asthma are numerous and of various kinds, but all productive of the same results—obstruction of the bronchi. They are exhibited in the following table :—

I. Hyperæmia and œdema of the lungs.
  - *a.* Relaxative { Inhalation of irritating gases ; Inhalation of dust ; Thermal influence.
  - *b.* Collateral { Meteorismus ; Embolism of the pulmonary artery.
  - *c.* Reflex paralytic.

II. Bronchitis.

III. Stenosis of the bronchi { Foreign bodies. Compression.

I. *Hyperæmia and Œdema.*—The dilated capillaries, and more especially the vascular papillæ, which, as above described, project from the surface of the mucous membrane, are for various reasons greatly susceptible to fluxionary hyperæmia. Such turgescence readily causes occlusion of the bronchioles. The inspiratory traction, however, is soon increased in force, so as to enable it to effect the entrance of air into the lungs. The dyspnœa that nevertheless accompanies the hyperæmia is, therefore, due not so much to the absence of air as to the rapidity with which the blood passes through the dilated capillaries. There is no time available for the interchange of gases, and the blood thus arrives at the pulmonary veins in almost the same condition as it left the pulmonary artery. A similar process takes place in the parotid, in which, after section of the sympathetic, the blood in the veins presents the arterial character. The arterial system is thus supplied with blood imperfectly oxygenated. Meanwhile air continues to enter the lungs, whereas none, or very little, can escape from them. The thorax is gradually distended to its utmost limits, and is held in the extreme inspiratory position by the tetanic contractions of the respiratory muscles ; the stimulus to these contractions being furnished by the carbonic acid in the blood. When the dyspnœa has reached its climax, amelioration generally takes place. It appears that the carbonic acid in the blood causes contraction of the pulmonary capillaries, either by irritation of the vaso-motor nerves or of the vascular walls. (*c*) The current of the blood once being slackened there is now no obstacle to the ventilation of the lungs.

This form of hyperæmia is generally of short duration, and does not give rise to exudation. But when the left ventricle is incapable of propelling all the blood that by the increased afflux is brought to it, a passive congestion complicates the fluxion. In consequence of the greater pressure, serum now readily transudes into all the interstices of the lungs. Such œdema most frequently occurs in hydræmia, especially of parenchymatous nephritis, and arises also from the temporary increase of the volume of the blood by an excessive accumulation of fluid in the system. (*d*)

a. Relaxative.—Fluxionary hyperæmia is caused by

irritants, which act directly upon the muscles or the ganglionic apparatus of the blood-vessels and causes them to dilate. It arises from—

1. *The inhalation of irritating gases.*—Some asthmatics believe that the air of certain places is particularly obnoxious to them, and they attribute this injuriousness to subtle atmospheric conditions. There is no doubt that every open or confined space, every field, and every house in town and country, possess what may be called their own peculiar climate. But nothing justifies the assumption that the *normal* variations of the atmosphere are capable of producing dyspnœa, however delicate the bronchial surface may be. The mystery that surrounds these cases can, however, be readily solved; for when the "inscrutable differences of air" are responsible for the asthmatic seizures, their hurtful influence proceeds from the presence of irritating gases. Hyde Salter reports, (*a*) "Mr. C. has been asthmatic from his youth, and suffered at times severely; but for the last four years, during which he has lived in the same house, has had no attack. Last week he removed his residence about four or five hundred yards, to a higher spot, but more closely built round, and *very near to the exit of a sewer*; the third night he slept in his new abode he had an attack of asthma, and is suffering from a repeated attack at this moment." The exciting cause of this case is so evident as to need no mention; yet the conclusion that is drawn from it is that "the change of locality here was only a distance of four or five hundred yards, but it was sufficient to light up the disease that had been in abeyance for years." (*b*)

A temporary exposure to noxious gases, which, from decaying organic substances, or in the process of the various manufactures, are discharged into the open air, hardly produces an ill effect, because the space is so vast and the movement in it so continuous that those vapours are rapidly diluted, and thus rendered harmless. Dyspnœa, however, results when their ascent is impeded so that a quantity of them remains within the zone from which the inspiratory current is immediately drawn. In this way fog exerts its injurious influence on the diseased mucous membrane of the respiratory passages; for, besides ill-defined hydrocarbons, it contains large quantities of ammonia, of which Boussingault once found the enormous proportion of one grain in thirty-five ounces of the condensed water. (*c*) Considering that the injection of a few drops of ammonia into the bronchi causes the most intense pneumonia, the irritating effect produced by fog is readily intelligible.

The air of bedrooms, especially in the winter, proves, perhaps, the most frequent cause of the "nocturnal" asthma. Notwithstanding the diminished energy of all the vital changes during sleep, at least one thousand cubic feet of air pass every hour (*d*) through the lungs, and return from them charged with more than four per cent. of carbonic acid, and completely saturated with water vapour; and the expired air contains ammonia, probably from decayed teeth, or from particles of food decomposing in the mouth, also hydrogen, hydrocarbons, and sulphuretted hydrogen, which in consequence of a faulty digestion may diffuse themselves into the intestinal veins, and be eliminated by the breath. (*e*) The products of perspiration and those derived from the combustion of candles, lamps, or gas, contribute in their turn to increase the insalubrity of the place. It is known that the air which contains one per mille of carbonic acid is irrespirable, and its injuriousness is due, not so much perhaps to that gas itself—which when pure, may without harm indeed be inhaled in a somewhat larger quantity than is then present—but to the organic substances which always accompany it. Yet even a slight excess of the pure carbonic acid causes turgescence, a sensation of heat and pricking in the conjunctival and respiratory mucous membranes, while at the same time it increases the cutaneous and mucous secretions. (*a*) In the presence of organic substances, however, a much smaller quantity of it becomes highly irritative. The inflamed mucous membrance of the respiratory tract seems particularly susceptible to its influence, and Hauke is led to conclude that the coughing fits of pertussis are traceable to that source. (*b*) The manner in which the organic substances act is as yet obscure. If it were permissible to speculate on the subject, the dyspnœa, which they undoubtedly produce, may perhaps be attributed to the "oxysulphide of carbon," which, according to Radziewsky, (*c*) arises from putrifying organic substances, and is widely spread in nature. Radziewsky himself, on inhaling oxysulphide of carbon, immediately felt a pressure on the head, a tendency to vertigo, and constriction across the chest; there was, moreover, the sensation as if the air-passages were obstructed. He soon, however, recovered on exposure to the open air. Experiments on animals gave the same results—dyspnœa and great distension of the thorax. Now, however large a bedroom may be, a few hours' occupation of it will render it insalubrious in the manner just mentioned, unless the air be constantly renewed to the extent of at least two thousand cubic feet per hour and person. How imperfect even such ventilation must be, as regards the removal of the gaseous impurities, in comparison to their dilution out of doors, is evident from the fact that here more than six millions cubic feet of air are available for the purpose. (*d*) Unfortunately asthmatics, as a rule, adopt no measures for the supply of fresh air. They rely on natural ventilation, or persuade themselves, if this matter even receives their attention, that opening the door of the bedroom is all that is wanted. But the consequence of that neglect is that on account of the slow diffusion of gases (*e*) the patients are surrounded by the noxious exhalations which they themselves produce. As the temperature of the room is raised by respiration, foul gases from kitchen sewers and other sources are thus attracted into the room more readily than fresh air. After several hours, the atmosphere becomes so vitiated that respiration is impossible; so that towards morning the patient is roused from his sleep by an attack of asthma, and he is forced to seek relief at the open window.

Clinical Records.

ST. MARY'S HOSPITAL.

Compound Comminuted Fracture of Skull, with Exposure and Laceration of Brain—Suppurative Meningitis—Death.

Under the care of Mr. NORTON.

Notes by Mr. RALEIGH OWEN.

H. H., æt. 32, a labourer, was admitted on evening of March 13th. While firing an old gun, the connection with the stock gave way, and the barrel recoiled, the broken lock, on which blood and hair were afterwards found, striking him on the head. When seen, two hours after the accident, he was sensible, and could answer questions, but on being put to bed he became unconscious, passing an involuntary motion. On examination,

it was found that the right half of frontal bone was quite destroyed, the tissues being much torn and bruised, but there was no hæmorrhage. The dura mater was torn through, exposing a large surface of the anterior lobe of the brain, which was pulsating freely. Extending from this wound to above and behind the right ear, the bones were broken into many pieces; for the last 1½ inches there was another severe wound; from here three or four pieces of bone were removed, from the former wound eight or ten ranging in size from a penny to a pea, some being completely pressed on the brain: a small portion of brain substance also came away. When the brain was touched, the patient did not seem aware of it, but he was sensitive to the slightest touch round the orbit. The left pupil was insensible to light, somewhat dilated, conjunctiva not affected by touch; the right could not be examined. He could move in bed, turning his face from side to side; movement of legs and arms not impaired. Sensation on right side of face was intact, that on left quite destroyed. Both wounds were syringed out with carbolic acid, the edges brought together with wire sutures, and carbolic lotion applied to wounds. The hair was cut off, and ice bag applied to head. When shouted at, he would answer questions, but all the time kept up a conversation with imaginary friends. The pulse, which was slow and feeble, recovered under brandy. There was no sickness.

March 14th.—Very restless during night, and no sleep scarcely. Bowels confined and urine had to be drawn off. Pulsation of brain visible under skin. Puts tongue out slightly when told. No loss of sensation or movement in legs, but loss of both in left arm. Constant twitching of fingers. Answers questions like a man suffering from concussion. Skin acts well; temperature 99·8; pulse 68, hard and regular; respiration 17, deep; when pinched, makes remarks, mentioning names of friends. Complete recovery of sensation on left side of face. Very angry when lotion ran down his back, saying, in forcible language, "I wish you would not spit on me."

15th.—Passed water naturally. Had a quiet night. Wounds look healthy, and no discharge as yet; stitches removed. Talks rationally, and complains of headache. Temperature 104; pulse 120; respiration 28; pupils contracted, left especially so; pupil acts to light; movement of all limbs, but left side colder, and not moved with so much frequency or strength as right. Is in a dreamy half-sleepy state. During night said he wanted to get out of bed. When urinal was given him he passed his water. At 11 p.m. he was very restless, and pulse 135; four leeches were applied to forehead, after which he was quiet and slept. Motions passed involuntarily.

16th.—Seems rather better to-day, and talks. Some discharge from two small places; drainage tube inserted in side wound, from which a good deal of pus afterwards came. At night he was not so well, being very restless and delirious. Temperature risen from 102·6 to 105; pulse from 108 to 120; respiration 20. Subcutaneous injection of morphia given, after which he was quiet.

17th.—Not so well. Lies on his back with eyes closed. Does not answer questions. Right pupil dilated; left contracted. Total loss of motor power in left side, but perfect motion and sensation on right. Passes everything under him. Temperature 105·4. Free discharge from wounds.

18th.—Much worse. Temperature 105·2. Delirious during night; gradually became comatose, and died at 3.30 p.m.

Post-mortem showed effusion of blood and pus under temporal fascia. The brain exposed was irregular and pulpy, of a lemon colour, lined with yellowish lymph; much pus in pia mater. The right lower, and lateral, and upper surfaces of frontal lobes were quite disorganised—disorganisation extending for an inch into temporo-sphenoidal lobe; sides of right sylvian fissure were glued together. In the lateral frontal region of the left side there was a similar state as on the right for 1½ square inches. There was slight exudation in the pia mater. Dura mater stripped off very easily from posterior fossa.

The points to be noticed in this case are the following: the length of time before insensibility occurred; before its supervening the complete mental power he had, although his brain was injured so severely; the perfect recovery of sensation on the left side of the face on the day following the accident, and the return of consciousness. Subsequent inflammation of the brain was the cause of death.

Translations.

ON THE TYPHUS OF THE EAST. (*a*)

By Dr. Combey,

Late Principal Medical Officer of the Army Medical Department of France.

At the present time when all eyes are turned towards the East, it cannot but be interesting to cast a retrospective glance at the simplest means of purifying the air of hospitals, encumbered by feverish or wounded patients, and thus to prevent the contagious or infectious *materies morbi* spreading to those who are in attendance or in the neighbourhood.

To arrive at this important result, during the war in the East, 1856, when the military hospitals of Constantinople were cleared of the numerous typhus patients sent from the Crimea, the principal medical officer of the hospital at Pera thought it indispensable to adopt radical and energetic hygienic measures. This took place in 1856, at the beginning of February, but it was in March and April that typhus reached its *maximum* of intensity.

The patients filled all the hospitals of Constantinople, and especially that of Pera, which was one of the largest hospital establishments. About 12,000 patients were spread about. Pera contained 1,800 of the worst cases, chosen from the others, as they were near the place of embarkation.

To complete the medico-chirurgical staff at Pera, thirty-five medical men were selected, amongst whom were ten acting surgeons, at the head of which I was placed as principal of the first class. Seeing such a terrible mortality taking place amongst the physicians and patients, a conference of the acting officers was called, and I thus addressed them:—

Gentlemen and *confrères*,—You see, as well as I do, the serious ravages made by typhus, both amongst our patients and the medical men of Constantinople and the Crimea. We must then take radical hygienic measures to avert it, and make ourselves masters of this scourge if we do not desire to lose a number of our brave soldiers, or to die here like dogs. You know that our wards, of the height of 5 metres, contain four rows of beds, and that it is impossible to dispense with one, as we have not space to contain all our wounded and the fever patients who are daily sent from the Crimea. We must then supply for the insufficiency of space and pure air, by taking away the windows which open on the anterior gallery of the building. (The hospital was a square building, like the ancient cloisters, with a glazed interior gallery with a court in the middle).

The patients in the fourth row along the interior should have as pure air as those who are placed on the opposite side; but as the arcades are glazed and do not open, we must take out a pane in each; thus the air will be constantly renewed, and, as they are twelve metres in size, a good supply will be thus secured. At the same time, we must open night and day the windows looking on the country.

We shall thus establish in the superior part of our wards a current of pure air which, coming from the country, will escape by the windows in the interior court. This current will carry away the putrid and contagious *miasmata* coming from the patients suffering from typhus or wounds.

In the wards where the windows do not open, a pane of glass must be taken out, and when all the air has been changed as far as possible, we must employ aromatic fumigations and chlorinated lotions. The patients will not take cold as there is a good fire in each room, and they have warm

(*a*) *La France Médicale*, April, 1873.

woollen counterpanes. Moreover, these soldiers are not sensible to cold, as they have have slept in the Crimea, under tents, huts formed of branches of trees, or in holes dug in the ground.

Finally, we must place in separate wards all the typhus patients, and disinfect with sulphur the clothing of soldiers who have come from the Crimea and all the clothes used during treatment, in order to destroy both the *miasmata* likely to transmit typhus and the vermin.

My proposition was immediately adopted. It was certainly time to aërate our wards, since the mortality was so great in the hospitals at Constantinople and Pera from overcrowding; almost daily a military surgeon died in consequence of infection. The effect of this permanent aëration was so marked that our hospital, which was considered as the most infected, lost fewer typhus patients, proportionate to number, than any of the others, and not a single medical aide-major was attacked. None of our patients experienced any bad results from our permanent ventilation.

The disinfection was noticed by the captain who made his daily rounds at all the hospitals, and who was astonished on entering our wards, at not experiencing the nauseous and infected odour he felt in the neighbouring hospitals.

In 1854, there were numerous cases of cholera and dysentery at Pera, the former being isolated on the second floor of the hospital; but at the beginning of 1855 we determined on removing them to a separate establishment.

The wounded were generally placed on the ground floor, and the fever patients in the upper. There were stoves in each ward for the wet season, which was sometimes cold and humid.

Thus, during the first months of 1856 there was a heavy fall of snow which lay for five days before it melted. During the invasion of typhus, we noticed with pleasure flakes of snow in the wards, as it proved that the ventilation was thorough.

The hospital at Pera received 27,500 patients during the twenty-two months it was open. It was the first establishment created. Thirteen thousand patients were sent to France, or to some of the other hospitals in the interior to make room for those who were arriving from the Crimea. There were 5,040 deaths; each acting physician had daily charge of 130 to 200 sick. The admissions varied very much. Sometimes we received 200 or 300 a day, sending away as many to France or to the interior. Thus, after the attack on the Malakoff, we received 800 in one day, of whom 595 were Russian prisoners seriously wounded. In June, 1855, the period of the attacks on the Malakoff, we opened a special ward for officers, and the eighty beds assigned were very soon filled with wounded and fever patients. In the hospitals and through the army few officers died in the proportion to the soldiers and non-commissioned officers, whilst the latter furnished a lower death-rate than the privates.

In June, July, August, and September, 1855, before, and on the attack of the Malakoff, the largest number of wounded were transmitted from the Crimea. It is easy to imagine the large number of operations performed at Pera, especially after the murderous combats which closed the capture of Sebastopol. Thus, in 1855, we received 292 who had been operated on in the Crimea, out of whom 127 were sent to France, 56 recovered, and 109 died. Besides, 235 wounded underwent major operations at Pera, such as amputation, disarticulation, and resection. Out of this number, 81 were transported to France, 47 recovered, and 107 succumbed to secondary complications. From these figures it will be seen that the operations were followed by a high mortality for which it is difficult to account, except by the unhealthy situation. We must remember that all the patients sent from the Crimea were very debilitated, and almost all suffering from scurvy or anæmia. If local or general bleeding had to be adopted the patient very often succumbed. Now, during the major surgical operations, there was always a great loss of blood, from which the patients experienced great difficulty in rallying. We therefore arranged, that important surgical operations should not be performed without a consultation of all the acting surgeons, over which I presided, and we then decided, by the majority of votes, whether operative measures should be adopted or deferred to a more distant and favourable period.

The wounded were exposed after recovery to a malignant fever of a character *sui generis*, which carried them off in two or three days. Sometimes the treatment of the wounded was arrested by numerous complications, amongst which I may notice scurvy, anæmia, hospital gangrene, osteo-myelitis, diarrhœa, dysentery, intermittent, typhus, and typhoid fever, and abscess of the lungs or liver. The treatment of typhus was very simple: it consisted in evacuants up and down, laxatives, vinous and acidulated drinks, weak infusions of tea and lime, extract of bark, &c. At the same time we applied cataplasms over the abdomen, sinapisms to the inferior extremities, refrigerants to the head, sitz-baths, vinegar and chlorinated lotions. Blood-letting was abstained from, for the reasons mentioned above. The mortality was about 1 in 7 or 8, which is less than the mortality from dysentery contracted in camps and warm countries.

As regards the most efficacious prophylactic and hygienic measures for contagious or infectious disease, I am of opinion that permanent ventilation is the most powerful, as it affords pure and well oxygenated air to the patients and the attendants.

T. M. Dolan.

LORD EMLY ON MEDICAL REFORM.

The Limerick Board of Guardians adopted last week a resolution demanding, in the interest of the sick poor, such uniformity of examination as would prevent downward competition between colleges. They did so on the motion of Lord Emly, who, our readers will recollect, was Mr. Monsell, Postmaster-General under the last Government. In introducing his motion, Lord Emly said: Does the present system of appointment of poor-law medical officers reasonably secure competence? Many humane and charitable persons evidently suppose it does. They must suppose that all candidates for the office are competent to fill it, otherwise they would not be quite so ready as they are to promise their votes to candidates without inquiry into their qualifications; but their belief is founded on an entire delusion. True, by the regulations of the Local Government Board, every candidate must have a diploma—that is, a certificate of fitness to practice—from some of the bodies authorised to grant licenses or diplomas; but those diplomas in no way secure competency. I will explain to you why. There are in the United Kingdom 19 bodies whose diplomas entitle the holders of them to be placed on the medical register. These bodies receive a certain sum for each diploma they grant. The lower the examination the greater number can pass it; and the greater number that pass the larger the sum the body that grants the diploma receives. Suppose, for instance, that we had no standard for milk, and that each of the contractors who had tendered for our milk supply to-day was at liberty to serve in any quality of milk he pleased, the contractor who sent in the worst milk would receive the most money. What sort of milk would be got under this system? That is precisely what happens under the present system, or medical standard. The lower it is fixed by any of the bodies authorised to grant diplomas the more money will that body make. No doubt some of those bodies—I am happy to mention the University in Dublin Trinity College—do their duty honestly and conscientiously, but the students who are rejected at their examinations quickly find their way to the colleges where their examination is lowest and then get their diplomas. I have said that Trinity College did its duty. Lord Cairns, its Chancellor—now Chancellor of England—states that the difficulties which the University has had to contend against have arisen from different standards of examination elsewhere, and he would be glad to see an improved standard effected. A system such as I have described is indefensible. The military authorities show their opinion of it by not appointing anyone, no matter the number of diplomas. Any army surgeon is not appointed without his having passed a medical examination, conducted by an army medical board. The soldier in this respect is better placed than his father or brother residing in a cottage, and I ask why should not the poor man in his cottage have the same protection against medical incompetency as his son or brother in the army has? I have received a letter from a most eminent medical man, not belonging to this district, in which, after describing the present system of obtaining diplomas, he writes—"As far as my own experience goes, the ignorance of medical and surgical knowledge, either theoretical or practical, is truly deplorable. I found some who did not know the use of the most simple surgical instruments—for instance, a catheter—almost total

want of knowledge in midwifery, and yet having the Scotch midwifery qualification recognised by the Irish Local Government Board. Fever is not a necessary study; many who get medical and surgical qualifications, and afterwards get public appointments, never see a case of fever during their study." These are exactly the results we should expect from the system I have described. How should it be reformed? Common sense answered, by having examining boards for the United Kingdom, instead of having nineteen bodies authorised to confer diplomas, each having its own standard of examination. But powerful interests hold a different language, and I am afraid that common sense, unless it is supported by a strong expression of public opinion, is no match for powerful interests. Let us do our best to bring public opinion to bear on the question.

REGISTERED FOR TRANSMISSION ABROAD.

THE
MEDICAL PRESS AND CIRCULAR
Is published every Wednesday morning. Price 5d. Post free, 5½d.

POST FREE TO ANNUAL SUBSCRIBERS £1 2 6
„ IF PAID IN ADVANCE 1 1 0

*** Post-office Orders and Cheques to be drawn in favour of—
A. A. TINDALL, 20 King William Street, Strand, London, W.
A. H. JACOB, 3 Molesworth Street, Dublin.
MACLACHLAN and STEWART, South Bridge, Edinburgh.

SUBSCRIPTIONS FOR FRANCE are received by Messrs. BAILLIERE, Rue Hautefeuille, Paris—post free in advance, £1 3s. 6d. per annum.

SUBSCRIPTIONS FOR THE UNITED STATES are received in New York, by Messrs. WILLMER and ROGERS; Baltimore, by Messrs. KELLY and PIET; Philadelphia, at the *Medical and Surgical Reporter* Office, post free in advance, six and a-half dollars (£1 3s. 6d.) per annum; or direct from the Offices in this country for the same amount, if remitted by International Post-office Order.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, MAY 22, 1878.

THE BILL FOR THE REPEAL OF THE CONTAGIOUS DISEASES (WOMEN'S) ACTS, 1866-69.

IN anticipation of the second reading of Sir Harcourt Johnstone's Bill for the Repeal of these Acts, the City of London Committee have published and distributed broadcast their "Reasons" in support of that Bill. We shall have a better opportunity of making some remarks on the subject after the debate, which will take place this (Wednesday) evening in the House of Commons, but we may in the meantime draw attention to some of the arguments that have been advanced in favour of repealing these Acts.

The first reason is that "the Acts are conceived in the interest of immorality." In reply to this we would ask whether it was at all likely that a legislature, whose morality, integrity, and honesty of purpose are more remarkable than at any previous period of our history, would conceive an Act in the interests of immorality? But, say the committee, "that this is the object of the legislation is obvious from the fact that the Acts are applied to one sex only." It is, however, equally obvious that there would be many difficulties in the way of submitting men to the same examination as that to which prostitutes are liable. It might be desirable, but it is not practicable, nor does the principle on which the Acts were framed involve the subjection of our soldiers and sailors to the same measures of precaution as those to which the women in question are subjected. As we have remarked on a former occasion, the prostitute is a marketable commodity, which the soldier or sailor is not, and what is practicable or advisable in the case of the former is not practicable in the case of the latter. To illustrate our proposition by an analogous instance, let us take the Adulteration of Foods Act. There are two ways in which a check might be put upon the adulteration of food, namely, either by putting the purchaser on his guard and exercising some control over his conduct, or, on the other hand, by making the vendor answerable for the purity and innocuous nature of the goods in which he deals. For obvious reasons Government adopted the latter method; consequently any tradesman may be prosecuted if the inspector finds that the food is adulterated. In like manner, but by preventive rather than by punitive measures, the prostitute is for the present put under Government surveillance instead of the soldier or sailor who purchases the intercourse which he has with her, because it is more practicable for the Legislature to deal with her than with her paramour. It would be certainly just and advisable for the men to be placed under the same supervision, and no doubt this might be eventually managed. But legislation on any subject cannot be made perfect all at once, and it does not follow that because these Acts do not go far enough, they should therefore be altogether repealed.

Then we are told that "had the Acts been honestly framed to minimise or stamp out contagion they would have been universally applied, instead of being limited not only to one sex, but to certain naval and military stations, &c." Now this is taking a very unfair and unwarrantable advantage of the thoughtfulness and discretion of the Government, for the above procedure was adopted because the army and navy are under the immediate control, and constitute an important property of the State, and because it was anxious to try, in the first instance, the effects of these Acts in certain naval and military stations, before applying them to all, in order that they might be able to compare the relative prevalence of venereal disease in the protected and unprotected districts.

The second "reason" is that the Acts have been "framed in the interests of vice, and that they have outraged decency, morality, and the Christian sentiment of the country." To say that they have been framed in the interests of vice is, as we have shown, a scandalous imputation to bring upon any Government in any civilised country; while the rest of the allegation is an equally groundless assumption. It is said that "hundreds of committees and associations have been already formed to agitate for repeal." But that does not prove that any such agitation is called for. Rather the contrary, for if public decency, morality, and the Christian sentiment of the country have been so outraged, wherefore the need of "hundreds of committees and associations" to excite the

indignation of the virtue-loving society of the present day? Surely its sense of decency and morality would be enough to demand unanimously the repeal of these Acts, without the officious help of a number of intemperate agitators stumping the country in all directions, and persuading a lot of silly people to put their signatures to petitions, the subject of which they know nothing about. We are even told that "delicate women" have been forced to enter these committees, "as a duty which their consciences would not allow them to decline." If so, we cannot say much for the "delicacy" of those women who have not shrunk from—indeed, have taken a great interest in—a subject which might have been more delicately left to the consideration of the stronger sex. Another "reason" is that the Acts are "cruel, oppressive, and one-sided in their operation." The allegation with regard to their one-sidedness or their restriction to the female sex we have already answered; and as to their being cruel and oppressive, neither Sir Harcourt Johnstone nor any of his friends have been able to show that their enforcement has been attended with any act of cruelty, or that they are one whit more oppressive to the class for which they are intended than many other Acts by which Government seeks to protect society from certain evils to which it is exposed. For surely the soldier's courtesan is not that delicate-minded woman that she should consider herself outraged by a professional examination, which hundreds of virtuous mothers undergo at the hands of their medical attendants; and to characterise this examination as a "surgical operation which defies description" is a gross misrepresentation of the real facts of the case.

Then we are told, as we have been so often told before, that the Acts "violate the first principles of English constitutional liberty." There has been so much nonsense talked in behalf of the liberty of the subject, that the less the committee has to say on that score the better; and we shall confine our remarks on this "reason" to asking if these Acts are more despotic than the Vaccination Acts, the Factory Acts, and many other Acts, in which a certain suspension of the liberties of the subject is considered justifiable on the ground of public expediency, or of protecting certain classes from evils to which they would otherwise be exposed. Nor are the opponents of the Contagious Diseases Acts justified in saying that these Acts have "legalised espionage of the most objectionable description." That some kind of espionage must be practised is obvious enough, for otherwise the Acts could not be put into operation, but it is again misrepresenting the matter to say that this espionage is "utterly abhorrent to the genius of a free country, and on a par with that practised in the worst days of French administration;" and equally untrue is it to say that this espionage "involves inquiry into the private character of every woman, without exception, in the subjected districts." Were such really the case, the Acts could not be tolerated for a day by any one who had the slightest respect for the female portion of the community. But we are not aware of a single instance of an innocent and virtuous woman being subject to any such indignities as the above imputation would imply; and we feel certain that if there had been, those who are so strenuously agitating for the repeal of the Acts would have been only too ready to make capita out of the incident. Besides, it should not excite surprise if when Acts like these first come into operation a mistake should be unfortunately made, a mistake which no one would more deeply regret than those who were responsible for the Acts being worked in as delicate and harmless a manner as possible.

Lastly we are told that the Acts "tend to increase and intensify" the very evil for the removal or mitigation of which they are framed. The only answer we need give to this allegation is, that the actual benefit or worthlessness of the Acts is open to statistical proof, and to evidence of the most reliable nature. If they had any such tendency as that imputed to them, it stands to reason that they would soon die a natural death, and that there would be no occasion for "hundreds of committees and associations" to agitate for their repeal. According, however, to the most recent army medical reports, the evidence on the subject is, as we showed a few weeks ago, quite in favour of these Acts, and we have no doubt that if they are allowed a fair trial, the results of their operation will be of a still more satisfactory nature. Whether they are to have this trial will depend upon the fate of the Bill now before Parliament; but, for reasons which we have briefly advanced, it is to be hoped that the Legislature will not be induced to hastily abandon Acts which, notwithstanding a few imperfections, have already had a very beneficial operation upon the health of the army and navy.

ADMISSION OF WOMEN TO THE PROFESSION.

The Duke of Richmond, by introducing into the Medical Acts Amendment Bill clauses providing for the medical examination of women, has raised the question of the admission of lady doctors to the profession beyond the arena of dispute in which it has hitherto lain. He has given to the proposition the dignity of recognition by the Government, and he has left nothing now to be done saving to decide upon the means by which the incursion of the "gentle sex" may be facilitated. But the matters which he has left thus undecided, and which he has attempted to deal with in the clauses of his Bill, are in reality the disputed ground which the lady doctors have, as yet, found it impossible to cross, and we may expect that their progress through the doctor's outworks will still be vigorously and obstinately contested by those who have hitherto resisted the intrusion of female physicians. There are, no doubt, many who think that the ingress of women to the profession ought to be resisted as being a vital injury, not only to the pecuniary interests of doctors, but to the prestige of the profession, but the disciples of this creed are a small minority, and, though that minority is mainly composed of senior, and, therefore, influential members of our order, they are not of sufficient force to impede seriously the progress of the lady doctors. Taken in the aggregate, both the public and the profession are distinctly of opinion that the ladies should be afforded the amplest facilities for education and examination, so long as their education can be conducted with due regard to propriety, and without hindrance to male students, and so long as their examination is, in all respects, as full and searching as that to which male students are submitted.

This view is very emphatically expressed by the *Standard* in a recent leading article. It says, "if women are to have medical diplomas at all, there must be no difference between the examinations they have to pass and those undergone by men, however much they may be separated during the preliminary training. This is a question which is not to be got rid of by any side wind. Either women are to be admitted to medical diplomas on precisely the same terms as men or they are to be left out in the cold altogether. Whatever legislation takes place to amend the law concerning the medical profession, this fact must be recognised. However much we may sympathise with a different kind of examination for women, it would be absurd to offer it under the circumstances, for the old clamour would still go on, and the women so qualified would be in no better position than the midwives, for whose examination and registration provision is made in the very Act under discussion. Looking at the tone of the various debates which have taken place on this question during the last few years, and the action of more than one examining body on the matter, it is clear that sooner or later women will find entrance into the medical profession allowed them on the same terms as men."

Unfortunately, neither the lady doctors nor the Duke of Richmond seem to regard the matter from the point of view thus assumed by the *Standard*. The ladies, it is true, have always demanded absolute equality of education with male students, admission to the same wards, and instruction on the same cases and in the same classes as male students, no matter what might be the subject of the instruction; but when it comes to the examination, the Duke of Richmond, on their behalf, hastily abandons the principle of equality of education, and proposes to enact a different and less stringent test for females than that demanded from males. The Bill says (Clause 14):

"The examination rules (*i.e.*, the rules to be enacted by the Medical Council for all qualifying examinations) shall provide for the admission of women to the examinations, provided that . . *b*—they shall not compel a woman, in order to obtain such qualification as will enable her to be registered, to pass, *if she object to do so*, the same examination as men without any distinction on the ground of sex."

To such a provision we object most emphatically, and protest against the reception of women within the pale of our profession, except upon terms absolutely even with those to which we have ourselves submitted. Such an enactment would operate as a direct encouragement to licensing corporations to set up a sham examination with which to catch the diploma fees of the ladies, and we should not have to wait long for a college which would meet the views of the women students by cutting out of their curriculum and their examinations as many subjects as they might consider that female students would "object" to pass. Moreover, it would be contrary to every precedent, and in violation of every principle of justice, to permit a student to refuse "on the ground of sex," or on any other ground whatever, to answer questions put to him or her. It would be, surely, a ridiculous proposal that a male student should be permitted to decline to answer upon the anatomy of the female pelvic organs, the physiology of gestation, or upon obstetric surgery, and inasmuch as it would be impossible to debar women from any line of practice, once their names were placed on the register, it would obviously be improper to allow them to appear on that list, until they had been tested effectually upon all subjects to which their future practice might possibly be applied. The Duke of Richmond will deal most fairly with the troublesome problem which he has undertaken to solve, by removing every legal restriction which forbids a licensing body to grant diplomas to women, by forcing every such body to receive women students who display the same degree of competence as their male competitors, and by requiring the ladies to encounter the same education and the same examination in all respects as is required for masculine candidates. If this be done, the race for success in the practice of medicine cannot be fairly forbidden to those ladies who choose to try their luck. We may doubt their wisdom, but must not refuse them their rights. It is for them, not us, to weigh the following words of the *Standard*:—"Those concerned must face the probability that when once the novelty wears off, women who become doctors will find practice as hard to gain as scores of struggling practitioners of the male sex do at the present time. One or two lady doctors are novelties, and gain adherents for that very reason; but when once any woman can enter the profession they will find that they have been striving for what, commercially speaking, is not worth the fight. In this profession, above all others, women will probably find themselves worsted by men; for, however accomplished they may be as nurses, the work of the physician or surgeon demands powers of a far higher calibre, and the feminine aspirants to the honours of the operating theatre will soon find their level."

Notes on Current Topics.

The Inquest and Medical Witness System in Dublin.

It will be recollected that for many years it has been the system, in direct contravention of the law, yet nevertheless under the authority of the Corporation of Dublin, to pay a fixed salary to an individual practitioner for giving medical evidence in almost every case in which an inquest was required, to the exclusion of the testimony of the medical man who had attended the deceased person before or at the time of death. This arrangement was in direct violation of the Coroners' Act, which orders that the coroner shall call in evidence "a legally qualified medical practitioner being at the time in actual practice at or near the place of death," and that such practitioner shall receive a fee of £1 1s. in each instance. After continuous remonstrance against persistence in the illegal and objectionable system which has been in action in Dublin, the Council of the Irish Medical Association appeared, in the person of their then Chairman, Dr. Jacob, before the Public Auditor to resist the confirmation of the payments of salary to the coroners' standing witness. The Auditor having declined to disallow those payments, the case was removed by the Association into the Court of Queen's Bench, where it wa

argued for several days on an application for a *certiorari*. Eventually the judges gave judgment substantially in favour of the Association, declaring the payment of a salaried medical witness to be illegal and contrary to the policy of the law. The events which have since transpired have just been communicated to Dr. Jacob by the Auditor. Having received a notice from Dr. Jacob not to allow further corporation payments in the way of salary to the coroners' medical witness, the Auditor communicated with the Finance Committee of the Town Council, who, though anxious to maintain the arrangement which had been condemned by the Court of Queen's Bench, thought it wise to take counsel's opinion as to the safety of their doing so. The counsel selected was Mr. Walker, Q.C., who had appeared for the Auditor in the Queen's Bench proceedings. His advice to the Corporation was that the payment of salary must cease, and that the responsibility should be left upon the coroner to employ as medical witness the person indicated by the law; that, in his opinion, the coroner ought, as far as possible, to employ as medical witness the person in attendance on the deceased at time of death, and ought to pay whoever he employed the statutory fee of £1 1s.

Thus the salary arrangement which, in practice, restricted the medical evidence to one individual has been quashed. It remains for the Irish Medical Association to make sure that the medical witness shall be, as far as possible, the medical practitioner who is acquainted with the circumstances of the deceased's case, and we have no doubt their already fruitful efforts will be continued until the intention of the law is strictly and uniformly carried into effect.

Vaccination in Ireland.

In the House of Commons, on vote 16, for the English Local Government Board, with reference to medical officers' salaries being taken,

Mr. Gray asked what the remuneration was for vaccination in England. The gross sum for public vaccinators was put down at £16,000. He was under the impression that the remuneration to the profession in Ireland for a vaccination was much less than in England. At present there was an outbreak of small-pox in Ireland which was in great part to be attributed to the insufficient encouragement given to Irish practitioners for successful vaccination. He wished also to direct attention to the vote for £13,000 for medical inspectors in England. There were no corresponding officers in Ireland, and the profession had again and again remonstrated unavailingly against this. When an outbreak of any disease occurred in England, one of these medical inspectors was forthwith sent down. He investigated and reported, and the cause of the outbreak was remedied. They had no such provisions in Ireland, and they were much needed.

Mr. Sclater-Booth said he could not say what was the remuneration for vaccination in Ireland, nor could he answer for the defects of the Irish system, but in England by some means or another the payment for successful vaccination amounted to about half-a-crown, and he considered that the money was well spent.

We are glad to be able to supply the information respecting which the President of the English Poor-law Board gives us to understand that he knows little and cares less. The total sum paid to the 804 public vaccinators in Ireland, according to the latest parliamentary returns published in the Irish Medical Directory, was £6,748, being at the rate of £8 7s. 6d. per annum for each officer, in return for which payment they vaccinated very nearly 140,000 persons. Not a penny of this money, however, came out of the public funds, from which the £16,000 a year alluded to by Mr. Gray was granted for England. Every shilling of the money paid to Irish vaccinators came from the pockets of the local ratepayers, and the only Irish grant from the Treasury which can be placed on the same footing as this £16,000 is a sum of £400 a year, which used to be disbursed through the Dublin Hospitals Board for the maintenance of the Irish Vaccine Institution. That institution has been recently placed under the Irish Local Government Board, and its maintenance is expected to cost from £800 to £1,200 a year. The President of the English Poor-law, who sits in Parliament to represent such interests, may also learn with advantage that in England a public vaccinator receives 2s. 6d. per case, in Ireland only 1s. for the same work, and that in England that officer is in the position to earn a handsome additional grant for assiduity in vaccination—in Ireland no such boon is conceded.

As regards the grant of £13,000, made yearly for medical inspection in England, it is not inappropriate to mention that in Ireland only £1,492 is granted for the same services, and that the working of the Public Health Bill—a measure which Mr. Sclater-Booth will admit is as much needed in Ireland as in England—has always been a sham and a discredit to the country, simply because the official inspection necessary to make it a reality is refused. We can tell Mr. Sclater-Booth that it is so refused because the Treasury, which is so alert to grant £13,000 a year at one side of the Channel, declines point-blank to allow a shilling to be voted for sanitary inspection at the opposite side of the water.

It is gratifying at least to Irish vaccinators to know that the mouthpiece of Government considers a half-a-crown fee per case "well spent," and it will be a still greater gratification to them when we are able to announce that the Bill of the Irish Medical Association for the amendment of the vaccination law in these and other important respects has emerged from the pigeon-hole of the Irish Chief Secretary's office, where it was buried eighteen months ago, and has some chance of being considered by Parliament and by the Government.

"The Laws of Therapeutics."

In the current number of the *Practitioner*, Dr. William Sharp, F.R.S., a distinguished representative and exponent of the principles and practice of homœopathy, has a paper on the above subject which will doubtless for more reasons than one surprise the readers of that excellent journal. The paper is addressed to students and young practitioners, as "the ambition and uncharitableness of attempting to disturb the tranquillity of the senior members are not entertained; so that if any of these begin to read they are with submission requested to stop." We do not, however, think there was any fear of Dr. Sharp doing anything of the kind, at least if we may judge from his present paper, which in all probability will induce other readers to stop besides the senior members of the profession. It was very liberal of the editor of the *Practitioner* to admit into its columns the contribution of a homœo-

pathist, however eminent the writer may be, but we cannot say that Dr. Sharp has done justice to himself or has shown himself worthy of the generosity he has met with. The paper is all noise and smoke, amid which we are quite at a loss to discover the "laws of therapeutics." First, we have a definition of words, such as "phenomena," "general," "remedy," "induction," "deduction," &c. Then follow a few remarks on the "boundaries" of the subject, a few "particular facts" with regard to certain well-known actions of opium, aconite, digitalis, &c., and a few "general facts" or platitudes, such as, that drugs act locally, and that the kind of action is determined by the dose. Lastly, the "practical results" of this investigation, which justify the appearance of this paper in the *Practitioner*, are as follows:—1. The seat and kind of action of each drug must be discovered by experiments upon ourselves and others in health. 2. The drug to be given as a remedy must have been found to act in health on the principal seat or seats of the disease to be treated. 3. The kind of action of the larger doses of the drug, when taken in health, must resemble that of the disease, or at least the drug must have produced similar symptoms. 4. The dose given ought to belong to the range of smaller doses, which in health has a contrary action. 5. The drug must be given alone, otherwise its action will be interfered with, if not neutralised. 6. When the desired effect of the medicine has been obtained it must be discontinued. To what "investigation" Dr. Sharp refers we do not understand, nor can we, or perhaps any of our readers, see how the bare assertion of the above dogmata can justify their appearance in a first-class allopathic journal. We have no wish to be hard upon the homœopathists, and should have welcomed an able exposition of the "laws" of homœopathic therapeutics at a time when the medical profession are rather curious to know what the principles and practice of homœopathy really are, and whether they do not differ a good deal from the doctrines that were current fifty years ago.

The Bagot Will Case.

THIS extraordinary case was another proof of the contradictory nature of the medical evidence that is often given in our courts of justice. It is not the mere difference of opinion of which the public may justly complain, as there are, of course, questions on which a difference of opinion is both excusable and natural. It is that members of the profession so frequently give contradictory evidence on questions with regard to which they should, as scientific men, be practically unanimous. In this case a great deal depended upon the paternity of Mrs. Bagot's child, and upon the evidence as to whether or no Mr. Bagot was physically capable of being its father. Two or three physicians of eminence were of opinion that he was not, while others expressed an opposite opinion; and they had nearly all either seen or professionally attended upon him. The testator was not suffering from true paralysis, but from a disease which, according to the experience of Trousseau, and other writers on the subject, would not, especially at its outset, render it impossible for a patient affected with it to become a father. Dr. Radcliffe's evidence on this point was just what we might have expected from a physician who was practically familiar with that disease. "I have," he said, "two cases at present which are much more advanced in locomotor ataxy than Bagot's was when I saw him. They are unable to stir without help, and yet are the fathers of healthy children." This is the sort of medical evidence with which no fault can be found; evidence based upon actual experience, and not going further than that experience warranted. As regards this case, the fact is, Nature has taken care that that function on which the continuance of the human species depends should not be too easily abolished; and we feel certain that for physiological and clinical reasons—into which we cannot now enter—the profession will endorse the opinion which Dr. Radcliffe gave in favour of a lady who, with all her faults, has some claim upon the sympathy of the public.

The Views of Irish Boards of Guardians upon Conjoint Examination.

THE following petition to Parliament was recently adopted by the Limerick Board of Guardians on the motion of Lord Emly, and has since been accepted and signed by many Boards of Guardians in Ireland. Lord Emly, it should be observed, was Mr. Monsell, Postmaster-General under the late Government.

"That under the existing laws which regulate the practice of the professions of physician and surgeon in the United Kingdom, nineteen separate examining bodies are permitted to grant diplomas or licenses, which entitle their diplomatists to have their names placed upon the Medical Register of the Kingdom. That these several examining bodies have adopted various educational standards of proficiency for their pupils. That it has come to the knowledge of your petitioners that candidates who have failed to pass the examinations of one or more bodies who have adopted high standards of professional education have afterwards obtained the diploma of a body adopting an inferior standard of qualification. That in consequence of this great disparity between the highest and lowest standards adopted by the above bodies, her Majesty's subjects have no sufficient guarantee that a person whose name appears upon the Medical Register is thereby duly qualified to practise with safety the art of physician or surgeon. That such an existing state of the law is dangerous to the well-being of her Majesty's subjects, and more especially to the health of the poorer classes in Ireland who obtain medical relief at the public expense.

"Your petitioners therefore humbly pray that your noble house will change the laws which now regulate the granting of diplomas of license to practise the profession of physician or surgeon, and direct that in future there shall be only one examining body for the whole of the United Kingdom entitled to grant such documents, and that this body shall hold periodical examinations in England, Scotland, and Ireland alternately, and that upon this body all the several interests of the nineteen separate bodies who are now entitled to grant diplomas or licenses to practise physic or surgery shall be fully and duly represented.

"And your petitioners, as in duty bound, will evermore pray."

The French Association for the Advancement of Science.

IT is proposed to organise with special solemnity the annual session of the "French Association for the Advancement of Science," which will be held this year. The session was to have been held as usual in the provinces,

but the Association has decided on this occasion to assemble at Paris, thus to contribute to the *éclat* which the capital will present to strangers which the Exhibition will attract there. The annual meetings were formerly held at Bordeaux, Lille, Nantes, Clermont-Ferrand, and Havre, and were respectively presided over by Messrs. Quatrefages, Wurtz, d'Eichtal, Dumas, and Broca. That held at Paris will be presided over by M. Fremy; it will be opened on the 16th of August, and will last one week. The Municipal Council of Paris wishing to co-operate in this important scientific manifestation has deputed several of its members to unite themselves with the delegates appointed for the organisation of the congress.

The Small-pox in Dublin.

THE returns of the Registrar-General for the week ending May 11 show an increase in the prevailing epidemic, and we understand that those for the week ending the 18th will probably make manifest that the disease is rather on the increase than the decrease. The deaths in the week before last from zymotics numbered 44, being 15 over the average. Those from small-pox were 5 less than the previous week, but the cases in hospital were 16 more than the previous Saturday, being 254 against 238. The admissions during the week were 90 against 80 for the previous week. The total death-rate of the city was 30·2 per 1,000 of the population; the mortality of English and Scotch cities for some weeks being, London, 20·2; Glasgow, 23·0; Edinburgh, 21·7.

Sanitation in Birmingham.

WE are glad to see that a very promising movement has just taken place at Birmingham with regard to the future salubrity of that town. A public meeting has just been held in the town-hall under the presidency of Councillor Payton, to consider the advisability of forming an association for the diffusion of sanitary science, the undertaking of works connected therewith, and the selling of sanitary appliances. A resolution was carried in favour of the formation of a limited liability company. This is going to work in a very business sort of manner, but we are much afraid the company will not turn out a paying concern. It is not merely the question of getting shareholders, but of getting plenty of customers to deal in their sanitary appliances, and on these grounds we doubt whether the principles and practice of sanitation are sufficiently appreciated by the public to render the formation of a sanitary company a very promising undertaking.

The Mutual Autopsy Society.

THE French Association for reciprocity of dissection lost one of its members lately—Louis Asseline. His *post-mortem* obsequies took place a few days since. The *Gazette Hebdomadaire* says that the "sectio cadaveris" was made by Professor Broca, and the deceased was found to have died from rupture of the left auricle. It was remarked that the fronto-parietal sutures were not ossified, as one would expect to find them in a man of 49 years of age, and of a less cultivated mind. This ossification of the anterior sutures of the cranium is produced rather in the lower races than in white skinned people. If the fact observed in the case of Asseline comes to be verified in other persons who practice intellectual professions, we may conclude with certainty that it is their cerebral activity which causes the delay in ossification.

Death from Methylene.

A FATALITY from the inhalation of methylene is announced, the victim being a retired officer of 40 years of age, in apparently perfect health. The death was perfectly sudden and inexplicable, and it shows that this anæsthetic is, like chloroform, a poison to some persons of a peculiar idiosyncrasy, and will cause death without any apparent physical reason. We should be glad to know whether anyone can produce a death during ether inhalation for which the cause was not evident upon examination, and most frequently before death. We believe not. Deaths have occurred where patients with emphysematous or obstructed or solidified lungs have been dosed with ether and have died in consequence, but no fatality, so far as we know, in any case in which the administration could—upon previous examination—be considered reasonably safe.

Morphine Mydriasis.

AT a recent meeting of the Biological Society of Paris, M. Picard contributed a note on the Mechanism of Contraction of the Pupil produced under the Influence of Morphine." He attributes it to paresis of the sympathetic nerve, for if the sub-maxillary band is bared and a small vein opened, a flow of blood is increased after an injection of morphine. From this phenomenon he concludes that morphine produces diminution of power of the great sympathetic nerve.

Adelaide Hospital, Dublin.

THE Medical Board of the Adelaide Hospital has elected Dr. Kendal M. St. John Franks to the surgeoncy of the hospital, vacant by the resignation of Dr. Albert Walsh. Dr. Franks is an ex-scholar of the University of Dublin, and a gold medallist of the Dublin Pathological Society. He is also a demonstrator in the School of the Royal College of Surgeons, and surgeon to the Throat Hospital in York Street.

IN the principal foreign cities the annual rates of mortality, according to the most recent official weekly returns, were, Calcutta 45, Bombay 43, Madras 48, Paris 26, Geneva 27, Brussels 27, Amsterdam 26, Rotterdam 27, The Hague 26, Copenhagen 24, Stockholm 30, St. Petersburgh 63, Berlin 31, Hamburg, 29, Dresden 24, Breslau 32, Munich 32, Vienna 33, Buda-Pesth 50, Rome 33, Turin 32, Venice 32, Alexandria 35, and New York 24. Thus, London stands out as the most healthy of the principal cities to the world. The 807 deaths in St. Petersburgh included 142 from typhus and typhoid fever. Cholera caused 87 deaths in Calcutta, and 32 in Bombay.

WITH the genial weather of the past few days, the mortality throughout the United Kingdom has resumed its normal character, scarcely an excessive death-rate being observable in any large town. London is now at

20 per 1,000, Edinburgh 22, Glasgow 23; whilst Plymouth has fallen from 33 to 22, the other great centres showing also clean bills of health.

One or two changes have occurred during the last few days in the staff of the Westminster Hospital. Mr. George Cowell, F.R.C.S., has been appointed Treasurer, Dr. Allchin, Dean of the School and Lecturer on Physiology. The latter appointment is vice Maclure resigned. Dr. Murrell succeeds Dr. Allchin in the lectureship on Practical Histology.

Sir Sydney Waterlow, Treasurer of St. Bartholomew's Hospital, is of opinion that the recent Mitchell bequest of £70,000 to the sick poor of London, could not be better invested by the city authorities, than in founding a convalescent home in connection with all the Royal Hospitals; an idea which was loudly applauded at the St. Bartholomew's Annual Dinner.

Sir James Coxe, M.D., Commissioner in Lunacy for Scotland, has just died, at the comparative early age of 67. Deceased received the honour of knighthood in 1873, and was a magistrate for Midlothian, his native county.

University College and Hospital have come in for a very heavy windfall. It will be remembered that Sir Francis Goldsmid, who met his death by a railway accident a few days since, was Treasurer to this institution, to which he has left a bequest of £50,000.

Small-pox is still prevalent in London, where 48 died from this disease last week, no other death from this cause is reported throughout England and Wales. Of these 48 deaths 21 were certified as of unvaccinated persons, 13 vaccinated, the remainder being uncertified.

Medico-Parliamentary

NOXIOUS VAPOURS.

In the House of Lords on Friday last, Lord Winmarleigh asked the noble Lord opposite (Lord Aberdare), who had presided over the Commission appointed last year to investigate the subject of noxious vapours, when the report of the Commission would be presented.

Lord Aberdare regretted the delay that had occurred. The Commission had had to visit various parts of the country, and they had taken a great mass of evidence. The report was in process of preparation, and no time would be lost in presenting it.

MEDICAL OFFICERS AT WOOLWICH GARRISON.

In the House of Commons on Thursday last, Colonel Stanley informed Mr. Meldon that the garrison at Woolwich had its full complement of medical officers. No private practitioners were employed there. Some other garrisons were short of medical officers; that was in some measure due to a number withdrawing temporarily for purposes in connection with the training of the army corps at Aldershot. The sum of £5,000 was taken for the employment of civil surgeons at the Cape, as that was found to be more economical and desirable than the augmentation of the staff.

THE MEDICAL REFORM BILL.

IMPORTANT DEPUTATIONS.

On Saturday last a deputation from the Medical Reform Committee of the British Medical Association, and from the Council of the Irish Medical Association, waited by appointment on His Grace the Duke of Richmond in order to confer with his Grace upon the Medical Acts Amendment Bill. The British Medical Association was represented by Dr. Wilkinson, its president, Dr. Waters, of Chester, Chairman of the Medical Reform Committee, Dr. Chadwick, Dr. Carpenter, of Croydon, Dr. A. P. Stewart, and Dr. Manby. The Irish Medical Association was represented by Dr. Grimshaw, Chairman of the Council, who would have been accompanied by Dr. Robert MacDonnell, President Designate of the Association, but for an unavoidable hindrance.

The principal object of the deputation was to impress upon his Grace the propriety of direct representation of the profession in the General Medical Council, and of making the proposed conjoint examinations compulsory. These two points have been adopted by both Associations as the leading characteristics of their proposals, and Dr. Waters was able to state that in favour of these suggestions more than 5,000 members of the British Medical Association had expressed their feelings, while only about 200 took a different view.

After a full statement of the opinions of the British Medical Association by Dr. Waters and other delegates, Dr. Grimshaw addressed his Grace and pointed out that the propriety of conjoint examination had been already fully enunciated by almost all the Irish licensing bodies, and that it was only on questions of detail that the negotiations for the completion of such a scheme broke down.

The Duke of Richmond eventually replied to the deputation, and was understood to express an opinion distinctly unfavourable to direct representation as a practicable measure, though admitting to a certain extent the propriety of it on general grounds. As to conjoint examination his Grace stated that he was prepared to consent to making that measure compulsory upon licensing corporations, and would introduce an amendment to the 15th clause of the Bill to that effect. He was not prepared, however, to consent to the application of a similar compulsion to Universities, and in his opinion these institutions should be prepared to continue to give degrees as heretofore.

On Monday afternoon an influential deputation, representing the Medical Defence Association, waited upon his Grace the Duke of Richmond and Gordon to state the views of the Association with respect to the new medical Bill. Amongst those present were Dr. Richardson, F.R.S., President of the Association, Dr. C. G. White (Snodland), Vice-President, Mr. John Gay, Dr. J. Stevenson, Dr. H. W. Williams, Dr. W. Beech Johnstone, Dr. Hugh Adcock, Dr. W. Smith, Mr. J. Wallace Mason, Mr. Bott, Mr. Pridham, Mr. Alderson, Mr. George Brown, Hon. Sec. to the Association, and others.

Dr. Richardson on behalf of the deputation presented a memorial, which had been drawn up by the Council of the Association, pointing out that in any measure of medical reform one of the first principles to be enforced should be that no person shall in future receive a license to practise medicine or surgery in the United Kingdom, who has not satisfactorily passed a full and complete examination in medicine, surgery, and obstetrics; further, that there should be but one licensing board in each division of the kingdom, that the examinations of each board should be of one uniform standard of severity, and that the certificate or diploma thereafter granted, in each instance should confer similar rights and privileges. The examining boards should be appointed by the General Medical Council, which body should have the power of regulating the nature and scope of the examinations.

The Council also recommend the retention of the General Medical Council to superintend medical education, and that it should also be the duty of that body to enforce the laws relating to medical practice, especially those directed against the practice of medicine by unqualified persons, and the assumption of medical titles by those who are not registered.

It further expressed an opinion that it is imperatively necessary to make some radical changes in the mode of election of the members, and in the constitution of the General Medical Council. At the present time the profession as a body is not represented on that Council. This, in the opinion of the Association, is most unjust to the members of the pro-

fession by whom is provided the whole of the funds for the support of the General Medical Council.

With respect to clause 22 of the Bill relating to the unauthorised assumption of titles by unqualified persons, the Council approved of the proposed amendments, but suggested that the assumption of an unregistrable medical title after the passing of this Act should be deemed an offence punishable in the terms of the clause; also that a similar penalty should be inflicted on persons who practise medicine or surgery for gain, without being duly qualified, whether they assume titles or not. The clause of the bill as it stands would be wholly inoperative as regards the practice of medicine and surgery by unqualiffed persons, as long as they avoided taking or using any medical title. Unless the clause be amended to cover such cases great injustice would be done to the profession, and the public would be left unprotected if, as is proposed, the power to prosecute unqualified practitioners in England and Wales now possessed by the Apothecaries' Company be abolished. After a few remarks from Mr. George Brown, his Grace assured the deputation that he was as anxious as the members of the Association could be to stop unlicensed practice, and if the Council could draw up any clause that would satisfactorily meet the case, and send it to him before the Bill passed through committee, he would if possible adopt it.

It will be observed from the foregoing brief report that the Government is determined, if possible, to maintain the "family party" in the General Medical Council, and to protect the Universities in their degree trade at the expense of the corporations. We altogether deprecate both of these procedures, but we attach much less importance to the former than to the latter. The General Medical Council never exercised any really strong influence upon medical education and examination, though it took credit to itself for all the improvements in medical education which the growth of public opinion forced upon the licensing bodies. It looked on while the advance in scientific thought within our profession compelled colleges to march behind the progress of medicine; but it never initiated or carried through one single material change in the existing methods of education or examination. In the absence of the new blood which the profession desires to infuse into it, the General Medical Council will, no doubt, continue placidly to look on and to gratify itself with an annual *caucus*, but it will probably do no more for better or worse, and should we fail to carry out our transfusion project, we must be content with that body as it is. We need hardly resist the Duke's Bill, because it does not give us direct representation, but his Grace's proposal in reference to conjoint examination is a different matter.

That proposal must be resisted with all the energy of the profession, for, however much we may desire reform, however anxious we may be to help the Duke's Bill through Parliament, we cannot accept medical reform on such terms as would be worse than that which we desire to amend. The exemption of the Universities from conjoint examination schemes would be fatal to every principle of equity and to the object which the Bill aims at attaining. Some of the Universities, be it said with awe, are far from being superior to the temptation of underselling colleges in curriculum examination and fees in order to catch graduates. Some of them need compulsion just as much as the corporations, and already several of them are in hot competition with those much-abused institutions for the diploma fees of students. In Ireland, for instance, a compulsory conjoint scheme from which the Queen's University would be exempted would be simply destructive to the corporations. Already that University gives for £5 a degree equivalent to that for which the College of Surgeons charges £26 5s., and, in fact, the severest competition with which Irish colleges have to deal is that of the Q.U.I. In what position then would the corporations be if forced into a one-sided conjoint examination? Being dependent for their existence solely on the fees of candidates, these bodies *must* charge a substantial diploma fee, being under the compulsion of the Medical Council they *must* exact a substantial curriculum, and submit their candidates to a substantial examination. The Universities, on the other hand, if exempted, being independent of pecuniary considerations, may give their degrees for anything or nothing, may require what curriculum they please, and hold examinations agreeable to their own interests. No material benefit would accrue to the public from such an arrangement, for the diploma market, which is now divided between the nineteen licensing bodies, would still continue to extend amongst these conjoint boards and eleven Universities. We trust his Grace will think better of such a proposal.

Literature.

LECTURES ON SURGICAL PATHOLOGY AND THERAPEUTICS. (a)

Some eight months ago we noticed the first volume of this work, in which we found the various subjects treated were delivered in twenty-three lectures. These, again, were divided into twelve chapters—423 pages in all—and were illustrated with something over seventy woodcuts.

The second volume is now before us, and we find that a somewhat similar style is adopted, the subjects treated being delivered in about twenty-seven lectures, which are again divided into ten chapters, with copious appendices on chapters xvi. and xvii. treating on some affections of the bones and joints.

We also find the volume is illustrated here and there with upwards of a hundred woodcuts, which, on the whole, are good, and depict fairly the pathological appearances aimed at.

At page 218 we notice a woodcut representing a woman suffering from a very aggravated form of osteomalacia (after Morand). This same cut we remember having seen in Miller's Surgery as illustrative of the case of Madame Supiot.

At page 322 cirsoid aneurism of the scalp is well and faithfully represented.

In taking a general *résumé* of the work the reader might be inclined to think from the title that the remarks would be entirely confined to pathological and therapeutical research, which, no doubt, was the primary aim of the author, but it will be found that occasionally the line of demarcation between the surgery and the surgical pathology of the question is not so distinct, and, therefore, the author gives a very full explanation of the operative procedures and various lines of treatment recommended in certain surgical affections. We rather approve of this plan, as it may help to modify the general dryness and what we might call stiff and hard-to-be-remembered matter apparent in works on pure pathology. We are glad to find the same care bestowed on this volume which we drew attention to in the first part of the work, and we give the translator every credit for the efficient manner in which he has accomplished his task.

The first chapter of the present volume is taken up with the consideration of the Traumatic and Inflammatory Complications which may accidentally befall wounds. Then the affec-

(a) "Lectures on Surgical Pathology and Therapeutics." A Handbook for Students and Practitioners. By Dr. Theodor Billroth, Professor of Surgery in the University of Vienna. Translated from the Eighth Edition, Vol. II. Published by the New Sydenham Society. 1878.

tions which may supervene upon wounds and inflammation nests are fully and carefully considered.

Chapter xiv. opens with the consideration of Chronic Inflammation, especially of the soft parts.

At page 130 the chapter on Ulcers will be found, and we approve of much that has been said on this subject, particularly as regards some modes of treatment, for in speaking of skin-grafting Billroth says, "Transplantations of epidermis on Reverdius' plan are made with advantage for accelerating the healing process, but it unfortunately often happens that these transplanted portions of skin, after they have healed well, and the whole ulcer cicatrised again, perish, and so the greater part of the advantage, gained with difficulty, is lost anew."

The pathology of bone and joint disease is well given, and at page 244, when talking of the relative advantages that follow resection of the elbow and knee joint, he says—"In the case of the former the resection of this joint (the elbow) is not more dangerous than amputation of the upper arm. After resection we generally have, in favourable cases, a tolerably useful joint after spontaneous healing; almost always anchylosis." Furthermore, he says—"Very different is the state of things as regards the *knee-joint*. The resection of that joint is a more dangerous operation than the resection of joints hitherto mentioned, and about equals, in that respect, the deep amputation of the thigh. After resection of the knee-joint, all we hope to attain is anchylosis, which also results from spontaneous healing of the joint. This operation, therefore, since it does not effect more with a considerable amount of danger than what may also be effected by non-operative surgical treatment, if the process comes to a standstill, must only be undertaken when necessary for the saving of life. Hitherto I have but seldom determined upon the operation on account of caries of the knee-joint, whether amputation or resection. Only when every kind of treatment has remained useless for years, and the patient has become emaciated, and suffers greatly, can there be any question of amputation, or in the case of old people, in whom the cure of highly-developed caries of the knee-joint is improbable. A resection can only be performed with success in young subjects with a good constitution; it is generally only a means of accelerating the healing process in cases in which the chances are comparatively good." Further on Billroth says—"Other surgeons hold very different views on this subject, and in England, especially, resection of the knee-joint is thought so highly of that the operation is performed very frequently there, and in early stages of the disease, many German surgeons will, I believe, agree with me on this point. Others occupy a middle position, and judge more favourably of resection of the knee-joint after a few such operations have proved successful." Our views on this subject are in such strict accordance with Billroth's that we may be pardoned for giving his observations *in extenso*, for we have frequently seen young impetuous operators use the knife where, most probably, Nature and patience would have effected a far better result.

Chapter xix. opens with the consideration of Congenital Deformities of the joints, and the subject of distortions generally, this chapter being divided into four sections. At page 300, on the subject of the Essential Paralysis of Children, we think Billroth too brief in his remarks, considering the importance of the subject.

The chapter on Varices and Aneurisms is good, and we notice that Billroth appears to be conscious of the labour of the many surgeons who have devoted attention to this subject. He also gives a list of authors referred to at the end of the work.

On page 339 the very important subject of Tumours commences, and Billroth seems to be aware of the difficulty that sometimes occurs in arriving at a correct diagnosis. This chapter, we would say, was the most replete in the work. Every variety, appearance, manner of growth, is given with great exactness of detail. In his concluding remarks he says, "I cannot wonder if all I have told you about tumours is at present somewhat perplexing to you; it may possibly console you to know that I was not less perplexed when I was in your present position. Nothing but a longer study of the subject, and practice in diagnosing the various varieties of tumours which this *Clinic* affords has made it possible to speak with any degree of certainty on this difficult subject. . . . . I can only advise you, after every time you see a patient in the wards with a tumour, to go home and read up the case, and to compare the individual case with the general characteristics of tumours which I have pointed out to you. After having done this for some time, and after having examined under the eyes of your teachers into the pathological histology of all the tumours you meet with, you will soon get a clear view of the subject, and the various peculiarities of each will then become fixed in your memories."

Chapter xxii. treats on the subject of Amputation, Exarticulation, and Resection. By his remarks Billroth proves himself to be a sound practical operator, and a firm believer in the true principles of conservative surgery.

At page 507 he says—"In the performance of amputation and exarticulation it is, above all things, important (1) to perform the operation with as little loss of blood as possible; (2) to arrest the hæmorrhage so completely that there shall be no fear of secondary hæmorrhage; and (3) to cover the bony stump so thoroughly with soft parts that the latter may easily and completely heal and unite over it."

We have now fairly mentioned all the advantages of the work. It is, however, not without a few defects, which must necessarily exist, considering the vast amount of matter it takes the reader over. In the case of Hydrophobia, Tetanus, Glanders, the pathology of these important subjects is given in a very brief and contracted manner. Very much more, we think, might be said, considering our present information, about those diseases as regards the pathology and treatment during life.

In conclusion, we strongly recommend the work to the consideration of those requiring a clear insight into the subject of Surgical Pathology and Therapeutics.

LITERARY NOTES AND GOSSIP.

We hear that Dr. Milner Fothergill, whose excellent course of lectures on the heart have recently appeared in these columns, has a second edition of his work, "The Heart and its Diseases," in the press.

* * *

Professor Witkowski's *Anatomie Inconoclastique* is said to have met with such encouraging success in this country as a French work, that the publishers have determined upon issuing an English edition forthwith. Dr. R. Hunter Semple, author of "A Manual of Diseases of the Heart," &c., is engaged upon the translation.

* * *

Mr. Wm. Gilbert will contribute an article in the forthcoming number of the *Contemporary Review*, "On the Past and Present State of the Medical Profession."

* * *

The late Mr. Alfred Smee, F.R.S., surgeon to the Bank of England, was known to have some literary works in hand at the time of his sudden death. These are shortly to be brought to light in a biography of the deceased surgeon, with a collection of his miscellaneous writings on scientific and social subjects.

* * *

A chapter on the "hygienic influence of plants in rooms" will be included in the forthcoming "illustrated edition" of Mr. Francis George Heath's "Fern Paradise—a Plea for the Culture of Ferns."

* * *

Dr. Berkart, whose excellent papers "on Asthma" have been appearing in these columns during the past two or three weeks, has published a demy 8vo work of 264 pages on the same subject during the past few days. Mr. Reginald Harrison, surgeon to the Liverpool Royal Infirmary, has also published a work of about the same size, with copious illustrations, "On Stricture of the Urethra." We reserve our criticisms on these works for the present.

* * *

The fifteenth anniversary festival in aid of the Press Fund on Saturday evening was a great success. So great a number of literary celebrities has not often been brought together, and Lord Salisbury greatly distinguished himself in the chair by his urbanity and tact in a trying office before such company. He was well supported by the humorous *apropos* speech of Count Beust, the Austrian Ambassador; the sensible remarks of the Prince Imperial of France, and other speakers. Dr. Richardson, as representative of the literature in the medical profession, was present, and proposed the health of the artists who had given their services to heighten the enjoyment of a very pleasant and instructive evening.

Correspondence.

PERMISSIVE SUPERANNUATION.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Under the above head, I read in your columns a few weeks since, a letter showing the necessity of further ventilation of the above subject, with the view of establishing a more uniform and liberal estimate on the part of boards of guardians of the services of their worn-out medical officers.

It it to be feared in the present state of the finances of the country, with steadily increasing taxation, any considerable change in a compulsory direction is hardly to be expected.

In the interests, however, of the sick poor, whose requirements ought not to be overlooked, and at the same time in justice to one or two classes of the poor-law medical officers, I am of opinion the authorities might be induced to action; viz., *first*, where a medical officer has from arduous duties and long services, say twenty years, and sixty years of age, or nearly so, and whose health, mental or bodily, does not admit the due discharge of the duties devolving on him, that he shall be submitted to a careful examination by a medical board (nominated by the Local Government Board), consisting of three or four medical men of standing in their profession, presided over by the medical commissioner, this board to meet once a quarter to hear and decide on such cases as may be presented; their decision to be a guide to action on the part of the Local Government Board. Secondly, that numerically small class of medical officers who have been twenty-five years in office, and attained the age of seventy years, they shall be declared physically incapable of discharging their duties, and be called on to resign their appointments; that those two classes when disqualified, should receive two-thirds of their present emoluments, one-half thereof to be paid out of the union rates, the other half out of the Consolidated funds, or from a source which without prejudice to any interests might be made available to this small extent, viz., the surplus funds of the disestablished Irish Church.

I should observe, that notwithstanding the hard knocks given occasionally to dispensary committees and boards of guardians, for their want of consideration for medical officers, cases occasionally arise in which, from motives of kindness towards those gentlemen, an amount of clemency is awarded them in their old age and infirmity, at the expense in the way of suffering to the sick poor. A short Act of Parliament embodying those views might get due consideration even at the present time.

I am, &c.,

A POOR-LAW MEDICAL OFFICER.

May 6, 1878.

NAVAL MEDICAL SERVICE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Seeing that the Medical Department of the Navy are making a spasmodic effort to fill up the blanks in the list of surgeons—blanks caused by the ill-treatment of the Service at the hands of the naval authorities—I beg leave to recommend those gentlemen who may be induced to trust the known *mali fides* at the head of affairs, first to learn all the duties of a naval footman or valet, so as to be able to dance attendance on the executive officers generally, the captain particularly, as in no other way will he have a chance of success, or even of a comfortable existence. As far as the regulations are concerned, they are all very well to read, and look nice, but I do not believe the surgeon need fear that they will in any way be used in his favour, should doing so clash with the humour or convenience of even a sub-lieutenant.

A class-fellow of my own some ten years ago presented himself for examination at Burlington House, passed, getting first place for his pains. The regulation stated that the gentleman who passed so should get his promotion in five years. My friend did not, and in disgust threw up the whole concern. Such Russianisms as these are not calculated to make the Service agreeable to men of spirit or culture, to say nothing about professional ability.

I am, &c.,

A CIVILIAN.

THE INFLUENCE OF GREEN TEA AS AN ANTIDOTE TO POISONING BY OPIUM.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Mr. Tufnell was kind enough to forward me a copy of your journal of the 3rd inst., containing a report of the discussion which took place before the Surgical Society of Ireland on a short paper read for me by Mr. Tufnell, setting forth the valuable effect of tea or theine as an antidote to poisoning by opium.

I do not think Dr. Kennedy's criticism altogether fair. He sets out by expressing a doubt as to the accuracy of my statement as to the quantity of opium taken; but I not only had the evidence of the servants, who knew what was in the phial when the lady commenced taking the drug, and what was in it when she was seized with a convulsion, but I had also the evidence of the lady herself after her recovery, who assured me she had taken two teaspoonfuls of Battley every half hour, from 4 o'clock p.m. to 11 o'clock p.m. the same evening. This would give us the exact quantity swallowed, say twenty-eight drachms, or three ounces and a half. *Here then is a fact.* Again, Dr. Kennedy says neither an emetic nor the stomach pump were used to clean out the stomach. What emetic, I would ask, would be likely to have acted on a stomach in the paralysed condition we may reasonably suppose this one was, which had been acted upon for seven hours by the large quantity of opium above mentioned? Besides, what probable benefit would have been obtained by an emetic when a very large portion of the drug taken must have been already absorbed, and was now doing its deadly work? With regard to the stomach pump, I would remark that when I saw my patient I thought she was dying; the cold extremities, the contracted pupils, the drawn and hippocratic face, the absence of all pulse, and the very slow respiration, all indicated this event as imminent. There was no time to be lost, and as a *pis aller* I administered the tea by enema. I had no pump at hand, and it would have taken too long to send to a distance for one; besides which, I believe, in her extremely low condition, the introduction of the tube would have extinguished the flame of life now flickering so feebly in the socket.

Dr. Kennedy next takes exception to the rapid recovery in the case reported, and says, "it had been his lot to see several cases of poisoning by opium, and even when they *did* recover, the recovery occupied a very much longer time than that recorded in the case now under notice." I thank Dr. Kennedy for this admission, for in it he offers the highest possible testimony to the efficacy of tea in these cases, as I presume he treated his own cases in the ordinary way.

I have said nothing against belladonna, or other antidotes to opium. I have advanced no theory. I have merely used the remedy which was first suggested to my mind by reading a clinical lecture given by your late eminent and lamented townsman, Dr. Graves, in which he recommends tea as an expergefacient in the coma of typhus; and having used the same remedy largely in poisoning by alcohol, and in other morbid affections of the blood, with wonderful effect, I feel I should be wanting in my duty not to make my experience known to the profession, even at the risk of "mystifying" some of my professional brethren on the other side of the water.

My thanks are due to Drs. E. H. Bennett and Bigger for their friendly remarks with reference to the case of poisoning by opium mentioned by the latter gentleman, which recovered after a large use of coffee—which also contains theine. I take it, the recovery would have been more rapid had the remedy been given by enema, as I believe that in all these cases of poisoning by opium the stomach is not in a fit condition to absorb the remedy at all, and certainly not so rapidly as the rectum.

By inserting this communication in an early number of your valuable journal, you will very much oblige,

Yours faithfully,

JAMES A. SEWELL, M.D.

Quebec, April 25.

THE PURIFICATION OF WATER.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Having read in your paper of the 1st inst. an annotation on the purification of water, referring to a lecture by Prof. Bischoff, in which you describe him as inventor of the most perfect filter extant, I venture to suggest that this is only the Professor's *own idea*. Had you been present at the meeting at the Society of Arts you would have heard a very different opinion expressed, amongst others by Mr. Spencer, who has devoted a long life to the purification of water through various preparations of iron. If Prof. Bischoff were content only to blow his own trumpet no one could complain, but he must needs abuse animal charcoal, knowing that unless he can create a scare in the use of that material his spongy iron would soon go the way of all similar preparations for water-purifying processes. Now, as regards his statement that for filtering Thames water you must change the animal charcoal every three months, I have no hesitation in saying it is a gross misstatement, because in alluding to Thames water he does not mean water actually taken from the river, but as supplied by those companies who derive their supply thence, and we have found, after an experience of fourteen years, that filters filled with properly prepared animal charcoal will last on an average two years, and, in confirmation of this, I need only refer to Prof. Bischoff's great supporter, viz., Professor Frankland, who, in a series of reports to the Registrar-General, extending from 1856 to 1870, gives the results of his experiments with animal charcoal, and as animal charcoal has not changed its constituents since that date, one is at a loss to understand how what was looked upon as perfect then should so wonderfully have changed its character on the advent of spongy iron. The profession and the public may also not be aware that animal charcoal is at least three times more expensive than any preparation of iron; hence, as this very spongy iron was submitted to us (as also have numerous other preparations been) with the view of our adopting it, I need scarcely say that had we found it a suitable material for water filtration we would gladly have adopted it, if only as a matter of economy, although at the same time if even a more costly material than animal charcoal were presented to our notice it would equally receive our attention, our endeavour being to produce the best method of filtration, regardless of expense. Hitherto, we have found nothing superior to that material, and as regards all these iron preparations, the merest tyro in chemistry can easily ascertain that they render the water passing through them unfit for all ordinary dietetic purposes by their imparting to it a chalybeate character, which, however beneficial under medical advice, is certainly not otherwise to be made an article of universal consumption, especially for infants and young children.

I remain, Sir, your obedient servant,

R. RUDING,
Secretary, London and General Water Purifying Company, Limited.

THE ANNUAL MEETING OF THE IRISH MEDICAL ASSOCIATION.

THE yearly assembly of the Association will take place on Monday, the 3rd of June, and the programme of the subjects to be discussed at it is of unusual interest and importance. The report of the Council will in itself present the members with matter for consideration in connection with almost every detail of special interest to the profession in Ireland at this moment. The labours of the Council on behalf of the profession, and especially on behalf of Irish poor-law medical officers, have been untiring and comprehensive, and it will be a matter of personal interest to every member of the Association to hear what has been done during the past year. Dr. Robert MacDonnell, the outgoing President of the Royal College of Surgeons, will be recommended by the Council to occupy the Presidential Chair of the Association.

The members will, as is usual, meet at breakfast at the Shelburne Hotel, and will proceed to transaction of business, at 12 o'clock, at the College of Surgeons. The Royal Medical Benevolent Fund Society will meet at the College of Physicians at 4 o'clock, and the annual dinner of the Association will be held at the College of Surgeons at 7 p.m. We trust that the provincial members of the Association will, even at some inconvenience, arrange to be present at the meeting. The Council has all the right which good service gives it, to expect the presence and encouragement of the members, and nothing would so greatly dishearten them in their efforts as a meagrely attended Annual Congress.

THE APPROACHING ELECTION OF COUNCIL AT THE IRISH COLLEGE OF SURGEONS.

THE last Monday in May, and the first Monday in June would be red-letter dates in the College Calendar (if it had one), and their approach is the cause of some interest in medical circles in Dublin. On the 27th of May the Fellows of the College will meet to receive the Annual Report of Council, and it is not improbable at the present critical period of medico-educational affairs, that some animated discussion may take place. At the meeting of the College on the 3rd of June, the Council and officers will be elected. In consequence of the transference of Dr. Wheeler to the Court of Examiners, and the resignation of Mr. Butcher, two new Councillors must necessarily be chosen. For the honour of a seat on the Council, Mr. Croly, Senior Surgeon to the City of Dublin Hospital; Dr. Jacob; Dr. Thornley Stoker, of the Richmond Hospital; Dr. Roe, and Dr. Madden are already declared candidates. Mr. Smyly will be the new President, and the Vice-chair will, in all probability, be occupied by Dr. Mapother, Professor of Physiology in the College.

The Hospital for Sick Children.—The twenty-sixth annual meeting of the governors of this hospital in Great Ormond Street, London, was held on Thursday last, Lord Kinnaird in the chair. The annual report and treasurer's accounts were submitted and adopted by the meeting. The hospital contains 104 beds in the five larger wards, besides 16 beds in the isolated wing, and 8 beds in smaller separate wards. The total number of children admitted to the hospital last year was 927, a larger number than in any previous year; the out-patients admitted were 9,800; the number of children sent to the Convalescent Hospital, Highgate, where 52 beds are provided, was 396. From various causes the income of the hospital had suffered diminution, the amount received being £9,634, while the expenditure amounted to £9,994, leaving a deficit of more than £300. The amount paid on account of the new building was £4,700, which entirely absorbed the building fund, and left a considerable amount to be raised to meet the outstanding account. The committee desired to correct the erroneous impression that the hospital is a wealthy institution; they drew attention to the balance-sheet to show that this is not so, and that the want of funds compels them to keep some of the rooms empty, and may lead to the reducing of the present number of inmates.

NOTICES TO CORRESPONDENTS.

☞ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

THE INNER LIFE AND ECONOMY OF A LOCK HOSPITAL IN INDIA.

WE have much pleasure in announcing a short series of papers on this—at the present time—interesting subject from the pen of Surgeon-Major W. Curran, of the Army Medical Department, who has been in India for the past seventeen years, and is now in medical charge of the Government Lock Hospital at Sitapur. We hope to commence these papers the first week in June, and beside the interest which would naturally attach to a peep into the interior of a hospital in that distant portion of the British Empire, many interesting facts will be brought to light on the subject of the Contagious Diseases Act, about which our columns have, from time to time, been the medium of discussion.

MR. S. MESSENGER BRADLEY'S clinical lecture "On Contractures" will appear in an early number.

DR. H. M. HAMBLIN, Lima, Illinois, is thanked for his kind offices.

DR. WOAKES will lecture "On Throat and Ear Complications" at the Hospital for Diseases of the Throat to-day and the two following Wednesdays. Members of the profession and medical students admitted free.

THE MORGAN ANNUITY FUND.—Notice is given in our advertising columns of a proposal to be submitted at the annual meeting of the Royal Medical Benevolent College on the 30th, to make an additional bye-law relative to this Fund, to which the attention of subscribers is directed.

DR. BOURNEVILLE, Paris.—The work of Monsieur Duret has not yet come to hand.

"PROFESSIONAL ADVERTISING."

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—I quite disapprove of the notices of lectures to medical students appearing in the daily newspapers. For the notices of my own Introductory *Address* (which was presided over by Wm. MacEwen, Esq.) that appeared in these newspapers on the 10th inst. I am not at all reponsible, nor did I in any way influence or "inspire" the writers of them.

Yours truly,

JAS. PATTERSON CASSELLS, M.D.

[*** We are glad to receive this disavowal from Dr. Cassells as it confirms the opinion we expressed in our last issue, that we did not believe he had any knowledge of the circumstance, or would sanction the reproduction in a lay newspaper of his lectures to medical students. —ED. M. P. & C.]

ACTION FOR SLANDER BY A PHYSICIAN.—A physician in Canada recently brought an action for slander against a chemist, obtaining damages and costs. The libel consisted in the chemist openly stating that a patient of the doctor's would not have died but for improper treatment. An apology and retractation was asked and refused, and an action ensued with the before-mentioned result. It would serve a useful lesson if slanderous tongues about members of the profession in this country were taught that they could not injure a man's reputation with impunity.

QUEKETT MICROSCOPICAL CLUB.—On Friday, at 8 p.m., Mr. B. Thompson Lowne, "On the Structure of the Eyes of Insects."

CLINICAL SOCIETY OF LONDON.—On Friday, at 8½ p.m., the President (for Dr. Day): "Sequel of a Case of Chylous Discharge from the Leg." Dr. Farquharson, "On a Case of Quinine Rash." Mr. Cripps, "On a Case of Gastrotomy for Intestinal Obstruction." Dr. Murchison, "Incubation Period of Scarlet Fever and of some other Diseases." Mr. Bryant, "Sudden Death following Tapping of and Hydatid of the Liver." Mr. Brown, "Sequel of a Case of Cancer of the Tongue."

A MEDICAL OPINION.—An American medical contemporary gives the following as a true copy of a written opinion given by one who has an extensive practice: "Mr. ——, you have a lamnis of the Lung, turbit Lever, sower Stomak, and muskle affection of the Left Arm and right Hipp. I will help you conserable, but it is not a perfect cure for you.

DR. O. F.—Such conduct on the part of a costermonger would be highly reprehensible, still more so on the part of a medical man. It is not, however, of such a nature as would justify its exposition in our columns. 'Tis sufficiently painful to read in the police news of a penny newspaper.

M.D.—"Murchison on the Liver."

VACANCIES.

Ayr Hospital.—House Surgeon. Salary, £50, with board. Applications, with testimonials, &c., to the Town Chamberlain, Ayr, N.B.

Brighton Hospital for Sick Children.—House Surgeon. Salary commencing at £50, with board. Applications, with testimonials, to the Chairman.

North Dublin Union, Rathfaraham and Whitechurch Dispensary.—Medical Officer. Salary, £125. Election, June 3.

Northampton County Lunatic Asylum.—Medical Superintendent. Salary, £500, with residence, &c. Applications before the 27th inst. to the Clerk of the Peace, County Hall, Northampton.

Wrexham Infirmary.—House Surgeon. Salary, £100. Applications to J. Oswell Bury, Temple Row, Wrexham.

APPOINTMENTS.

APPLEYARD, J., M.B., F.R.C.S.E., an Assistant Surgeon to the Eye and Ear Hospital, Bradford, Yorkshire.

BEVERLEY, W. H., L.R.C.P.L., M.R.C.S.E., Resident Medical Officer to the Worksop Dispensary.

DRUMMOND, D., M.D., a Physician to the Newcastle-upon-Tyne Infirmary.

FORBES, D., M.B., House Surgeon to the Bootle Hospital.

GRAHAM, C. R., M.R.C.S.E., Junior House Surgeon to the Royal Berkshire Hospital, Reading.

HUME, G. H., M.D., L.R.C.S.Ed., a Surgeon to the Newcastle-upon-Tyne Infirmary.

JOHNSTON, R. C., M.B., C.M., a House Surgeon to the Edinburgh Royal Maternity Hospital.

MACKAY, W. B., L.R.C.S.I., L.K.Q.C.P.I., Medical Officer, &c., for the Glencullen Division of the Dundrum and Glencullen Dispensary District, Rathdown Union.

MARSH, W. J., M.R.C.S.E., House Surgeon to the Royal Cornwall Infirmary, Truro.

O'CONNOR, P., M.D., C.M., an Assistant House Surgeon to the South Dispensary, Liverpool.

SAUL, W. W., M.D., Hon. Medical Officer to the Lancaster Infirmary.

TURNER, R. S., M.D., L.R.C.S.Ed., Medical Officer for the Parish of Keith, Banffshire.

Births.

DALY.—May 13, at Kingston Bagpuize, Abingdon, the wife of J. H. Daly, L.R.C.S.I., L.R.C.P. Lond., of a daughter.

JARDINE.—May 12th, at Stanwix, Lancashire, the wife of Major Jardine, M.D., A.M.D., of a son.

ROWLAND.—May 18, at Gloucester House, Malvern Wells, the wife of H. Mortimer Rowland, M.D., of a son.

Marriages.

BUCKELL—GRIFFIN.—May 15, at Ledbury Parish Church, Dr. J. William Buckell, of Ledbury, to Dora, second daughter, of William Griffin, Surgeon, of Ledbury.

SHAPLEY—OVERELL.—May 16th, at the Parish Church, Leamington, H. T. Shapley, M.B., M.R.C.S., to Eugenie Eliza, daughter of William Overell, Solicitor, of Leamington.

Deaths.

BERNARD.—On the 6th May, at Clifton, James Fogo Bernard, M.D., aged 71.

BYRNE.—On April 18th, at Kilsallaghan, co. Dublin, William Charles Byrne, L.R.C.S.I., aged 68.

COXE.—On May 9th, at Folkestone, Sir James Coxe, M.D., a Commissioner in Lunacy for Scotland, aged 67.

ELKINGTON.—On May 16th, at Alcombe, Somersetshire, Francis Elkington, M.D., late of Birmingham, aged 77.

LESLIE.—On May 5th, at Hampstead, William Alexander Leslie, M.R.C.S.E., Surgeon-Major, Madras Army, aged 58.

MCCOWAN.—On May 7th, at Paisley, Robert Thomas McCowan, M.D.

MEADOWS.—On May 8th, at Victoria Street, Westminster, Henry Mello Mollerus Meadows, L.R.C.P.Ed., aged 70.

SANDYS.—May 15th, at Eversholt House, Bedford, Samuel Sandys, M.R.C.S., late of Kentish Town, London, aged 67.

WHITE.—On May 2nd, at Park Road, Southport, William White, M.D., aged 71.

IRISH POOR-LAW INTELLIGENCE.

VISITING PHYSICIANS TO IRISH DISTRICT ASYLUMS.

THE following very important letter has been addressed by the Council of the Irish Medical Association to the Chairman of the Irish Lunacy and Poor-law Inquiry Commission. It deals, as our readers will observe, with a subject to which we have very frequently called attention, and its facts and arguments are, in all respects, worthy of attention.

Irish Medical Association,
Royal College of Surgeons in Ireland.

To the Chairman of the Poor-law
and Lunacy Inquiry Commission.

SIR,—The Council of the Irish Medical Association has learned that your Commission has instituted inquiries whether—

"With a view to efficient administration in the asylum, and to affording protection against improper treatment or detention of inmates, the present system of visiting and inspection can be improved, or any change or modification in the existing rules can be made with advantage,"

And it is understood that, in response to this inquiry, it has been suggested to your Commission that an Assistant to the Resident Medical Superintendent should be appointed in all asylums, and that the duties of Visiting Physicians should be more accurately defined than they are under the existing rules. The questions respecting the duties, powers, and responsibilities of Visiting Physicians which are raised by this inquiry, are, in the opinion of this Council, of great import to the efficiency of the lunacy system in Ireland, especially considering how vitally essential it is to maintain in full force an independent and extraneous supervision of asylums; the Council therefore feels it necessary to call the attention of your Commission to the effect of past legislation in weakening that control from without which it was the object of former regulations to preserve.

The Commissioners are, no doubt, aware that under the first code of rules for the management of asylums, promulgated in 1843, the Manager was not necessarily a medical practitioner. In 1862 it was made essential that he should be a fully-qualified medical man, and he was entitled Resident Medical Superintendent. In 1870 the rules for management of asylums were revised, and again in 1874. The Council begs to direct the attention of the Commission to the alterations of phraseology of the rules at these periods, and desires to point out that the tendency, if not the purpose, of those alterations, and of the methods of asylum administration founded thereupon, has been steadily and surely to divest the Visiting Physician and the Board of Governors of that controlling and supervising power which they had previously possessed, and to concentrate in the Resident Medical Superintendent the highest and largest authority, for the exercise of which he is, practically, responsible only to the central department at Dublin Castle.

In illustration of this statement the Council begs to refer to the consecutive alterations of rule.

Firstly, as regards the duties and authority of the Visiting Physician.

a. His Title.—By Rules of 1843 he was entitled "The Physician." By those of 1862, "The Consulting and Visiting Physician," his functions being thus—by inference—restricted to occasions when he is "consulted," or asked his opinion.

b. Times of Visiting.—By 1843 Rule (42) he was to visit not later than two o'clock. To "frequently go round the asylum so as to see the state and condition of every inmate (Rule 47). To attend the board and afford advice to the Governors, and to report regularly to them" (Rule 51). And lastly, "to visit the institution whenever he thinks proper, and his additional and irregular visits should be encouraged."

By 1862 Rules he may visit *only* within three hours out of the twenty-four. He must *not* go round the house except after communicating with the Resident Medical Superintendent, in company with whom he shall visit all labouring under bodily disease (Rule 32). He is *not* empowered to attend the board. He is *not* authorised to report to them, and he is *not* entitled to visit the asylum at any time outside his regular hour, except when called upon by the Resident Medical Superintendent.

c. His Professional Functions.—By 1843 Rules he was to "*prescribe* for all such patients, servants, and officers as may require assistance."

By 1862 Rules he was to "visit *all* patients labouring under *bodily* disease, whose course of treatment he shall direct (Rule 32), the Resident Medical Superintendent being at the same time "entrusted with the *moral and general* medical treatment" (Rule 19). The Visiting Physician was also to be consulted "in complicated or difficult cases of *mental* disease, or any case requiring particular treatment."

By 1870 Rules he is no longer authorised to "*direct* the course of treatment," even in cases of purely bodily disease (Rule 41).

It will thus be obvious to the Commissioners that by these alterations of rule, the Visiting Physician is divested of much of his authority in respect of the treatment of sick lunatics, and the Council is aware that the rules have been construed in many asylums, as precluding the Visiting Physician from taking official notice of inmates suffering from severe bodily illness unless when required by the Resident Medical Superintent to do so.

The Council submit to the consideration of the Commissioners the question whether it is desirable that the medical care of lunatics in serious, possibly fatal, disease should be confided to the Resident Medical Superinten-

dent with a purely discretionary power to seek other advice. It is deserving of consideration, in relation to this question, that the Resident Medical Superintendent is, according to the practice recently adopted, usually a gentleman who has served some time as assistant in a district asylum, to which he was probably appointed shortly after he had received his medical qualification. He has thus been promoted to the office of Resident Medical Superintendent in consequence of his acquaintance with mental diseases, yet possessing only a limited experience in the treatment of bodily disease. Even in exceptional instances, in which a physician of experience in practice may be selected for the office of Resident Superintendent, it is obvious that—his whole time being occupied by the management of a great institution, and with the mental and moral treatment of several hundreds of lunatics, it is not reasonably to be expected that he will long continue to be fully capable of treating obscure or dangerous diseases according to the most approved methods. The Council is, therefore, of opinion that the treatment of inmates suffering from bodily disease, and the management of epidemics within the institution, ought, in all cases, to be confided to the Visiting Physician, and that it should be declared to be the duty of the Resident Medical Superintendent to report such cases to the Visiting Physician on their occurrence.

Of far higher public importance, however, is the hindrance which the alterations of rule referred to above interpose against the supervision of the asylum by the only officer who is unconnected with its internal management, and against his communicating freely to the Governors such facts as may come to his knowledge, or his opinions respecting details of the management of the institution. It is hardly necessary for the Council to point out—respecting the visitation of the asylum by an officer whose duties are under the complete control of the Resident Medical Superintendent (Rule 23, 1862)—who is only permitted to visit at a stated hour—who is not allowed to see the patients except in presence of the Resident Medical Superintendent—who is not authorised to interfere in respect to their mental condition, except with permission of the Resident Medical Superintendent, and in case the patient is under restraint —who is doubtful as to his right to notice even their bodily condition unless "consulted" by the Resident Medical Superintendent—and who is not permitted to state his views to his Board of Governors either personally or by report— that such a visitation can be of little value either as a safeguard for the inmates, or as a check upon possible abuses within the asylum.

While emphatically deprecating any intention to detract from either the administrative or professional repute of the Resident Medical Superintendent of Districts Aylums in Ireland, the Council cannot hesitate to express their decided opinion that the fullest opportunity ought to be afforded for external supervision of every asylum in which lunatics are confined, and for observation of the condition and progress of its inmates by persons outside its walls, and not concerned in its administration; and that, with this purpose, the Visiting Physician — the only continuous link between the lunatic within the asylum and the world without—ought to be restored to a position of independence in the discharge of his duties; and the Council dissents from the policy of administration of a lunatic asylum by the hands of any one officer, that officer being responsible almost solely to the central department, which cannot be fully aware of the day-to-day working of the institution.

That policy has for very many years been steadily developed by the central department by means of the gradual alteration of rules to which the Council has referred, by discouraging the interference of Boards of Governors and Visiting Physicians in the management of asylums, and by passively recognising the limited responsibility of Resident Medical Superintendents to their Boards of Governors; and the Council, therefore, fearing that the total abolition of the office of visiting physician may be contemplated, and being interested for the maintenance of the public confidence in the administration of Irish lunatic asylums, feels it its duty to submit these facts and opinions to the attention of your Commission.

I am, Sir,

Yours very faithfully,

JOHN WILLIAM MOORE, M.D.,
Secretary of Council, I. M. A.

THE KILMALLOCK INSURANCE FRAUDS.

IT will be in the recollection of our readers that in the year 1874 Drs Meehan and Sheedy, of Kilmallock, were indicted for having conspired with the local agent of the New York Insurance Company to defraud that company, they having given certificates of examination and approval to persons whom they had never examined at all. They were convicted and sentenced to twelve months' imprisonment, and underwent that penalty. On their discharge from prison an application was made to the General Medical Council to replace on the Register their names, which had been removed, and the Council—believing that they had acted as they had done upon the persuasion of the local agent, and on his assurance that the examination of the persons insured had been dispensed with by the Directors of the Company, and considering that their acts, however reprehensible and imprudent, did not amount to intentional fraud—consented to reinstate them. At a recent meeting the Limerick Board of Guardians elected Dr. Meehan the visiting medical officer to the house, in room of Dr. F. W. O'Connor, resigned, and at the following board a letter was read from the Local Government Board relotive to the appointment. The Local Government Board wrote that they had before them the answers to the usual questions as to Dr. Meehan's medical and other qualifications for the office. In answer to one of those questions it is stated that Dr. Meehan was some time medical officer of Bruff Dispensary district, in the Kilmallock Union, which office he ceased to hold on July 17, 1874. It was probably the restoration of Dr. Meehan's name to the Medical Register which led to Dr. Meehan's appointment by a large majority of the guardians present at the election, but the Local Government Board do not consider this proceeding to be justifiable on that ground. It must be borne in mind that by this act of the Medical Council Dr. Meehan was merely enabled to pursue his practice as a qualified medical man, and it was for those who choose to place so much confidence in him as to seek his services as their medical adviser to use their discretion in doing so, but this is a totally different matter from the board of guardians and the Local Government Board appointing or permitting Dr. Meehan to have charge of so many hundred of patients daily, who have no voice in choosing their medical attendant, and who might most reasonably be supposed to place no confidence in Dr. Meehan. The Local Government Board must, at the same time, remind the guardians that, by the 22nd section of 6th and 7th Vic., cap. 90, no person convicted of fraud is qualified to act as a guardian of the poor, and that such an objection seems to apply with peculiar force to paid officers of high position and trust in the workhouse, and the disqualification would probably have been extended to thos officers if it had been thought likely or even possible they would be appointed. The Local Government Board, therefore, decline to approve Dr. Meehan's appointment, and request the guardians to proceed to a new election by advertisement in the usual manner.

Mr. Michael Meehan, as brother to Dr. Meehan, said he hoped the board would allow him to explain that his brother had been convicted by a packed jury, from which some of the most respectable men were excluded.

Mr. Meehan continued that his brother's conviction was to be made the subject of inquiry that night in the

House of Commons, and under the circumstances he would ask the board to defer the consideration of the Local Government Board's letter until the result was known. His brother, he repeated, was convicted by a packed jury. Why, the fact was that he (Mr. Meehan) was also convicted by the grand jury of the county of Limerick, but he was let out of it, and why? because there was no case or a particle of a case against him.

Alderman Clery thought it very arbitrary of the Local Government Board to take the action they did after Dr. Meehan's name had been reinstated on the medical registry by the Medical Council.

Lord Clarina—This is not the place to appeal about packed juries.

The following proposition was moved :—

"That the consideration of the report of the Local Government Board in the case of Dr. Meehan be postponed for one month, pending the inquiry which we understand is to be instituted into his case in the House of Commons, and that Dr. Meehan be continued in the present employment of the board of guardians until we hear the decision of that enquiry, as this board has already shown in their selection of Dr. Meehan that they believe in his ability: and we request the Local Government Board to sanction Dr. Meehan's continuation in office for one month from this date."

Lord Clarina—I feel it my duty to propose that we proceed to carry out the instructions contained in the letter from the Local Government Board. I agree with every word they have said as to their objections to the appointment, and I think they are thoroughly sound.

Ultimately a poll was taken, when the resolution was carried by a large majority, only two guardians dissenting.

WATERFORD UNION.

CONJOINT EXAMINATION.

THE Clerk said he had received the petition upon this subject from the Limerick guardians.

Mr. Conn—That only touches the profession, and the profession are very well able to take care of themselves.

Dr. Scott said it deeply concerned the poor, as at present persons were able to get diplomas from one or other of the examining bodies who were unable to treat the very simplest case of illness. Surely, it was the interest of the guardians that medical men entering their service should be qualified and able to attend the poor properly.

Mr. Bloomfield said an Act of the kind was very badly wanted in the interest of the poor. The rich can go to any doctor they chose, but the poor had no choice, and should go to the one, no matter whether he was good, bad, or indifferent, and he might be either of the two last, owing to the lowness of the standard of education of the place where he got his diploma, whereas if the prayer of the petition was granted, they would get a much better class of medical men for their dispensaries. He moved the adoption of the petition.

Ald. Redmond seconded the motion.

Captain Power opposed the motion. The more examining bodies they had the better men they would get.

The motion was then put and carried, the voting being—for, 10; against, 9.

MONAGHAN GUARDIANS.

THE PRESS AND POOR-LAW.

THE guardians of the Monaghan Union adopted recently a resolution excluding the representative of the *Advocate*—a local paper—from their meetings, on the ground that it "misrepresented" the acts of the guardians. Thereupon the proprietor appealed to the Local Government Board, who replied as follows :—

Dublin, 8th May, 1878.

The Local Government Board for Ireland acknowledge the receipt of your letter of the 2nd inst., referring to the proceedings of the Monaghan Board of Guardians of Monaghan Union, at their meeting on the 1st inst., when it appears a resolution was adopted excluding the reporters of the *People's Advocate* newspaper; and in reply the Local Government Board desire to state that it is entirely within the discretion of the guardians, whether they will admit any, and if so, what person to be present in the board-room during their meetings.

By order of the Board,

B. BANKS, Sec.

It does not seem to us at all evident that boards of guardians should be permitted any such right as the restriction of the publicity of their proceedings, or should be allowed to make admission to their meetings contingent on praise of themselves and their acts. We are satisfied that it is directly essential to the effectual administration of the Poor-law Service that the public should know all about it, and should be encouraged to criticise the acts and opinions of its administrators; and we, therefore, hold the view that if it be, as stated by the Local Government Board, "entirely within the discretion of the guardians whether they will admit any, and if so, what person to be present," the sooner the guardians are deprived of the exercise of such discretion the better for the taxpayers and the pauper population. It is fortunate, however, that no attempt of guardians to muzzle the press can ever produce any considerable effect in furtherance of that object and must usually have the result of increasing the severity of newspaper criticism. It can hardly be expected by the Monaghan guardians that the editor of the *Advocate* will find any difficulty in ascertaining with minuteness all that goes on in their board-room, or that their attempt to intimidate him will cause him to refrain from expressing the views of his journal upon their conduct. If the proprietor of a newspaper outsteps the proper limits of criticism those aggrieved have their remedy at law (and a much more ready remedy than that afforded in other suits); but they need not hope that they can make editors obsequious or subservient by any such means as those which the Monaghan guardians have used.

THE ABBEYLEIX GUARDIANS.

THE APOTHECARYSHIP.

THE following correspondence was read :—

"Local Government Board, Dublin,
11th May, 1878.

"SIR,—With reference to a minute of the board of guardians of Abbeyleix Union of the 30th ult., relating to the appointment of Dr. Stoney to perform the duties of apothecary to the workhouse, I am directed by the Local Government Board for Ireland to forward herewith for the information and consideration of the guardians, a copy of a letter which they have received from Mr. Thomas Fleming, P.L.G., on the subject. I am at the same time to state that the Local Government Board are not aware that any authority exists which would entitle a medical gentleman to compound the prescriptions of another practitioner, except he was a licensed apothecary, or a pharmaceutical chemist.

"By order,

"B. BANKS."

The Chairman asked the clerk if they were to consider the appointment vacant by the letter that had been read from the Local Government Board.

Clerk—I think so.

Mr. Talbot—On this day fortnight there was a letter read from the Local Government Board suggesting that

Dr. Swan should compound the medicines, as is done in all the unions about. It would be a great saving of expense to the union, and I am now going to propose a resolution which I trust will meet the guardians' acceptance, namely: "That Dr. Swan, medical officer of this house, be requested to continue to compound the medicines used for the patients in the infirmary and hospital, as is done in other unions in this neighbourhood of a similar size, and that the additional payment for same be left to the Local Government Board."

Mr. Caldbeck would rather give £50 a year to support an apothecary in the town than a lesser sum to a doctor.

Clerk—You cannot appoint Mrs. M'Loughlin. You must give the appointment to her assistant if you give it to any.

Mr. Leech anticipated great difficulties from such an arrangement.

Mr. Foster—The neighbourhood is crying out for an apothecary as usual, and as we are about to pay a salary we may as well advertise. I move that we advertise for an apothecary.

Mr. Owen explained that the object in view in Dr. Stoney's appointment was to do away with the office of apothecary, so that when a vacancy would eventually occur in the house, they would be in a position to appoint a doctor who would compound his own medicines.

Captain Bland thought the appointment of Dr. Stoney a very good one. He looked upon the Local Government Board's letter as indecisive and unsatisfactory.

Mr. Owen said if Dr. Stoney was not competent to compound the medicines it would be a different thing.

Dr. Swan was here called into the room. In reply to the chairman, he said Dr. Stoney was fully competent to compound medicines, but by the rules of the Apothecaries' Hall he could be prosecuted if he compounded any one else's prescriptions, and be fined for it.

Mr. Owen—As your assistant, as assistant to the house, would not that cover him from prosecution?

Dr. Swan—He could not be prosecuted for compounding his own prescriptions, but he lays himself open when he compounds mine, and is paid for it.

Clerk—Dr. Stoney was not appointed as apothecary but as assistant.

Mr. Foster—He was appointed for a specific purpose, that was to compound the medicines; and, according to Dr. Swan's statement, he is liable to a penalty for so doing, inasmuch as he receives payment for it, so that I do think he is out of court altogether.

Chairman (to Dr Swan)—In your opinion, do you think Dr. Stoney would be subject to a prosecution?

Dr. Swan—I think so, if anyone chose to prosecute.

Captain Bland proposed as an amendment, "That the question be submitted to the Local Government Board for reconsideration, and that the clerk write to them and explain to them more fully the advantages and economy of the appointment."—Passed unanimously.

RATHDOWN GUARDIANS.

BURIAL OF SMALL-POX PATIENTS.

THE Chairman said he wished to call the attention of the board to the matter of interment of persons dying of small-pox. A young man admitted to the house had recently died, and while a patient he had been attended by one of the pauper inmates. The man was coffined by this pauper, who watched over him, and the body was allowed to remain 36 hours without being interred. The pauper had taken the disease, and, sad to relate, had also died. It appeared to him (the chairman) that it was absolutely necessary to have the parties dying of infectious disease interred at once. He considered they should apply to the Local Government Board for power to inter those persons with as short delay as possible. Mr. Rafferty considered that if the persons were coffined, sent to the dead house, and allowed to remain there for twelve hours, it would be quite long enough, after the parties' friends had got notice, and when they might attend for the purpose of identification. It was then decided to apply to the Local Government Board for the power to make the interment at the earliest possible moment.

ALCOHOLIC DRINKS: AS MEDICINES, AND AS POISONS. (*a*)

By ALFRED CARPENTER, M.D. Lond., M.B., J.P., President of the Croydon Microscopical Society, Lecturer on State Medicine, St. Thomas's Hospital, &c.

(*Continued from page* 421.)

The principle upon which we propose to cure the habitual drunkard is to restrain him from the use of his liquor, so that he may entirely recover his health and his power of self-control. There are several stages in this process. First, his digestive power has to be restored, a very difficult and a very slow process. Then the deposits which have already taken place in his glandular system, his blood vessels, and nerve centres have to be removed, and altered membrane has to be restored. Simple food with healthy habits of body reduce the alcoholic saturation to a minimum, and enable the patient to get healthy digestive power.

The dyspeptic state must be cured before the alterations in glandular organs can be removed; they must do their duty properly before the nerve tissue can be renovated, and until the whole are restored, any return to alcoholic diet is followed by relapse. It is only by long-continued self-denial that cure can be effected. That I have not overdrawn the picture as to the condition of the nervous system and the seat of disease in such cases, is shown very fully by Dr. Magnan in his work on Alcoholism, which has been translated by Dr. Greenfield. It abounds with instances which prove most clearly that the immediate action of alcohol is to dilate the capillaries of the nerve centres, increasing them to three or four times their ordinary dimensions, and thus paving the way for that atrophic degeneration which is frequently associated with other changes in advanced states of alcoholism. The cases detailed by Dr. Magnan are very instructive, and if taken in conjunction with others, in which, with similar symptoms, the microscope reveals changes which were formerly unsuspected, we cannot doubt at all as to cause and effect.

The hallucinations and delusions, which accompany excess of alcohol even in young beginners, are associated with capillary dilatation, and, as a sequence, there is a pressure on nerve substance which cannot be repeatedly renewed without the risk of subsequent atrophy or degeneration of one part or another of the tissue immediately affected.

Is it to be wondered at that cure in such cases is only to be obtained by long-continued treatment? Is it a fair objection to take to long-continued treatment that relapses are common? Can relapse be considered a reason for not attempting cure, and is it to be endured that, with a knowledge of the capability of cure, we should not have power given to us to attempt it, because the disease is said to be the result of a vicious habit?

What would be thought of our profession if we declined ta cure syphilis when our help was sought by those infected? We ought to have the power given to us to cure the habitual drunkard, especially in those case in which the victim himself, conscious of his own weakness, implores us to take charge of him, and keep him from that which is certain to lead him on to hopeless ruin.

An opinion was expressed to the Lords' Committee on Intemperance that dipsomania is a kind of epilepsy, and that its attacks correspond with the latter disease. I cannot think that there is any foundation for this idea any more than that attacks of asthma or any other recurring disease may be epileptic. That dipsomaniacs often become epileptic is undoubtedly true; but many forms of disease tend to set up epileptiform attacks before a fatal termination arises. Epilepsy will arise in any kind of constitution, but drink craving will only be induced in those who court its advent by taking excess of alcohol.

Another eminent physician, who agreed in the main with Dr. Brunton, expressed an opinion that habitual drunkenness may be cured by punishment, and that if its victims were brought under the influence of good education, and some reasonable punishment inflicted, they might

(*a*) Abstract of the Annual Oration delivered before the Medical Society of London, May 6th, 1878

be trained to good habits. I do not think so unless alcohol is rigorously withheld. Some of the worst cases of dipsomania that I have met with have occurred in highly educated individuals, and it is found, by overwhelming experience in the magistrates' court, that punishment has no deterring effect in preventing drunkenness in those who have been two or three times convicted, and who have lost their self-respect and power of self-control. The inconsistence of such an argument is seen at once, for such cases may be epileptic, and yet they are to be dealt with as criminals, and punished accordingly.

It is true that if the alcohol be withheld, the so-called "epileptoid attack" will not come on, for, like the so-called "sunstroke," it is in a great measure caused by the imbibition of the drink, but it is not consistent with our ideas of justice to punish a man because he has had either of the conditions mentioned, which are undoubtedly diseases. The frequency with which the plea of sunstroke is urged as a reason for mitigation of punishment by the drunkard in the dock of a police-court is not a little remarkable, and although I have never myself allowed that plea to be used in arrest of punishment in those cases in which the free will of the individual was manifest beforehand, yet it did sometimes avail when the individual was not a free agent. The plea set up has satisfied me that there is an intimate connection between the embolism which causes the so-called sunstroke, and the alcoholic soaking in which the victims indulged.

Like to outbursts of passion and to other vicious practices, there is an ability to exercise free will at first, but

Facilis descensus Averni,
Sed revocare gradum, superasque evadere ad auras,
Hoc opus, hic labor est.

The work and labour required to return to the right path is greater than most men unaided by restraint are able to use. The battery of nerve force, in which free will and the higher orders of mental powers are produced, is damaged by the reagent and is unable to set up those actions which are required for the production of self-control and self-respect. Thus that which was a vice in its early stages becomes a disease later on in life.

The man who refuses to exercise his own self-control when he has the power, after a time becomes a nuisance and a scandal to society at large. He is slowly committing suicide and is ruining the happiness and probably the worldly prosperity of his immediate relations. He ought to be deprived of his liberty to do wrong to himself and others, until such time as his tissues are restored to that state in which his power of self-control may be regained.

So far the effect of alcoholic drinks seems to be for evil and not for good, and some persons ask very pertinently why they should be retained at all in the pharmacopœia as therapeutic agents, when other stimulants might be used with as much advantage in those cases in which they appear to be required. But so powerful a means for evil, like every similar thing, may be used beneficially if used aright. There are conditions of the body in which it performs a duty more satifactorily than any other stimulant. It seems to preserve the body from decay, performing a vicarial duty, being sacrificed itself, and so saving the patient's life. It interferes with the normal charges which are required for the continuance of health, and retains the products of tissue change in the blood; but in certain forms of disease, when the blood is rendered impure by the retention of those matters which should be excreted if the retention has not been caused by alcohol, and great heat is developed in consequence of the combustion or oxidation of such matters, alcohol seems to take the place of those of the tissues which are oxidising; it lessens temperature and saves the fabric from death. This effect is seen most frequently in some zymotic form of disease; there is a great tendency to sloughs and bedsores, which tendency is materially diminished in those who have had alcohol administered, as compared with those who have not.

The therapeutic effects of alcohol, when exhibited in certain typical forms of fever, are most marked. The cases which require it are those in which there is a dry tongue and skin, no sickness and no indication of cerebro-spinal lesion. If there is any indication of the latter with a moist tongue, stimulants universally do more harm than good, because the tendency is then to increase the congestion upon which the lesion depends. When a case is benefited by alcohol, there is soon produced a lessened temperature, a slower pulse, a moister tongue, and a quieter condition of system generally.

The beneficent effect of alcohol in such cases supports the theory which I hold that such fevers are the manifestation of an action which is taking place in the blood of a person who is not in a proper state of health. Some foreign material is retained, or some matter, which ought to have been excreted, exists there in excess of its proper quantity, a specific zymotic germ or some molecular matter, in a state of change, finds entrance into the circulation, and, finding a fitting pabulum, the specific substance is reproduced in quantity, being matured out of the impure material which ought not to be there, supplemented by some other tissues of the body. The growth of this produces more heat than is ordinarily developed, rising at times higher than that which is compatible with life. It is produced at the expense of retained excreta combined with some part of the body which is necessary to support life. Alcohol in such cases comes to the rescue, interfering with the rapid tissue change, and is itself consumed, whereby temperature is lowered, and the morbid matter is not produced so rapidly as would have been the case if the alcohol had not been exhibited; oxidization goes on at a lower temperature, there is a decrease of the production of carbonic acid, and less hurtful products result.

In these cases the effect of alcohol has to be most carefully watched, and the moment there is evidence of cerebro-spinal lesion or of alcoholic excess its use must be discontinued. I have seen patients in serious danger, which has been brought about by the wine and spirits which has been too freely exhibited, rather than by the disease itself. There is something so utterly repugnant to all moral feeling for a medical prescription to be the instrument by means of which a man is sent *drunk* out of the world, that I need hardly insist in this assembly upon the necessity of watching for the probability of such a result. But in those cases in which the remedy is beneficial, it may sometimes be freely pushed in a marvellous manner with most excellent results. In these cases no catarrh of mucous membrane is produced, such as appertains to the confirmed toper, and which in the latter case is only relieved by another dose, followed by renewed nausea and more dyspepsia.

(*To be continued.*)

ON ASTHMA.

By J. B. BERKART, M.D.,
Assistant Physician to the City of London Hospital for Diseases of the Chest.

(*Continued from page* 424)

DEFINITION, PATHOGENY, AND ETIOLOGY.

II.—Immediate Causes.

2. *Inhalation of Dust.*—Foreign bodies, of different kinds and in various quantities, are at all times present in the atmosphere. The dust in the open air is composed chiefly of inorganic particles, and amounts, as for instance in the streets of Paris, (*a*) to about one-sixth of a grain in every cubic foot. Indoors it mainly consists of organic substances and more especially of living organisms, whose development and multiplication here meet with favourable conditions. So long as those solid particles are undisturbed and are permitted to follow their own gravi-

(*a*) Tissandier, quoted by Eduard Lichtenstein, "Ein Stückchen öffentlicher Gesundheitspflege, &c."—*Berl. Klin. Wochenshc.* No. 46, 1874.

tation their tendency is to settle on some object, and thus far they are harmless. But when an external moving force returns them into the air, they may be brought within reach of the inspiratory current, and thus made to enter the air passages. Their effects vary according to their nature and quantity. Fragments of coal, of iron, of stone, and of glass lacerate the mucous membrane; hairs, feathers, fibres of wool and of cotton, once impregnated with moisture, firmly adhere to the secreting surface, and produce great irritation. Infusoria, of which fifty-six species have been observed in the air, are raised by the wind from drying waters and carried great distances; and though apparently dead, they begin, in contact with the mucus, to loosen the covers which enclose their withering bodies and probably regain a new vitality. (*a*) Algoid cells and fungi are particularly abundant in ill-ventilated rooms; living, and ready to undergo development on meeting with suitable conditions, they rapidly germinate, or are already germinating, when they are deposited in the air-passages; (*b*) some of them form a mycelium or masses of toruloid cells; others produce their characteristic heads of fructification. One circumstance connected with the life of fungi deserves here, perhaps, a passing notice. On watching Botrytis cinerea, taken from a rotten apple, Rindfleisch found that the formation of its spores took place only at night. Subsequent observation has fully confirmed this exclusively nocturnal growth. The want of light had not the same effect, for the spores kept in darkness did not proliferate. (*c*) But whether the organic substances that accumulate during the night in confined places have any influence upon that phenomenon must for the present remain a matter of conjecture: much less is there ground for supposing that the nocturnal appearance of the dyspnœa is connected with the greater vitality of these fungi at the time.

However, the result of such inhalation is invariably the same—fluxionary hyperæmia, and even inflammation, of the affected portion of the mucous membrane. The *colds* which *draughts* produce arise in that way. It is the current of air that lifts the particles of dust from carpets and curtains, from walls and furniture, and brings them in contact with the lining of the respiratory tract. The serious affections of the lungs which develop themselves from a prolonged exposure to foreign bodies in the air, are exemplified by the diseases to which knife-grinders, masons, weavers, and other operatives are especially subject. Little regard, however, is paid to the "invisible nastiness," as Professor Tyndall (*d*) calls it, which constantly exists in ill-ventilated rooms. The bronchitis so often attributed to "cold" is, in reality, due to the inhalation of fragments of glass and stone (*e*) which on *post-mortem* examination are found in the air-passages, or to the fibres of wool which are seen in the larynx and appear in the sputa. (*f*) Organic substances are even more powerful. The influence of Chætomium elatum and Penicillium glaucum has already been mentioned. (*g*) The accidental inhalation of a small quantity of flax meal has been known to produce intense bronchitis and dyspnœa. (*h*) The dust-like spores of a large puff-ball caused in the same way so great irritation of the air-passages that the patient was confined to his room for several days. (*a*) In isolated instances the appearance of an asthmatic seizure may be directly traced to foreign bodies in the air, such, for instance, as mustard and ipecacuanha powder. In the majority of cases, however, the exciting cause escapes detection. But it is well to remember that asthmatics are particularly susceptible to that kind of irritation. Not only is their respiratory surface always more or less diseased, but the chronic congestion of the nasal mucous membrane, or the presence of a nasal polypus, forces them to breathe through the mouth, and thus deprives them of the important filtering apparatus. When the nose is pervious, foreign bodies do not reach further than the pharynx; but when that canal is obstructed, they readily enter, not only the bronchi, but are found also in the substance of the lungs. (*b*) Pulverulent bodies penetrate even to the bronchial glands. (*c*)

The inhalation of pollen gives rise to the peculiar symptoms known as *hay-fever* or hay-asthma. Ever since attention has been directed to them, their origin has been connected with the hay season, but has been erroneously attributed to the influence of heat and light, or to the odour of certain plants. Mr. Wyman persists in this error, and still maintains that hay-asthma is a purely nervous affection. (*d*) But the researches of Dr. Blackley (*e*) have conclusively established the dependence of the disease upon the presence of pollen in the air. He found that from the end of May to the end of July the atmosphere of certain localities contains pollen grains in varying quantities. A small portion of that substance, even less than one-two-hundredth of a grain in weight, causes, if directly applied to the mucous membrane of the nose, within five minutes, occlusion of the nasal passages with sneezing and lachrymation. The inhalation of a larger portion of it is invariably attended by a sharp attack of asthma. The severity of this abates with the diminished production of the agent, and disappears altogether when this ceases to be generated. This irritating effect is possessed by the pollen of all plants, but more especially by that of the Graminaceæ, or among the cereals by that of rye.

The action of pollen upon the mucous membrane may perhaps be explained by its behaviour in contact with water-vapour, and also with mucus. (*f*) Under the microscope, pollen appears as a simple cell, with granular contents, and a cell-wall, consisting of an outer and an inner membrane. The extine is coated with an oleo-resin, of a rich amber, or, at times, a pale straw-colour, and contains several slits or pores, across which the intine is stretched so as to impede the escape of the granular matter. It does not appear that the oleo-resin has any specific action beyond enabling the grains to adhere to objects to which they may approach. On the addition of fluid, the cell is distended; the inner membrane projects through the slits of the outer in the shape of small mastoid processes, to which the granules are attracted. A further distension causes the membrane to burst, and the granular contents are, with a considerable force, ejaculated into the surrounding fluid. These granules irritate the mucous membrane, especially the mucous glands, and reappear finally in the sputa, resembling zoogloœa masses. (*g*)

Dr. Salisbury (*a*) attributes the cause of hay-asthma to the presence of an animalcular organism, the *asthmatos ciliaris*. This parasite is said to inhabit stagnant as well as running waters, and to develop itself also on fermenting organic matter. It is said to be spherical or oval in shape, and to consist of a simple sac, with one or more large nuclei, and many smaller granules of various sizes. The sac itself is armed with cilia, and, between them, with a long proboscis. The young are developed within the parent cell, and are discharged from the end opposite the cilia. Dr. Salisbury's statements, however, have not yet been confirmed by any other observer.

E. Lewy (*b*) observed asthmatic seizures as an isolated affection in 26 out of 1,186 cases of saturnismus. He attributes the dyspnœa to the lead dust, which, from the packing of white lead and the cleaning of type cases, escapes into the air. The inhalation of the lead dust is immediately followed by dyspnœa, palpitation, stitches in the diaphragmatic region, and cough. In from six to seven hours the typical attack of asthma is developed. Lead appears to contract the vessels upon which it acts, while those that escape its influence become congested.

3.—*Thermal Influence.*—There is a widespread belief that "cold," by inducing bronchitis, is a frequent provocative of asthma. Every patient knows instances, where he himself or his friends suffered from dyspnœa, which he could account for only by a loss of temperature. His opinion fully accords with the prevalent doctrine on that point. Clinical observers of the highest repute constantly advert to the danger of a chill, and maintain that, even in well-appointed hospitals, a patient in bed may "catch cold" (Lebert). Indeed, so powerful and so ubiquitous is this agent, that, according to the text books of medicine, it is at the root of almost all diseases, from cerebro-spinal meningitis to diarrhœa; from acute rheumatish and endocarditis to a sneezing fit.

Formerly it was supposed that a chill checked the cutaneous perspiration, and that an excrementitious substance, retained in the blood, produced inflammation of internal organs. The varnishing of animals, and the serious symptoms that generally follow these experiments, unless proper precautions are taken, were supposed to confirm that opinion. (*c*) No poisonous substance, however, was found in the blood, and it was soon admitted that the symptoms of varnishing do not correspond to those of "colds." That theory therefore was abandoned. At present the cause of the disease is sought in disturbances of the economy of heat. Two different views are held on the subject. According to the one, a *sudden* change of temperature, however slight it may be, produces one-sided radiation of heat, and leads through the vaso-motor nerves of the skin to circulatory derangements of internal organs. Professor Pettenkofer insists on the *suddenness* with which the loss of temperature is effected. The difference between the rapid and the gradual abstraction of heat may, in his opinion, be compared, so far as the results are concerned, to a man going or falling down stairs. (*d*) But if one-sided radiation had really such injurious consequences, there could not be a more dangerous instrument than a fan in the hand of a lady. As a matter of fact, it is not so dangerous as alleged; and the reason is that if, adopting the simile, the man were of caoutchouc, or, at any rate, provided with the same elasticity as the regulators of temperature are endowed with, it would be perfectly immaterial, so far as the consequences are concerned, in what manner he descends. Rosenthal (*e*) equally regards the *suddenness* of the changes as the cause of "cold." His experiments led him to conclude that when an overheated animal, in which the cutaneous capillaries are paralysed, is suddenly exposed to a lower temperature, the blood is rapidly cooled, and in that condition it is returned to the internal organs. It then produces inflammation of those parts that are "loci minoris resistentiæ." In man, a *rise* of temperature follows the application of cold to the heated surface, (*a*) and there is little doubt that the same law holds good also in animals. But the *sudden return* of the blood implies a contraction of the cutaneous vessels; and, as their paralysis is essential to the cooling, there cannot be a great loss of heat; or, if the vessels were paralysed to the extent that they have lost their physical property of contracting upon the application of cold, no blood could be returned from the surface to the centre. Without entering upon the questions that are involved in this subject, it suffices to say that over-heated (*i.e.*, febrile) bodies *do not catch cold*. A reduction of their temperature tends to re-establish the healthy balance. The success of modern anti-febrile treatment is based upon that principle, which a thousandfold experience has shown to be correct.

According to another view, "colds" arise from an appreciable loss of temperature, such as is produced by currents of air and copious evaporation from the perspiring skin. (*b*) Hirsch concludes that "colds" are most frequent when the temperature and the dew-point of the air approximately coincide, as in spring and autumn. (*c*) The opinion of Hirsch is, at any rate, based on very extensive statistics; and it is deduced from incongruous facts, which allow no other generalisation. Yet meteorological reports, on however vast a scale, are alone insufficient to solve this obscure problem. At the present stage of civilisation, every individual creates for himself, or otherwise obtains, an atmosphere in which he thrives or decays. The state of the weather will undoubtedly affect, in a different manner, the inhabitant of Belgravia and of Bethnal Green. Both may bestow the same anxious and efficient care to ward off the cold; yet, while the one escapes unhurt, the other catches bronchitis. The influence of the weather would here be very remote. Its injuriousness would be admissible only if it could be shown that those who most expose themselves to the supposed cause, are also the most frequent sufferers of its assumed consequences; and herein statistics not only fail, but prove just the opposite.

These considerations are dictated by what daily experience suggests, and they are decidedly adverse to the prevalent doctrine. It is needless to refer to those well-known instances where delicate as well as strong persons daily sustain, deliberately or unconsciously, considerable losses of temperature. Yet in no single instance has such loss *alone* produced inflammation of an internal organ. The question is not whether cold can, under no conditions, be hurtful. Nobody doubts that, if an animal be kept in a tin box surrounded with ice, the temperature of the body will decrease to 18 or 20° C., and that death may thus ensue from paralysis of the heart and œdema of the lungs. (*d*) These are *experiments* that happily have their counterpart but rarely in practice. But that is not the point at issue. The supposition is that if a few square inches of skin were denuded of their customary covering, and exposed even to the warm temperature of a room, the consequence would be an inflammatory affection of the muscles or of an internal organ. (*e*) Let the worst that may, happen in such a case. Let the blood in that circumscribed space, and even to a certain depth, exchange its temperature with that of the atmosphere. Let the vessels at that spot be contracted, and the mass of blood

in other organs be correspondingly increased. What can follow from all this? The body produces more heat than it can retain, so that the loss is readily compensated. The increase of the vascular pressure would not sensibly influence even that of the muscles of the extremities, where such differences are generally balanced; and since ligation of the abdominal aorta does not produce hyperæmia of the lungs, it can hardly be expected that the quantity of blood displaced from a few square inches of skin could have that effect. Granted even that a hyperæmia resulted, there is still a wide difference between the temporary turgescence and inflammation. But facts are altogether opposed to that theory. Jürgenssen rapidly reduced the rectal temperature of a man to 33° C.; but this man, neither at the time nor subsequently, felt any inconvenience from the experiment to which he submitted himself. (*a*) Another, having spent a whole winter's night in the open air at a temperature of—6° C., is brought to the hospital with a rectal temperature of 24° C.; and within thirty-six hours he leaves the institution in perfect health (Nicolaysen). Conceding that the favourable issue of both these cases may in a great measure be attributed to individual peculiarities, still it shows not the less that the fatality generally ascribed to cold is greatly exaggerated. There is, of course, the unanimous assertion of almost all patients that they can distinctly trace their disease to the influence of that agent. But much of this opinion is, doubtless, due to the circumstance that the laity and physicians are accustomed to consider the presence of a bronchial affection, more especially, as a cogent proof that the patient *must have caught a cold*. And under these circumstances it is not difficult to recall the occasion when the cooling has taken place. Much, however, is attributable to this, that all inflammatory affections, whether slight or intense, local or constitutional, are ushered in, or are often for days preceded, by chilliness or rigors, while the causes of these (*i.e.*, the local changes) only subsequently appear. No disease is attended by more pronounced constitutional symptoms than pharyngitis; and here the febrile movement, cold followed by heat, is felt for days before the difficulty in swallowing is noticed. Thus the first expression of the disease is often taken for its cause; and this mistake will be readily intelligible from the disagreeable sensation which cold in general occasions.

Is then the economy of heat really disturbed so easily as supposed? Are the regulators of the temperature so powerless towards even a slight disturbance? Surely, the regard to the compensatory forces—the operation of which no organic processes exhibit in so striking a manner as those connected with animal heat—suggests a negative reply. Amidst the most varying external and bodily conditions, the healthy organism preserves its own daily temperature at an average height of 37·2° Cent. Within wide limits every loss of heat is compensated for by an increased production, and every excess of heat is rectified by an increased expenditure. This regulation proceeds from an excito-caloric and a moderating centre, to which thermal stimuli are probably conveyed from the periphery. (*b*) But it is carried out by the cutaneous capillaries, and here it is subject to the physical laws of temperature; cold contracts the vessels of the skin and forces the blood to the centre, or rather into the muscles; heat, on the contrary, dilates the vessels and favours perspiration.

It depends, therefore, upon the energy of the vital functions and the persistence and intensity of the disturbing element, how far the limits of the compensation reach. It is evident that those limits must necessarily vary in different individuals and at different times. Upon the whole, the body is better able to withstand cold than to dispose of its superabundant heat. The living organism produces, irrespective of food, two million calories in twenty-four hours; and this supply may be maintained or increased by various means, so as to meet every conceivable emergency. The difficulty at times is, as already mentioned, to remove the surplus, which, if accumulated in the body, would, in twenty-four hours, raise the temperature to the fatal degree of 48° C. (*a*) The efforts in one direction are invigorating; those in the other have a debilitating effect. The local action of heat and cold presents the same difference, inasmuch as a slight increase of the temperature is destructive of the tissues, while even a considerable reduction of it merely renders their vitality latent. The frozen muscles of the frog retain, when thawed, their electrical irritability (Kühne). A comparatively slight increment of heat, on the contrary, coagulates the myosine of muscles and destroys their vital properties. Similar changes are observed in the blood; extreme degrees of cold are to the life of the red blood-corpuscles far less prejudicial than is even the febrile heat of the body. (*b*) A rabbit's ear may, with perfect impunity, (*c*) be exposed to a temperature of—6° C. for from twenty-five to thirty minutes. Its exposure to a temperature of from + 46 to + 49° C. is attended by œdema of the surrounding tissues, and at + 50° C. the emigration of white blood-corpuscles commences. (*d*) The reaction of a rabbit's ear naturally differs from that of a human lung, and the changes observed in the former allow no such direct inference as those that may occur in the latter. Still, these experiments justify the conclusion that the "cold" to which the lungs are exposed cannot possibly have the noxious consequences usually attributed to it.

Although the injurious influence of cold has been grossly exaggerated, yet it cannot be denied that asthmatics may suffer from dyspnœa, in consequence of a considerable loss of their temperature. Their organs of respiration and circulation would not only be greatly taxed, but might even fail to meet the consequent increased demand for oxygen. (*e*) In what manner the pulmonary surface is, under such circumstances, affected is not quite known. The face and hands of delicate individuals exposed to cold become cyanotic, because the arterioles are contracted, and the veins are gorged. But it is impossible that in the lungs the arteries can be so contracted or the veins so gorged as to produce the same degree of cyanosis. For not only is the inspired air warmed on its passage through the nose, but the bronchial surface is far more vascular than the skin, and much nearer to the centres of the production of heat. (*f*)

Over-heating is a more potent and also a more frequent cause of dyspnœa than cold. It is well known that asthmatics greatly suffer in hot and sultry weather. Trousseau considers asthma as a disease most prevalent in hot climates and in the summer; (*g*) but his observations are not quite to the point, inasmuch as they include also *hay* asthma, which he ascribes to heat and light, instead of the inhalation of pollen. The dyspnœa must be attributed to the imperfect disposal of the superabundant heat when the warm atmosphere is saturated with moisture. The pulmonary surface is probably then in a similar œdematous condition as the skin. The

heated blood irritates the centre of respiration, (*a*) and also that of the vagus (Cyon). The volume of the expired air increases, but the exhalation of carbonic acid diminishes, not on account of its deficient formation, but because the oxygen loses, in a ratio corresponding with the rise of temperature from 0° to 37° C., the power of expelling that gas. (*b*)

Over-heating is not a less active cause of asthma in the winter season. There are numerous persons, in all stations of life, who at all times consume more than the necessary quantity of food, who, particularly in the winter, overburden themselves with warm clothing, and spend their time in hot and ill-ventilated rooms at the fireside. That food, and *à fortiori* an excess of it, as well as the products of the faulty digestion, do increase the bodily temperature, has been abundantly ascertained by exact thermometric measurements. Besides, the flushing of the face, the trobbing of the arteries, and the palpitation of the heart, from which those individuals generally suffer after meals, sufficiently indicate a febrile movement. Yet the disposal of their superabundant heat is a matter of considerable difficulty. The loss of the lungs is slight, because the air of the rooms is thoroughly warmed. The skin, even if no thick layer of subcutaneous fat impedes radiation (*c*)—and the obese are the most numerous among that class of persons—is, on account of the great amount of clothing, surrounded by an atmosphere of a'most the same temperature as that of the body. Among th se who seek advice at hospitals, it is often seen that even the robust men are in the habit of wearing in the winter—1, a thick overcoat; 2, a frock coat; 3, a thick waistcoat; 4, a flannel shirt; 5, a flannel vest; and 6, a chest protector or "cat's skin," all these "to keep their chest warm." And the same anxious care is bestowed upon the clothing indoors. Under these circumstances Nature relieves itself by copious perspiration, and thus, by the evaporation of the perspired water, endeavours to reduce the temperature. The disagreeable sensations that are apt to arise from this cooling process, are regarded by the patient as a sure sign that "he must have somehow caught a fresh cold." And such is the vicious circle, that the means which he now adopts to combat only increase the evil. But although the regulators of the temperature succeed in preserving it for a length of time at its normal height, there is little doubt that they ultimately succumb to the prolonged strain upon their energy. This failure will not appear unexpected, if it be remembered that the mainsprings of that regulation are the cutaneous arterioles, or rather their muscular coats, whose continued relaxation would, even in the absence of any other cause, greatly derange their nutrition. If this much be admitted, it is needless to trace the steps that lead to the retention of heat in the body—a truly sub-febrile condition. Now, it is known that in insulation, death is due to the degeneration of all parenchymatous organs, and especially of the heart. (*d*) The danger in acute infectious diseases arises from analogous causes. Experiments on animals, by exposing them to a high temperature for some time (36° C. for thirty-six hours), (*e*) are attended by the same results. Not only the liver, the spleen, and the kidneys, but the entire muscular system, including the coats of the arterioles, undergo fatty or similar degeneration, these changes being then particularly marked in the substance of the heart. (*f*)

As such derangements of nutrition are invariably produced by a *high temperature* of only a *short duration*, it cannot be doubtful that the prolonged action of a *lesser* degree of heat must have similar consequences. Indeed, it appears that such is the case in those who most emphatically declare their susceptibility to "catching cold." One acquainted with their habits of life will readily concede that they seldom or never give *cold* the least chance of exerting its injurious influence, but that they suffer from the consequences of overheating. Their vessels are dilated and degenerated; serum, and even white blood-corpuscles, escape on the slightest provocation. A heated room, the irritating gases—the products of respiration and combustion, such as accumulate in the air of a theatre—and the dust which a current of air, *the draught*, raises from the ground: these suffice to produce the supposed effects of "*catching cold.*"

Clinical Records.

CASES IN PRACTICE.

By JAMES MARTIN, F.R.C.S.,
Portlaw.

DEC. 3, 1877.—I was called to a woman in her fourth confinement. All the previous ones had been natural, except that the last, like the present one, occurred without any assignable cause at the end of the eighth month.

When I arrived, she had been four times in labour. I found the pains so violent and expulsive in their nature, that they brought the os uteri, if I may use the expression, down to the os externum; yet the os was not distended more than the size of a half-a-crown; its edge thick, hard, and tense, the membranes protruding, but no presentation to be felt.

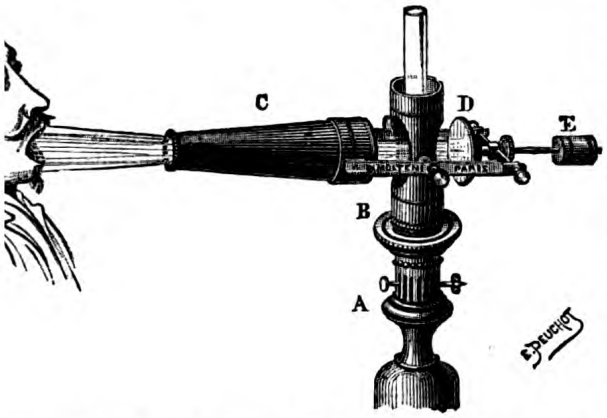
I gave two doses of chloral, three grains each, at intervals of an hour, and after some sleep, the pains again became violent, and ten hours after the os was dilated to double the size, its edge thin, but tense as a harp-string, and still no presentation to be felt. I therefore ruptured the membranes, and at once found that a shoulder presented. The pelvis being roomy, and the vagina soft and cool, I at once introduced my left hand with a view to turning, but finding that the passage of the hand through the os during such violent labour would be difficult, and remembering Dr. Barnes' instructions for the treatment of such cases, I passed my right hand between the patient's thighs on to the abdomen, and found that I could seize the head, and while tilting the shoulder up with the finger of the left hand, thrust it into its normal position in the pelvis; then withdrawing my left hand, I applied the short forceps on the head, and finished the labour in a few minutes. The child, a weakly one, lived 24 hours, and the mother made a good recovery. In a former case, which I saw in consultation, I attempted bipolar version, and though I failed in my effort in consequence of the length of time that the arm was protruded, yet I saw enough to teach me that as yet attention is not sufficiently paid to this easy method of avoiding one of the most distressing and laborious operations in obstetric manipulations.

WILLIAM CAMPBELL, the Scottish giant, died on Sunday last, at Newcastle-on-Tyne, at the age of 26. Campbell had been exhibiting in London at the Egyptian Hall, and returned to Newcastle, intending to stay only a few days. He stood 6 feet 3 inches, weighed 52 stone, measured 96 inches round the shoulders, 76 round the breast, 47 round the thigh, and 35 round the calf of the leg. He was the biggest man in the United Kingdom, and, so far as report goes, in the world.

Novelties.

CADIER'S LARYNGOSCOPE (POLY-ENDOSCOPE.)

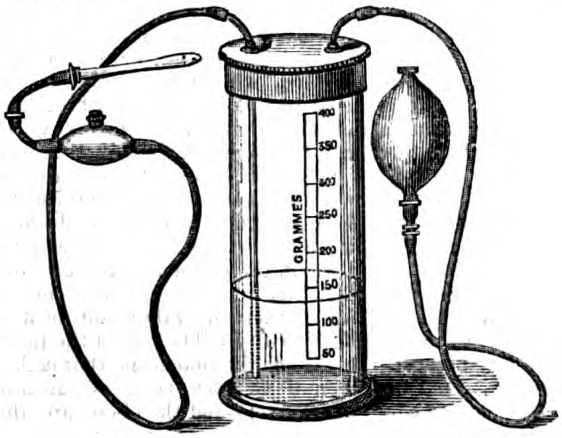
Dr. Cadier, of Paris, has recently introduced a new form of laryngoscope, which he has used with great success. Thanks to the powerful method by which it is lighted, one can see perfectly by its aid the smallest details and farthest points of the larynx. This instrument has been presented to the Academy of Medicine by Professor Peter, whose approbation on such a subject is the best proof the medical public could have of its utility and special advantages of this new instrument. At the meeting of the Academy of Medicine this instrument was presented, its design being to throw to the bottom of the larynx the largest possible quantity of light. That object had been already obtained more or less completely by other apparatus, Drummond's light and the electric light being used. But these machines were very expensive, difficult to be adjusted, and easily put out of order, all of which reasons tend to give the monopoly to the laryngoscope. The idea is to get from an ordinary lamp sufficient light by concentrating all the rays which it emits. This is what has been attempted—and successfully—by Dr. Cadier in his new instrument, of which the essential elements are a reflector and two lenses—one concave, the other convex. This apparatus not only concentrates the light, but is also very convenient, as you can attach it to any lamp or table. It also possesses absolute mobility in a vertical and horizontal direction, so that the luminous pencil can be easily directed upon all parts of the throat. It must also be remembered that with this instrument the observer can stand directly behind the light without being inconvenienced by it. Dr. Cadier's laryngoscope also possesses an advantage which is not to despised, for it causes the patient to stand at a distance, and thus protects the observer from the offensive emanations of a sore throat. For all these reasons—its convenience, is easy adaptability, and its moderate price, Professor Peter considered himself justified in presenting Dr. Cadier's instrument to the Academy, and recommending it to the medical public. This way of lighting the larynx, and the intense light which can be obtained, is equally applicable to other cavities for the exploration of which a strong light is required—nose, ears, and vagina. It may therefore be called a poly-endoscope.



Description :—A, ordinary oil lamp ; B, socket carrying the laryngoscope on two pivots so as to regulate the height ; C, copper tube with lens ; D, reflector ; E, counterpoise. The parts C, D, E are joined by pieces of copper, and balanced on the pivots, which allows it, by the aid of a clamping-screw, to place the light in the wished-for direction.

INJECTION APPARATUS.

At a recent meeting of the Academie de Médecine of Paris, M. Beclard presented, for M. Léard, an injection apparatus without piston or stop-cock. It is constructed, as shown in the adjoining illustration, of a glass receiver,



of a capacity of 500 to 1,000 grammes and graduated ; the upper end is embraced by a metal ring, into which a cap is screwed having two tubulures. Two tubes pass through these openings, to one of them an elastic tube and hand-ball are connected, while the other gives passage to a tube which extends nearly to the bottom of the receiver, and its upper end has a discharge pipe affixed. In the course of the discharge pipe a glass bulb is inserted, having a side opening for the introduction of a medicine to be acted on by the current of fluid.

Compression of the hand-ball creates a pressure of air inside the receiver, and causes a steady flow of fluid through the discharge pipe. By reversing the hand-ball, the apparatus will at once be converted into an aspirator.

UNGUENTUM PETROLEI.—(HOUGHTON AND CO., PHILADELPHIA.)

This is a bland unirritating substance greatly excelling lard for the pharmaceutical purposes to which the latter is applicable. It does not become rancid, and can be used as a vehicle for many materials that require to be employed in the form of ointment. It forms an elegant disinfecting lubricant when mixed with two per cent. of Thymol, and is therefore very useful for obstetrical purposes, as was pointed out by Dr. Wiltshire two or three years ago at the Obstetrical Society. We commend it to the attention of our readers.

Small-pox caused 48 deaths in London, and 21 in Dublin. In the former the epidemic appears to be gradually subsiding, whilst in the latter it is increasing in intensity.

The annual rates of mortality, according to the most recent weekly official returns, were—in Calcutta 43, Bombay 41, Madras 44 ; Paris 25 ; Geneva 21 ; Brussels 25 ; Amsterdam 26, Rotterdam 26 ; Copenhagen 23 ; Stockholm 26 ; St. Petersburgh 66 ; Berlin 29, Hamburg 26. Dresden 23, Breslau 26, Munich 34 ; Vienna 38, Buda-Pesth 42 ; Rome 26, Turin 33, Venice 23 ; Alexandria 43 ; New York 27. The 848 deaths in St. Petersburgh included 190 from fevers.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, MAY 29, 1878.

THE NEW MEDICAL BILL.

WITHIN the last week the Duke of Richmond and Gordon has been overwhelmed with medical deputations respecting the Conjoint Scheme and other subjects dealt with in this Bill, but we cannot say that any one of them was successful in exacting from his lordship any such amendments of his Bill as will satisfy those who are bent upon a genuine and radical medical reform. There was a deputation from the Medical Defence Association, from the University of London, from the Royal College of Surgeons of Dublin, and from the Medical Alliance Association; but had there been half-a-dozen more deputations, it is evident they would not have induced the Lord-President to make concession on all the points which the profession was most anxious should be conceded.

With regard to the Conjoint Scheme, the Duke of Richmond and Gordon, who is evidently anxious that it should be tried in England, told the deputation from the University of London that he did not think if there was a Conjoint Scheme for England, comprising all the Universities and corporations, that, therefore, many young men wishing to enter the profession, and not wishing to pass the examination of the Conjoint Board, would take refuge in Scotland, on the ground that they would pass a milder examination than would be exacted from them by the Board, for so long as the Medical Council existed, it had the power and the duty imposed on it of seeing that the examinations were of such a character as they thought they should be, and as would uphold the dignity and credit of the profession. This is certainly a very nice way of getting out of the Scotch difficulty. Have, his lordship would say, a Conjoint Board in England by all means, and the Medical Council will see that the Scotch corporations make the standard of their examinations quite equal to that of the English Conjoint Board. This is, however, a "sop" which is not likely to silence the convictions either of the profession at large, or of those associations above mentioned by which the profession has been recently represented. It would be impossible for the present or any prospective Medical Council to exercise such constant supervision over the examinations of the Scotch examining bodies as would ensure an uniformity of examinations among themselves, much less an uniformity with the examinations of the English Board. We might hope that the self-respect and ambition of our medical students would induce the great majority of them to present themselves before a Board whose very constitution, independently of its examinations, would give a dignity to its licence which would not appertain to any licence granted in Scotland. We could not hope, on the other hand, that the disinterested zeal of the rival bodies in that country in the cause of medical education would prompt them to put their examinations so closely on a par with those held in England as should hold out no hopes of a student obtaining in one country what he could not obtain in the other.

Then, again, if we do not misunderstand what the Lord President told the deputation from the Medical Defence Association, he is willing to make the Conjoint Scheme compulsory in each division of the United Kingdom upon all the corporations, except the Universities. Such a proposal will never be sanctioned by the profession; but as, in our last issue, we entered fully into the reasons why medical reform cannot be accepted on any such terms, we shall now only repeat that such a scheme would be fatal to the very object which the Bill aims at attaining. For not only would there then be a rivalry between these imperfect Conjoint Boards and eleven Universities, but in many cases the standard of the Board's examinations might be lowered through the absence of any representations of those Universities that have been foremost in their endeavours to promote the causes of medical education and to raise the standard of their professional examinations.

But we may ask, why all this talk about the "difficulties" thrown in the way of conjoint examinations by the Scotch bodies? Are these difficulties such that they might not be surmounted by a little timely concession on the part of those bodies? We think they might, and for the following reasons: In the first place, a committee might be formed to elect examiners for a Conjoint Scheme. Secondly, when a candidate has passed the Conjoint Board he still has no title to practise; therefore he must go to one of the present Scotch Examining Boards, and pay the sum charged by that Board for their examination, deducting, of course, the fee previously paid to the Conjoint Board. He then takes their diploma, or more than one, without further examination. Thirdly, the fee above mentioned (say £5) is charged to each candidate, and shall go entirely to pay the expenses of the Conjoint Board. Fourthly, it is here presumed that the conjoint examination will be sufficiently severe to satisfy most of the present examining boards, but should a University

think the Board examination not sufficient, it can, by previous arrangement, give it to be understood that any candidate desiring its diploma or degree, must, in addition to passing the conjoint examination, pass also an examination in certain named subjects at the University before being able to claim that degree. By some such arrangement as this the Scotch bodies would be sacrificing very few of those vested interests which have been so generally supposed to stand in the way of their uniting to form a Conjoint Board. But the question, perhaps, is not so much one of "ways and means" as of the *will* to adopt them. Either through prejudice, or from a conviction that Conjoint Boards are uncalled for and would not fulfil the objects for which they are projected, or from both these reasons combined, the Scotch bodies have evidently, as was seen when the subject was discussed by the Medical Council, entirely set their faces against all Conjoint schemes whatsoever. Wedded, therefore, as Scotland is to the interests of her own corporations, instead of to those of the public and the profession, it is evident that unless compelled to do so she will not lend any support to the Conjoint Scheme, notwithstanding it has received the assent of the General Medical Council, the English Corporations, the British Medical, and other Associations interested in the matter, the great majority of the profession, and the medical press. For this reason, we may be glad that, as the Duke of Richmond and Gordon announced to the House of Lords last Friday, amendments will be introduced into the Bill, which will compel the corporations in the three divisions of the kingdom to form Conjoint Boards. So far the Scotch bodies may be said to be checkmated, but then again, while the "Scotch difficulties" are thus partially removed, there will now be another difficulty in consequence of the Universities being left out of the question. At the same time we would ask, is the whole scheme of Conjoint Boards to be completely shipwrecked because the Universities are to be allowed to stand aloof? We say, certainly not. In our opinion it would be wise if the Royal College of Physicians of England, the Royal College of Surgeons, and the Apothecaries Society were to take independent action in spite of what will now be called the "University difficulty," and whatever may be the fate of the new Medical Bill. To their credit be it said, they have from the very first approved of and done all in their power to promote the Conjoint Scheme. Let them now rely upon the propriety, and, indeed, the necessity, of the proposed change. Let them take the initiative in a movement which is not only made in the interests of the public, but a movement which has been long and earnestly called for by the great bulk of the profession, from whom, too, they will not lack support if, in spite of the obstacles in the way, they have only the moral courage to undertake with spirit and with confidence that task which has been so unworthily shirked in other quarters. They may have, moreover, support and encouragement in one quarter in which, in the opinion of some, they should least expect it, namely, the great and important body of medical students in this great metropolis. We have not such a poor opinion of the spirit and generosity of the gentlemen who fill the lecture-rooms of our medical schools as to suppose they will avoid a Board, in the constitution of which their own individual interests have received no little consideration. There may be, unfortunately there are, a few idle students in every medical school, but we are sure the good sense and laudable ambition of the great bulk of our medical students will prevent them from seeking in Scotland what they could better, and with more dignity, get in their own country. Should a Conjoint Board be formed in England while the Scotch corporations are still open to any candidates who may think proper to apply for their licences, it will be reposing a confidence in the spirit and better feelings of medical students which they will not, in our opinion, be slow to acknowledge. The Scotch bodies will then find that they have gained nothing by their obstinacy. The English bodies will find that they have gained everything by their perseverance and moral courage—the gratitude and thanks of the public and the profession, and the respect of those who present themselves for their conjoint examinations.

EIGHTH REPORT OF THE OPERATIONS OF THE CONTAGIOUS DISEASES ACTS.

Sir Harcourt Johnstone's motion for the second reading of this Bill for the repeal of these Acts was not more successful than on previous occasions. It will be remembered that in July, 1876, there was a great debate in the House of Commons on the subject, but the debate and division were no less satisfactory than those which had preceded them; and the Bill was rejected by a majority of 122 in a house of 326 Members. This time the debate did not lead to a division, but was brought to an abrupt ending by Mr. W. H. Smith talking down the honourable baronet to the time of adjournment. As might have been expected, Sir H. Johnstone had no other facts or arguments to bring forward in support of his Bill than those which have been so often harped upon by the opponents of these Acts. In our last issue we briefly answered most of those "Reasons" for the repeal of the Acts which a certain association has very recently published, and now we will supplement the remarks we made on that occasion by a reference to the last report which has just been made by the sub-committee of the Association for the Extension of the Acts.

With regard to the effects of the Acts upon the army we need not recapitulate the facts which have already appeared more than once in the columns of the Medical Press and Circular, but we are reminded by the report before us that the reduction which is recorded does not represent the whole advantage derived from the Acts, and which would result from them were their operation further extended. For, at the protected stations the ratio is often increased, because a considerable proportion, sometimes as much as half of the men under treatment contract their disease outside the district; and the rate is also continually augmented by the influx of diseased men from unprotected stations, while in the returns the latter stations get all the advantage of the constant transfer to them of men with a low rate of disease. This fact has been very disingenuously taken advantage of by the oppo-

nents of the Acts, who, by ignoring the conclusion to which it inevitably leads, have rarely put before their supporters the bare statistics; which, unless the allowance above referred to is made, represents the Acts in a comparatively unfavourable light.

With respect to the Navy, the effect of the Acts has been well shown by a return moved for by Sir Harcourt Johnstone in July, 1877, which gives the ratio of venereal disease in the crews of ships stationed at five home ports under the Acts, and at five ports not under the Acts, from 1860 to 1875. The result as regards the diminution of the more important form of disease, syphilis, corresponds very closely to that obtained in the army. Thus, in the years 1860-63, before any Acts were passed, the average annual ratio of syphilis was 75·02 per 1,000 at the five ports since placed under the Acts; and 70 05 per 1,000 at the five ports not placed under the Acts. In the years 1870-75, with the Acts in full operation, the average annual ratio was 43·52 per 1,000 at the protected, and 96·37 per 1,000 at the unprotected stations, so that, latterly, the amount of disease at the former has been considerably less than half that recorded at the latter. The ratio fell 31·45 per 1,000 at the one, but rose 26·32 per 1,000 at the other. The cause of this rise at the unprotected stations, whatever it may have been, was, probably, also in operation at the others, and would have shown itself in them, had it not been kept in check by the influence of the Acts, which should be credited, therefore, with the prevention of the rise as well as with the positive diminution. The difference, therefore, comparing the two sets of stations before and after the Acts, amounts to 57·77 per 1,000 in favour of the protected stations.

As regards gonorrhœa the result is not so satisfactory, for there has been a considerable rise in recent years; but this increase is explained by the Director-General, Sir Alexander Armstrong, by the fact that previous to passing of the Acts, it was not the custom to place cases of gonorrhœa, unless severe ones, on the sick list; and thus the majority of cases were not recorded. This apparent increase of gonorrhœa has been made the most of by the opponents of the Acts, who either pass over the decrease of syphilis altogether, or keep it in the background as much as possible, and take full advantage of the aggregate increase obtained by lumping the two diseases together. We might notice other illogical calculations or misleading statements that Sir H. Johnstone has made, but we must pass on to another subject, namely, the influence of the Acts on the women in the subjected districts.

As we pointed out last week, one argument of the opponents of these Acts is that while they fail to check disease they also encourage vice, and degrade the women of the districts in which they are in operation. But what do the official reports say? In the first place, the Annual Report of the Assistant-Commissioner of Metropolitan Police, for 1877, states that the women have attended the periodical medical examinations with even greater regularity than in previous years; and that the orderly working of the Acts has been obtained without undue interference with personal liberty is shown by the fact that not a single complaint of excess or violation of duty on the part of the police has been reported. Again, we are informed that wherever a chance exists of reclaiming a woman every effort is made before she is brought under the operations of the Acts. In proof of this statement we are referred to the number of young women who, being found in bad company or in houses of ill-fame, were restored to their friends. By this means, 183 women, 75 of whom were between 12 and 18 years of age, were so rescued in 1877. In addition to these, 134 having commenced an immoral life, abandoned it on being cautioned by the police. Thus, 317 young women were saved from a shameful career without being in any way subjected to the regulations of the Acts. Besides these, 867 others were restored to their friends or were admitted to refuges after having submitted to the regulations for a longer or shorter period. By these means the proportion of prostitutes in the districts under the Acts is kept far smaller than by any voluntary system hitherto adopted, while juvenile prostitution, so rife when the Acts were first put in force, has been almost stamped out.

The significancy of these facts is apparent enough, and may they not also partly account for the circumstance (which Sir H. Johnstone admitted in the House of Commons) that the respectable inhabitants in the towns to which the Acts applied were in favour of them, on the ground that they kept the towns more quiet? This is the more probable when we consider that while "there were 1,694 houses of ill-fame open when the Acts came into force there were only 526 in 1877."

Indeed, so immeasurably stronger are the reasons for the retention and extension of these Acts than the "Reasons" for their repeal, that we are surprised that their opponents are so blinded by prejudice and sentimentalism as to persevere in opposing the measures that the State has thought proper to take for the purpose of preventing these contagious diseases, and the evils resulting from them. We were, therefore, pleased to see that Mr. W. H. Smith expressed his regret that Sir. H. Johnstone had thought it necessary to bring "this most painful question" before the House. He had in his official capacity made personal inquiry as to the operation of the Acts, and come to the conclusion that they had proved beneficial to public morality and advantageous to the State.

COMPARISON OF THE ARMY SERVICE WITH THE CIVIL MEDICAL SERVICE.

THE replies of the various teaching bodies in Ireland to the request of the War Secretary for their opinions as to the causes of the abstention of students from entering the Army Medical Service, would seem not to have satisfied the authorities, even yet, that a change of system is inevitable, and they have accordingly entered upon an inquiry which is intended to afford them a comparison between the money earnings of a medical man in the army and one in Civil practice. It does not seem to us that any such comparison is *ad rem* in the present difficulty, because the refusal of students to enter the Queen's Service has not been at any time in any great degree a question of money. However, here is the letter of the War Secretary.

War Office, April 27th, 1878.

Sir,—In considering the valuable reports which have

been received from the several teaching bodies on the circumstances which tend to deter eligible candidates from coming forward for the Army Medical Service, the committee appointed to inquire into the subject would be greatly helped if they had before them a trustworthy estimate of the average earnings, under ordinary circumstances, of medical practitioners in civil life. I am, therefore, directed by Secretary Colonel Stanley to request that, on behalf of the Royal College of Surgeons in Ireland, you will favour him, as soon as possible, with an estimate on the enclosed form of the average earnings in question.

I am, Sir, your obedient servant,
RALPH THOMPSON.

Estimate of the Average Earnings of a Civil Medical Practitioner.

1.	2.	3. Charges of a professional nature which have to be met out of the earnings shown in col. 2.
Period of Career.		
1 year after obtaining Diploma.		
10 years after do.		
20 years after do.		
Age 50.		
Age 60.		

General Remarks.—To this letter the Council of the Royal College of Surgeons in Ireland sent the following reply :—

Royal College of Surgeons, May 2nd, 1878.

Sir,—In reply to your letter of the 27th ult., I am desired by the President and Council of the Royal College of Surgeons in Ireland to state that they have no data upon which to ground an opinion as to the entire professional incomes of the medical men of Ireland at their varying periods of life.

I am directed, however, to inform you that the civil appointments usually sought for by young men on first entering professional life in this country are those under the Local Government Board, and from inquiry made this day of the Medical Commission of that Board, they find that the average amount received by each medical man holding a dispensary workhouse or other poor-law office is £145 per annum. This source of income is, of course, quite independent of all private practice and that derived from other professional appointments. The Council regret their inability to give any further information in reply to the queries furnished, but it must be apparent that no means exist by which this College could ascertain the incomes received from private practice by individual medical men, and direct inquiries upon this head would be considered inquisitorial on the part of the College.

I am, Sir, your obedient servant,
JAMES STANNUS HUGHES,
Secretary to Council.

The inquiry submitted by the War Office manifests a very regretable want of appreciation of the feeling of the profession on the subject, the causes which have led to the dearth of candidates for the service, and also of the remedies to be applied. Those who are acquainted with the growth of the "strike" amongst students which has placed the Government in its present difficulty, are aware that if the present rate of pay were to be doubled it would not even begin to remove the causes of discontent. Men might, it is true, be bribed into joining an unpopular service, but they could not be bribed into satisfaction with their position when they had entered it, and as long as a student is aware that in entering the service he is trusting himself to any alteration in his tenure and term of office which the authorities see fit, in their caprice, to make, and that in any case he is only making a temporary arrangement for a few years, he will, we presume, have the sense to prefer permanent occupation in civil practice, with the expectation of "bettering himself" as he goes on, instead of serving Her Majesty on a short lease and capricious eviction.

The inquiries put by the War Office are even somewhat foolish, for that institution might be supposed to know that the variations in professional earnings are so great that nothing like an average could be struck which would represent the circumstances of medical men all round. In Ireland the professional earnings of doctors in the large cities varies from *nil* to £3,000 a year, and in the provinces from the dispensary salary to £1,000 or £1,200. Age has not very much to say to the matter, for in large cities there are many practitioners who work hard through life and never make more than £150 a year, while there are others who realise a practice of £1,000 or £1,200 within the first few years of practice. The chances of a young man in practice depend altogether on his opportunities and his capacity, and these are elements which cannot be compared in any respect with the professional advantages of army medical men.

The army authorities need not occupy themselves asking questions. They know perfectly well what they ought to do, what the Service requires, what can be done to meet the difficulty without great expense, and what is reasonable and just towards their medical officers. They would carry into effect these changes to-morrow if they could humiliate themselves to go back of the policy of keeping down the medical officers which they have pursued for so many years—if they could divest themselves of the jealousy which causes them to regard every concession to the doctors as an infringement of the rights of the combatants. This they might do, and thereby remove very many of the grievances of which medical officers complain, and that without costing the country a shilling, yet with every advantage to the service. Until it is done army doctoring can never be acceptable to the gentlemen of the profession.

MR. GLADSTONE ON CHILDREN'S HOSPITALS.

As will be seen in another part of this journal, Mr. Gladstone presided last Thursday at the anniversary festival of the East London Hospital for Children and Dispensary for Women at Shadwell. Mr. Gladstone made a long and excellent speech, in which he drew attention to the unfortunate and yet unavoidable divorce which has of late years subsisted between the rich and the poor of London. "The East-end of London," said the

speaker, "is, to many of those who live in the West-end, a mystery and an unknown land. To most of them— if, indeed, there are many of them who have got so far—it may be considered that the station in Shoreditch is the end of the world, and that to go beyond it would be an adventure hardly to be entertained unless under the most grave inducements. It would seem to them almost like a new voyage of Christopher Columbus in search of a continent beyond the ocean. . . . . We must not conceal from ourselves that, under the conditions of modern life, and with the vast magnitude to which the capital of this country has attained, there are many peculiar causes at work which are tending to separate locally, and in respect to all the material circumstances of life—I mean by material external and visible—one class of the community from another. That is a very grave fact and a very great calamity. It is the duty, I think, of every sensible and prudent, not to say of every Christian man, to endeavour, if he can, to counteract those causes by such means as may be at his command."

Among the causes to which Mr. Gladstone refers are the facts that the wealthy quarters of the town are becoming more and more exclusively the habitations of the wealthy alone, and *vice versa*, while also there is the daily increasing practice of nearly the whole of the middle class seeking, "and very naturally seeking, after the exertion of their busy days, retreat, refreshment, fresh air, health, and renovation—not by their firesides, after the fashion of other generations, but in those beautiful suburbs with which so many points of London have been surrounded and adorned." There can be no doubt that the circumstances to which Mr. Gladstone refers have caused a sort of tacit estrangement between the wealthy inhabitants of the West and the poorer inhabitants of the East end of this huge and overgrown metropolis —an estrangement which would be more complete than it is were it not for the number of people belonging to the middle classes who, engaged in various occupations of business, or of religion or of charity (clergymen, doctors, sisters of mercy, &c.), form a sort of connecting link between those who live in the humble lodgings of the East and those who live in the sumptuous residences of the West. And with regard to our East-end hospitals and other charities, one effect of this estrangement is that they do not always meet with that amount of patronage and support which they probably would get were the benevolent and the rich living more among or nearer that class which stands so much in need of their assistance, and having, through not being so far removed from the East-end, the opportunity of witnessing the poverty, and squalor, and disease that so plentifully abound in that region of the metropolis.

Fortunately, the public press, and the publicity given to such an occasion as that on which we are now commenting, from time to time remind the richer classes that, notwithstanding all our boasted civilisation, and all that is done to maintain the order and well-being of modern communities, society is much the same now as it was in those days when Jesus Christ said to His disciples, "The poor ye have always with you." We feel sure that the more the rich realise this fact, the more inclined they will be to assist by their liberal donations and even their personal co-operation "those laborious and devoted men— clergymen, medical men, and others"—whose sphere of usefulness and whose good work are increased in proportion to the support given to the East-end Hospital for Children and other similar institutions. Before, however, concluding our remarks on this interesting event, we may observe that it should be a matter of regret that there is not more provision made for the treatment of children's diseases at all those hospitals to which medical schools are attached. It is a well-known fact that children constitute half the patients that come under the care of the general practitioner, and yet as regards the diagnosis and treatment of their diseases, a large proportion of our medical students are, through the little opportunity they have of seeing this class of diseases, but ill-prepared to pass an examination on the subject, much less to enter upon practice. This is of course owing partly to the lack of accommodation at most of our hospitals, and partly to the special institutions attracting to themselves patients who would otherwise be treated at the general hospitals. This circumstance is certainly to be regretted, but cannot be easily altered, and all we can do is to advise the medical student who intends to practice generally, to avail himself as much as possible of the opportunities afforded by such institutions as that over whose annual festival Mr. Gladstone has lately so ably presided.

Notes on Current Topics.

The Voice of the Profession respecting Medical Reform.

We stated some time since our opinion, or rather our certainty, that the vote of the ten representatives of Scotch and Irish Colleges in the General Medical Council who voted against conjoint examination was the expression of the money interests of their own colleges, and not only did not convey the feeling of the profession, but was diametrically opposed to that feeling, and we argued therefrom that it was obvious that the direct representation of the profession was most urgently needed when it was found that nearly one-half that body was ready to vote point-blank against the strongly pronounced desires of medical men. Our apprehension of the sentiments entertained by our brethren is completely borne out by the response given to the queries circulated by the British Medical Association. Up to the 18th instant the replies received were as follows :—

	For.	Against.
Direct representation . . .	5,075	. . 121
Conjoint examination . . .	4,910	. . 264

These figures ought to convince anyone of two facts— *first*, that almost every medical man in the United Kingdom considers that the General Medical Council does not fairly represent his views ; *second*, that nineteen-twentieths of the profession are animated with indignation at the petty money-getting policy of the lower class of Licensing Corporations, and desires that those bodies should be forced to do what is right to secure competency in the profession. Medical men might, perhaps, be said to have a personal interest in obtaining a voice in the government

of medical matters, but, as regards conjoint examination, it cannot be said that they have any personal interest in its favour. On the contrary, it is distinctly their interest to make all the money that can be got out of students, and make the road for their ingress as easy as possible. Nevertheless, medical men feel that the licensing of semi-competent persons is a crying sin, and it is well worthy of note that the clamour for improved education comes not principally from the public, who should feel the want of skilful medical attendants, but from the profession, which seeks—at a sacrifice of its own interests—to secure to the community medical advisers of a first-class medical and social grade.

The Irish Medical Association and Medical Reform.

THE following is the memorial addressed by the Council of the Association to the Duke of Richmond. The sense of the memorial was represented verbally to His Grace by Dr. Grimshaw, chairman of the Council of the Association, who was deputed to wait on his Grace in co-operation with the deputation from the British Medical Association.

To the RIGHT HONOURABLE HIS GRACE THE DUKE OF RICHMOND, K.G., *Lord President of the Council, the Memorial of the Council of the* IRISH MEDICAL ASSOCIATION :

HUMBLY SHEWETH,—

That the Council of the Irish Medical Association view with satisfaction any attempt at legislation which may tend to improve medical education and medical examinations, and to remove the present unsatisfactory state of the qualifications which entitled their holders to admission to the *Medical Register*. That the Council have carefully considered the provisions of the "Medical Act (1858) Amendment Bill," introduced into the House of Lords by your Grace, but the Council regret that they cannot regard the Bill in question as sufficiently fulfilling the foregoing objects, for the following reasons—

1stly. That the constitution of the General Medical Council is not affected by the Bill: the General Medical Council, as as present constituted, only directly represents the Government and the Corporations, but scarcely at all the great bulk of the medical profession. That while it is owing to the failure of the Corporations to adopt conjoint examinations, and the omission of the General Medical Council to enforce uniformity of education and examination, that the proposed legislation has become necessary, yet the regulation of examinations is to be almost altogether vested in the representatives of the licensing bodies.

2ndly. That the Bill does not make efficient provision for uniformity of examination, and still leaves the nineteen portals open for admission to the *Register*.

The Council of the Irish Medical Association therefore humbly pray that provision should be made in the present measure for the direct representation of the great body of the profession in the General Medical Council, each division of the United Kingdom being duly and separately represented. The Council further pray that, as experience has proved that a majority of the medical authorities are indisposed to unite for the promotion of conjoint examination schemes, there being in consequence no prospect of a single examining body being formed for each division of the United Kingdom, some power of compelling united action on the part of the said medical authorities should be provided in the bill.

And your Memorialists will ever pray.

The Wholesale Poisoning by Violet Powder.

WHILE this case is still pending it would be premature to say anything with regard to all the circumstances under which these extraordinary cases of poisoning took place ; but we may make a few remarks on the particular and almost unique manner in which the poisonous effects of arsenic proved fatal in these cases. Poisoning by arsenic generally takes place through that metal being taken into the stomach, or inhaled by the lungs, and so seldom has this poison proved fatal through its application to the skin that our text-books of toxicology are almost silent on the subject. Serious symptoms, and even one or two fatal cases, have occurred among people engaged in making artificial flowers, &c., but in these the aceto-arsenite of copper (or "emerald green") was the poisonous preparation, and not arsenious acid itself, besides which the poisoning was caused as much by the inhalation as by the handling of the metal. Cases, however, are on record in which arsenic itself was criminally administered through very extraordinary channels. Thus Fodéré mentions an instance it which a lady was poisoned by arsenic which had been administered in enemata, while Dr. Mangor (quoted by Christison) related three instances in which three women were killed by the administration of arsenic in a still more outrageous manner than that just mentioned.

Applied, however, to the *sound* skin, arsenic has generally very little effect unless it be rubbed upon it, or be applied in the form of ointment, liniment, or paste. In the latter case, and even when used in the state of a fine powder, the application of arsenic has given rise, as Sir R. Christison has shown, to serious local and constitutional symptoms. The form of poisoning which is just now attracting so much attention is remarkable, and almost unique, from the fact of the poison being contained in an article which is used in every household, from the extent to which it was distributed, and the havoc it caused among the children on whom it had been applied. In 28 cases where the violet powder was used no less than 12 or 13 deaths resulted. In most of the cases under consideration the victims were young infants, in whom the delicacy of the skin and the activity of the function of absorption at that period of existence would doubtless aid the operation of the powder, were there no other circumstance calculated to make the use of such a powder extremely perilous. But in many cases, probably, the skin was more or less abraded, or, at all events, not in a healthy condition. Indeed, one of the witnesses stated that the skin of her infant's face was very red, and broke out all over the face and neck, "and the more the redness and soreness increased, the more the powder was used." As regards the symptoms, they were much the same as might have been expected from the application of an irritant like arsenic to the delicate and, perhaps, unhealthy skin of a young infant. Redness, pimples, blisters, sores, "whiteheads" or pustules, a black or bruised appearance of some parts of the body, were the chief external symptoms noticed by the mothers of the children. We have very little information with regard to the constitutional effects of the poison, and altogether this part of the evidence will not be complete until the medical witnesses have been examined.

Counter Prescribing and its Defenders.

As it is evident that the druggists of England hope to break down by force of money and legal delay the attempt which the Medical Defence Association is making to put a stop to the illegal and improper assumption of medical functions by members of the trade, we have to appeal to the profession to aid the Association to meet these tactics by the only means in which they can be met, *i.e.*, by contesting every effort of the druggists to sustain this abuse of their trade functions. At the annual meeting of the chemists and druggists' trades-union last week, it was decided (although the Union had £500 at its bankers) to raise a special fund of £2,000 to fight the medical profession. The speakers declared that "it was the unanimous desire of the trade to fight out the question of counter practice to the very end, even to the House of Lords if necessary, and this would entail a very heavy expenditure." This intention is quite natural, inasmuch as the trade has been making a very handsome income by assuming to do that which the law and common sense strictly forbid them to do, and which, with every respect to them, they are, as a whole, totally incompetent to do; and it is to be expected that they will not yield so profitable a part of their business without a violent struggle?

These gentlemen express unbounded confidence that the feeling of the public and of Parliament is all in their favour. Why then do they not spare their £2,000, and, instead of attempting to sustain their alleged rights by special pleading on a legal quibble, meet the question fairly and finally, by introducing a Bill into Parliament to assert their privilege to act as medical practitioners. They well know that such a bill would have no chance of ever getting a second reading, and they therefore feel that their whole dependence is on the possibility of lawyers differing as to the present law, and on the likelihood of their being able to protract the law proceedings, and mystify the judges until the Medical Defence Association surrenders in sheer weariness.

From the energy of its proceedings hitherto, we may be quite sure that the Association will do nothing of the sort if it is encouraged and supported by the profession. Surely, to put the matter on the lowest ground, it ought to be worth the while of the general practitioners in England to invest a few shillings each to defend themselves against the competition of some tens of thousands of druggists throughout the country who, if established in their illegal practice, will take tens of thousands of pounds each year out of the pockets of the general medical practitioners. Surely, from a public point of view, it is worth something to protect the uneducated masses from the therapeutic eccentricities of traders whose notion of doctoring is seldom confined to the conventional and usually inoffensive purge and cough bottle.

The Dublin Mortality and the Small-pox.

The bill of health of the city of Dublin for the week ending the 18th of May—the latest date for which the Registrar-General has a return—is a most alarming document. The death-rate has increased to 36·5 per 1,000 of the population, which is not much less than double that of the English and Scotch cities quoted, London being 20·1, Glasgow 22·9, and Edinburgh 17·8 The deaths for the week (221) re one more than one-half greater than those of the same week of the previous ten years (147). From these 74 extra deaths, may be deducted 14 caused by the Hamond Lane boiler explosion, but the remaining 60 lives were lost over and above the usual mortality of this, one of the most unhealthy cities in the United Kingdom. The small-pox epidemic cost 21 lives, but even deducting these, the death-rate is still above the average, and monstrously above the rate for large cities similarly situated. The deaths from small-pox for the last weeks were respectively 15, 9, 21, 17, 12, 21. The cases in hospital have increased from 254 to 270 within the week, and the new cases admitted to hospital (106) were 16 in excess of those admitted in the previous week. Under the auspices of the Public Health Committee of the Corporation, dirt and sanitary neglect continue to reign supreme.

In Belfast there was, within the week, one death from small-pox, 5 from fever, and 2 each from measles and diarrhœa. In Limerick there were 2 deaths from fever, and 1 from diarrhœa.

The Beginnings of Medical Men.

It is frequently remarked by those who, dipping no farther than the outer crust, form their views of the future medical man from the boisterousness of those medical students who occasionally make themselves unfortunately prominent in our police courts, that the initiatory characters of such are not likely to develope into respectable practitioners. Sir James Paget has answered these opinions with statistics. At the distribution of prizes to the successful students in the medical department of King's College Hospital last week, Lord Carnarvon, in the course of his address, said he had asked himself the question whether those who had distinguished themselves that day were likely to follow up their work in after life. Upon that point Sir James Paget had referred him to statistics, which showed that out of 1,000 students 23 had achieved distinguished success, 69 had achieved what might be called considerable success, and 507 had achieved fair success. That he reckoned to be a larger proportion than any other of the higher professions could boast. The opinion of Sir James Paget in reference to the medical profession was that as a man began so he continued, and so he ended.

The New Journal "Brain."

No doubt one of the "current topics" of conversation among medical men will be the advent of a new quarterly journal devoted especially to the functions and diseases of the brain and nervous system. Judging from the first number, it bids fair to be a first-class periodical, the contributors to which are alone sufficient guarantee of the great value and originality of the articles it contains. Among these contributors we notice the names of Drs. Clifford Allbutt, McCall Anderson, Bastian, Lauder Brunton, Brudenell Carter, Lockhart Clarke, Klein, G. H. Lewes, Burdon Sanderson, and the editors, Drs. Bucknill, Crichton-Browne, Ferrier, and Hughlings-Jackson. The first number contains several good original articles, amongst which we specially mention those on

"Motor Feelings and the Muscular Sense," by G. H. Lewes; "On some Symptoms of Organic Brain Disease," by Dr. W. R. Gowers; and "On Brain Forcing" by Dr. T. Clifford Allbutt. There are also critical digests and notices of books, clinical cases, and abstracts from British and foreign journals. Some of these articles we shall notice more at length hereafter; in the meantime we may congratulate the editors on the promising character of this new undertaking.

Treatment of the Vomiting of Pregnancy.

THE vomiting of pregnancy is so often rebellious to treatment that any new remedy for this troublesome complaint cannot fail to arrest our attention. Two remedies have been recently vaunted in the pages of two American journals, one the bromide of potassium, the other ingluvin (*ventriculus callosus gallinaceus*). Dr. Samuel Pusey, of Washington (*Amer. Jour. of Med. Sci.*, Jan. 1878), administers in the form of enemata from thirty grains to a drachm of the bromide in beef-tea, every four hours, until the vomiting has ceased; and he says that this treatment has never failed in any case that has fallen under his observation. The use of this medicine in the vomiting of pregnancy was first tried by Dr. Girabetti, who gave it in increasing doses, beginning with 92 grains the first day, 120 the second, 150 the third, after which the doses were diminished. In another journal (*New York Med. Record*, quoted by the *Practitioner*) we read that Dr. Charles G. Frowert, of Philadelphia, has had a case of obstinate, vomiting in which, after the failure of other remedies, Warner's ingluvin proved very successful. Doses of 5 or 10 grains not appearing to have much effect, the quantity was increased to 15 grains, three times a day, or every three or four hours; the attacks were effectually controlled, the symptoms ceasing entirely in four or five days.

Treatment of Glandular Engorgements.

FOLLOWING the example of Nélaton, Dr. Quinart, a French surgeon, counsels the application of blisters not only on enlarged glands, but upon those in which pus has already formed, and he says that, by this method, he has succeeded in obtaining the resolution of inflamed glands which have already contained many ounces of pus. When the perforation of the skin is imminent, he punctures the tumour at its most depending part, and as soon as the pus has been discharged, he covers it with a blister which is extended to a margin beyond its limits. The next day the blistered surface is dressed with mercurial ointment, and a new blister is applied as soon as the first surface begins to dry up.

Reason v. Tradition in the Treatment of Certain Injuries to the Wrist Joint.

DR. L. S. PILCHER, M.D., in a communication to the Med. Soc., King's Co., America, considers that Colles fracture is caused by the action of the anterior ligaments, the fragment being torn off. It partakes more of the character of a sprain than of a fracture, and when reduced by proper manipulation requires no splints to keep the fragments in place; indeed, the splints are hurtful. Massage, pressure and motion are required after the first few days. The New York *Hospital Gazette* says this is an original paper, and except that some of the author's views are a little too exclusive, it is sound. Probably nothing has been contributed which throws so much light upon this obscure subject since Vollmier and Robert Smith wrote.

The Tincture of Ergot in Hypodermic Injections.

M. SUTON, in a paper read before the Société Médicale de Reims, advocates the use of a tincture of ergot for hypodermic administration. We have, he says, on another occasion, discussed the question as to the best preparation of ergot for the above purpose, and we have given the preference to the normal alcoholic tincture, rejecting the solutions of the substances called *ergotine*, *ergotinine*, &c. This tincture is a reddish liquid, limpid, and of a not disagreeable odour. Its contact with the tissues causes no inconvenience, and it is not more painful than ether, chloroform, or chloral. The pain felt at first is immediately followed by a sensation of heat, which, in its turn, soon passes off. Provided the injection is carried sufficiently deeply beneath the skin of a part abounding in cellular tissue, there is no fear of sloughing, or of an abscess forming. The dose of the tincture varies from fifty centigrammes, or a gramme, to two or three grammes. The average quantity required is a gramme, representing twenty centigrammes of powdered ergot. Not to mention the application of this tincture to the treatment of puerperal and other hæmorrhages, all the therapeutical and physiological properties of ergot are secured by a preparation which, unlike the *soi-disant* ergotine, contains all the active principles of the drug. There is, says M. Luton, no occasion to show that ergot acts chiefly upon the organic muscular fibre of the abdominal viscera—the uterus, bladder, rectum, &c. We wish to show the special application of that drug to the treatment of retention of urine of a functional or paralytic nature. The efficacy of ergot in such cases was strikingly shown by an observation recorded in *Le Mouvement Médical*, for while that drug was being administered in a bad case of typhoid fever, with the view of arresting an intestinal hæmorrhage, accompanied with distressing meteorism, the bladder, which was paralysed and very much distended, was, at the same time, freely emptied. It is not in one case merely, but in several cases, that this treatment has been successful, the urine being generally passed about half-an-hour after the injection. It is particularly serviceable in retention of urine of a simple paralytic nature, and especially in cases of adynamia, coma, profound prostration, &c.

Pharmaceutic Ignorance.

AN American court, recently disposed of a suit for damages instituted by a lady against a druggist. It was proven that the lady sent a small boy to the apothecary's for some arsenic, which she had been in the habit of taking for neuralgia. Soon after swallowing the usual dose of the material sent her by the druggist, the plaintiff became seriously ill, and was near dying in convulsions. She swore that these symptoms have since recurred on several

occasions. The medicine was proved to be strychnia instead of arsenic. A verdict of damages awarded the plaintiff the amount of 1,050 dollars. Such, says the *Chicago Journal*, is the just recompense for the ignorance of a man who, in order to sell liquors, pursued the business of a druggist, and who, when upon the witness stand, *could not tell how many ounces made a pound of apothecaries' weight.*

Treatment of Headache.

Among the remedies recently recommended by Dr. Eugène Dupuy, of New York, for that form of headache called migraine, is irritation of the peripheral nerves by throwing a jet of carbonic acid gas against the nasal mucous membrane. He also recommends the bromide of potassium added to the potion of Riverius, which consists of an effervescing mixture of citric acid and the bicarbonate of potash, and taken so as to allow the effervescence to take place in the stomach. "The mode in which these means act is the removal of irritation from the tract of the middle encephalon, where the roots of the fifth nerve have their origin." We are, however, inclined to doubt both the efficacy of the remedy and its supposed *modus operandi*. Arsenic is another remedy in which Dr. Dupuy places much confidence. Given to such an extent as to produce slight œdema of the lower eyelids, it will sometimes remove the attack for a long time. Cannabis indica has also "a strong curative effect" upon this form of headache.

Narcotics in the Treatment of the Insane.

In the last annual report of the Stirling District Lunacy Board Dr. James Maclaren says that in the individual cases where any mental excitement occurred little reliance was placed on narcotics or other so-called soothing medicines. "It has struck me," he adds, "very forcibly that in attacks of acute mania the recovery has been more rapid and the intellect much clearer and brighter where these have been avoided. They undoubtedly may produce temporary quiet, but the condition in many cases seems rather one of stupefaction than anything else. The dull, hazy, muddled condition in which large doses of chloral and other similar drugs leave a patient is certainly often not a very hopeful state as regards the ultimate recovery of nervous tone; in fact, it has often seemed to me that the combined effect of acute excitement and large doses of narcotic medicines has been something bearing a strong resemblance to a complete wreck. Tonics have been very largely had recourse to, and special attention has been paid to the proper dieting of recent cases." We need scarcely observe that this is not the general opinion of the profession with regard to the value of narcotics in the treatment of certain cases of insanity. Many eminent authorities, both living and dead, might be quoted in favour of the use of morphia, chloral, or bromide of potassium in some cases where want of sleep and excitement are prominent symptoms. Nevertheless, such experience and such an opinion as that we have just cited will act as a wholesome check to a practice which is no doubt in many instances abused or carried to excess. It is, moreover, by occasionally withholding certain reputed remedies at times when their administration is considered a matter of course, that we can judge whether their therapeutical value is as great as is generally supposed. For this reason we should be glad to hear from Dr. Maclaren of his further and more detailed experience on this question of the utility of narcotics in the treatment of those symptoms of insanity for which they are so commonly given.

A Novel Literary Distinction.

According to Lieutenant de Corbigny, literary men in Annam are known by the dimensions of their nails, which sometimes attain a length of twenty-five centimetres. The nail of one finger, however, is cut short, to enable its possessor to scratch himself—a laborious undertaking in all classes of that country.

The mortality in most of the large cities of the United Kingdom last week was exceedingly low, Dublin excepted, where the death-rate reached the very high figure of 37 per 1,000 of the population; whilst London returned but 20; Edinburgh, 18; and Glasgow, 23 per 1,000.

Dr. Burdon Sanderson will be the Harveian orator this year. The oration will be delivered at five o'clock on Wednesday, June 26th, at the Royal College of Physicians of London.

LITERARY NOTES AND GOSSIP.

An institution has just been started at 26 Suffolk Street, Pall Mall, called the London Athenæum, as a central general reference library for professional men. Such an institution will doubtless be much appreciated by country practitioners, as being a *rendezvous* for meeting friends, receiving letters, &c., when visiting the metropolis. There is no entrance fee for the first 500 members, the annual subscription being one guinea for country members, two guineas for town members.

* * *

It is not often that a purely philosophical work arrives at the distinction of an eighth edition. Such, however, is the case with Hartmann's "Philosophie des Unbewussten" published during the past few days.

* * *

We understand that the second volume of Roscoe and Schorlemmer's "Chemistry," and the second edition of Dr. Semple's "Aids to Chemistry" are in the press. Dr. Alleyne Nicholson's "Manual of Zoology" has just gone into a fifth edition. The MS. of Dr. Morell Mackenzie's new work "On the Throat" is now in the printer's hands. A third edition of Dr. Prosser James's "Sore Throat," and a small brochure by Dr. Julius Pollock, "Notes on Rheumatism," have also been published during the past week.

* * *

The second thousand of Surgeon-General Gordon's little work "The Soldier's Manual of Sanitation" is announced. This little work will probably become—if it does not already occupy that position—the pocket text-book for officers and men of the regular and volunteer forces, on account of its practical and common-sense nature for prompt aid to the wounded pending the arrival of a medical attendant. The Government would do well to distribute this very freely throughout the regiments, and thus assist both the military surgeons, and the men themselves in the immediate care of the wounded.

* * *

Some very interesting experiments have been conducted at the Paris Academie des Sciences, during the past few days, by some literary and scientific celebrities, resulting in intelligible sounds being passed through a single-wire telephone, by a derivation of current from other systems through wet ground.

An interesting lecture "on the Chemical Aspects of Vegetable Physiology," at the last meeting of the Chemical Society, gave rise to an animated discussion on the evolution of oxygen, and the formation of starch grains. The conclusions of Liebig and Mulder were denied so far as relates to the formation of vegetable acids, and the composition and functions of chlorophyll left to future speculation as heretofore.

* * *

Messrs. F. W. Lowndes and A. Bernard, surgeons to the Liverpool Seamen's Dispensary, have issued a supplementary report which will be of special interest at the present moment, when opinions are so diverse of the Contagious Diseases Acts, and Parliament is engaged in a debate thereon. This supplementary report is published separately, as it was thought by the committee that the details with which it deals were not such as should be included in the general report which is circulated amongst the public. It being printed for private circulation, those of our readers who feel sufficiently interested in the subject will probably be able to get a copy from either of the above-named gentlemen.

Correspondence.

ON BLOOD-LETTING AS A THERAPEUTIC.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—Your article of May 15th upon the value of blood-letting in an emergency, so full of anxiety to all concerned in puerperal convulsions, is most interesting to the *accoucheur*. But next to him it has a mission to the physician and the surgeon also, as it tends to open the way to long-neglected and almost forgotten paths in the practice of their profession.

Thirty years ago—if no later—a *grinder* would have considered his pupil to have taken a good edge, and to be in a fair way of cutting through the examiners to the profession, if he could, to the question of how to treat most diseases, common and uncommon, promptly reply, *Bleed, blister, and give calomel!* The examiners also satisfied as to his competency when *ground* so, "let loose" the candidate; but as soon as this occurred, he, wiser than both grinder and examiners, turned his back upon his friends, and if he ever mentioned those at all, it was only to laugh at them. No doubt he had his reasons for this, especially if he was naturally a sharp fellow, as a remedy which cures everything is often found upon trial to be not much of a cure for anything. Besides, having seen—probably under his teachers—the "bleed, blister, and calomel" method carried to a mischievous extreme, he therefore, with an excess of caution in his wisdom, resolved to have none of it. Novelty, too, which fashions everything—our garments, our food, our pleasures, and wherefore not our physic?—had moreover something to say to it, and thus has arisen a new order of practitioners to whom the very name of bleeding is an abomination.

Deeming myself not an extreme man—professionally, at least—I consider the modern school to be as faulty in principle as its predecessors were, whose one aim appeared to be to outrun even the great Sangrado himself; and with your permission I now proceed to give reasons for my belief, but lest they be insufficient, I will try to mix them well with facts. ("Masters!" says J. J. R., "but little talk; give your lessons in examples, and be ye sure of their effects.")

While a student, not wishing to be puzzled by very fine points of physiology, I always sought to follow the teachings of moderate masters, and when those told me that in such diseases as sthenic pneumonia I *might* bleed, but, at any rate, I *must* leech, I was satisfied that this teaching came to me fortified by experience. In like manner, when they assured me that in such diseases as phrenitis, puerperal convulsions, pleuritis, iritis, and sometimes peritonitis, I *must* bleed, I was also satisfied and resolved to make a mental note of this, so that it would regulate my future practice. In a practice, therefore, extending over some ten years, I have deemed it necessary, in view of my instructions, to bleed from the arm about two dozen times, and to leech fully and frequently, and in no case but two was this venesection followed but by recoveries the most successful; and the same assurance has reference to the much more frequent leeching. The successful cases of bleeding were pneumonia, pleurisy, peritonitis, puerperal convulsions—the latter occurring to a plethoric lady approaching the age of forty, two days after a "hard" delivery, and whose liver and kidneys had been congested for some time before parturition—and even acute and subacute rheumatism. The two unsuccessful cases were apoplexy and pleuritis, with convulsions. In the former I was not permitted by the friends to bleed—according to my judgment—enough, and was otherwise hampered in the treatment. In the latter the bleeding was done *too late*, I not being within reach of the patient for nearly twenty hours after the seizure. This being my experience of bleeding, I have now to speak of leeching, which I have found, and still find, to be most satisfactory also. It would be wearisome to enter into a detail of the latter, as certainly no month elapses without my having to prescribe it for some one; but I may mention the kind of cases in which I do prescribe it. These are pneumonia, rheumatism—articular and muscular—hepatitis, nephritis—idiopathic, or from scarlet fever—peritonitis, orchitis, severe sprains, and even at times in such a case as compound fracture. In all the above, benefits the most marked followed it, and in some the single word marvellous would be the one word most appropriate. Nor am I deterred from resorting to it by the cry now in fashion that in this adynamic age people want blood pumped into them instead of being deprived of it. I have, in a case of puerperal peritonitis in a weakly girl, applied twelve, and the next day following, other six leeches—eighteen in all—and followed this treatment by a fly blister, nine inches by six, while I gave calomel, opium, and quinine, and claret intermittingly, and yet the patient did not die, as some would express it. In a case of rheumatic synovitis of the knee-joint, when a delicate female enjoyed not a minute's rest day or night for six or seven weeks, I have, as soon as called in, applied eighteen leeches, six every alternate day, with other active treatment, and in less than three weeks the patient was able to walk about, although she was so weak when leeched that she fainted at the third leeching. And equally successful have I found leeching in nephritis, after that most debilitating disease, scarlatina.

While such have been my observations upon bleeding and leeching, I have not failed also to observe cases and their termination in which one or other of them, or both, were omitted. I have seen scores of children die from dropsy after scarlet fever, who, in my opinion, might be saved by timely leeching. I have seen pleuritis followed by empyema, and the abscess at last bursting externally, so that there could be no mistake about the case then, when neither bleeding nor leeching had been ever thought of. I have seen rheumatic synovitis of knee-joint end in white swelling and amputation at last, for the want of leeching; and in a similar case which had been freely leeched *too late*. I have seen anchylosis end it, so that, to sum up, this cry of want of blood, is, in our day, a most idle and vicious one.

A doctor, more than any other man, should be a student of Nature as well as human nature, and if he would note carefully the cases in which a timely attack of epistaxis, hæmatemesis, melæna, or hæmorrhagia, especially in people turned forty years, and of full habit, has saved a patient's life from apoplexy or paralysis, when the liver had been allowed to get disordered and blocked up, this outcry against bleeding would not ride on him.

I am, sir,

Respectfully yours,

J. O'Flanagan, L.R.C.P. Edin.

Houghton-le-Spring, Durham.

ANNUAL MEETING OF ROYAL COLLEGE OF SURGEONS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—There are many friends of Mr. Wm. Adams who would be glad to vote for him at the Fellows' annual meeting at the College on the 4th July next, and he has been urged to offer himself as a candidate, but as Mr. Gay is a friend and colleague, Mr. Adams is afraid that his candidature would imperil the chance of Mr. Gay. Mr. Adams has therefore very generously declined to be nominated, and he hopes that Mr. Gay may be elected to a seat in the Council, for which he is so well qualified.

I am, your obedient servant,

Henry Harris.

Redruth, 21st May, 1878.

UNION HOSPITALS AND COUNTY INFIRMARIES.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Dr. Thompson reminds me strongly of a certain small English statesman whom *Punch* described as first writing something on a wall and then running away in terror from the consequences of his own act. Dr. Thompson informs your readers that he does not consider it necessary to enter into further discussion anent his reflections on union hospitals, but with all respect to that gentleman he cannot be permitted to execute his graceful retreat without further molestation from the enemy. Compilers of hospital reports must be prepared for the same measure as that accorded to every other writer, and they consequently must be prepared to have the plain English meaning put in plain English words. You, Mr. Editor, with a chivalrous boldness which I had thought quite extinct in these degenerate days, rushed to the defence of your friend in your issue of April the 24th. You stated, and Dr. Thompson, in his last letter, declares your opinions are his, "that no reflections were intended to be made on the skill of the officers of workhouse hospitals, but that the disadvantages under which their patients labour in the scientific treatment of their medical, and especially of their surgical diseases, arose from the fact that grave surgical cases, instead of being aggregated in the small compass of a single hospital, are interspersed up and down in half a dozen workhouse hospitals among the mass of workhouse sick." Now, Mr. Editor, I have no wish to be hard, nor does indeed the matter call for it, on Dr. Thompson, who is, he will permit me to say, a credit to his institution; but as I am accused of jumping to hasty conclusions without making myself acquainted with facts, exhibiting an unbecoming professional jealousy, thereby displaying small-mindedness, &c., I must be allowed again to quote the exact words used by Dr. Thompson. It is impossible to deny that they convey the most obvious insinuations against the skill of workhouse surgeons. Here are the words:—"I briefly pointed out the disadvantages the patients laboured under as compared with county infirmaries in the scientific treatment of medical, especially surgical diseases. I endeavoured to point out the necessity for a central hospital in each county for treatment of severe (reader, mark the words!) medical and surgical cases, and I drew attention to the irreparable loss the medical profession would suffer by the general closure of county infirmaries." He states further down that he was obliged to refuse admission to fifty applicants who were either incurable or unsuitable—trivial cases, of course—for admission to the worknouse. Now, sir, there is but one meaning to be put on all this, and it is the meaning that I and not you have put on it. I am glad that in his last letter Dr. Thompson has done justice to his own high character by gracefully withdrawing all aspersions on the skill of workhouse officers. And now, Mr. Editor, when your ideas as to the disadvantages patients labour under in workhouse hospitals are confined to the fact that grave surgical cases are in them diffused mid a crowd of lighter ones not concentrated in one seething mass, allow me to remind you what perhaps before you had not thought on, that this very dispersion is the one thing called for by the universal scientific professional opinion of the day.

Truly yours,
THOMAS LAFFAN.

[We do not think it necessary to notice Dr. Laffan's communication further than to say that he entirely misconstrues what both we and Dr. Thompson did say.—ED. M. P. & C.]

Medico-Parliamentary

CONTAGIOUS DISEASES ACT REPEAL BILL.

IN the House of Commons, on Wednesday last, Sir H. JOHNSTONE proceeded to move the second reading of the Bill, submitting that the returns which had been laid before Parliament afforded a convincing proof that the continuance of the Act was not justified by the circumstances of the case. The hon. member was entering into a variety of details in illustration of his argument, when

Mr. MOORE moved that the ladies' gallery be cleared, this was put to the House, and lost, and

Sir H. JOHNSTONE resumed his speech, remarking that on the part of many of the towns of this kingdom, which protested against these Acts, he was bound to say that the very construction of them was a direct interference with the powers and privileges of municipal authorities. The idea of making policemen the special guardians of public morality was in itself so absurd that he would not waste time in dwelling on that topic. If there was one woman who three and twenty years ago made great personal sacrifices for the good of the soldiers of England, that woman was Florence Nightingale, and she had been the first to sign the petition he had presented that day, feeling sure that a system of Government regulation and examination was contrary, not only to the rights of women, but to the general liberty of the State. He was convinced that year after year would bring conviction to the minds of those still undecided that it was impossible to maintain these Acts in the face of the public feeling of the country, which, whether rightly or wrongly, was persuaded that they had not done any great amount of good, while they had outraged the public feeling of this country to a most terrible extent.

The Right Hon. W. H. SMITH, who rose at twenty-five minutes to six o'clock, expressed his great regret that the hon. baronet should have thought it necessary to bring this most painful question before the House. It was one of the most painful subjects that could be debated in the British House of Commons. He was very far from calling in question the motives of the hon. baronet, and of those who took an interest in the subject, but he could not help feeling that they took but a very partial view of it, and one which it was not unnatural men should take who were not able themselves carefully and thoroughly to study it. From experience and examination he had come to the conclusion that these Acts were beneficial to the public morality, to the persons who were principally affected by them, and to the State.

It was now a quarter to six o'clock, and the debate, in accordance with the standing order of the House was adjourned.

THE MEDICAL ACT AMENDMENT BILL.

In the House of Lords on Friday last, the Duke of RICHMOND and GORDON said that in consequence of the amendments he found himself compelled to insert in this Bill he should not ask their lordships to go into Committee on the Bill that night, but to allow him to commit the Bill *pro forma*, that all his amendments might be reprinted, so as to enable their lordships to discuss them with greater convenience. When he introduced the Bill he gave a considerable period of time between the second reading and going into Committee, in order that the Bill, affecting as it did the public and the medical profession in a great degree, they might have ample time to consider its provisions, and that he might have the advantage of ascertaining the opinions of those interested in the subject, which might enable him to put the Bill in as satisfactory a state as possible. That had been responded to. Various deputations had waited on him on the subject, and he had received numerous letters from m dical men from all parts of the country, and also of the metropolis, in reference to the provisions of the measure. He stated when he introduced the Bill that the best mode of dealing with the subject would be by establishing a uniform minimum standard of examination. No doubt that would be the best mode of securing the best qualified persons to become medical practitioners, to be arrived at by a conjoint board of the three Kingdoms, but that instead of its being permissive it was proposed that it should be made a compulsory board, formed of all the medical corporations of the three countries, leaving it to the Universities to come into the arrangement if they thought fit to do so. The communications he had received since showed that it met with the general approval of the profession of the three countries, and he had reluctantly come to the conclusion that he must ask their Lordships to allow him to amend the Bill so as to make the conjoint board a compulsory one. He proposed to amend the Bill in that respect, and therefore he asked their Lordships to allow the Bill to pass through Committee *pro forma*, and to postpone any discussion until some day next week.

Viscount POWERSCOURT said he was glad to hear that the noble Duke had consented to the change.

The Marquis of RIPON thanked the noble Duke for the change he proposed to make in the measure. It was most desirable in the interest of the public.

Earl GRANVILLE said that he congratulated the noble Duke

on the change he had made in the Bill, and said that he had no doubt it would be a great benefit to the medical profession and the public at large.

The Bill then passed through Committee *pro forma*.

LIMERICK LUNATIC ASYLUM.

In the House of Commons on Friday last Mr. Butt called attention to the order in Council removing the Mayor of Limerick from the Governorship of the Lunatic Asylum, Limerick; and had given notice of his intention to move, "That, in the opinion of this House, it is expedient in orders in Council appointing governors of lunatic asylums to observe the old practice of appointing the mayors of cities." He said he did not consider the subject one on which it would be necessary to put the House to the trouble of a division, even if the rules would have permitted him. It was, however, one in which a great deal of interest was taken in the city he had the honour to represent. It was an illustration of a form of government too common in Ireland. It related to the removal of the mayor and certain other persons, in the most unaccountable and arbitrary manner, from the places they had long occupied on the Board of Governors of the Limerick Lunatic Asylum. These asylums imposed heavy taxation on Ireland, and yet in their management there was no single particle of representation of the ratepayers.

Mr. J. LOWTHER said that the Government had no desire to throw difficulties in the way of municipal institutions, and they fully recognised the importance of appointing proper persons as governors of lunatic asylums. He should have been content to allow the matter to rest until it could be brought forward in a proper manner; and he should take an early opportunity of conferring with the Lord-Lieutenant on the subject. He could assure the hon. and learned gentleman that the Government had every desire to remove any grievance which might be found to exist.

After a few words from Mr. O'SHAUGHNESSY and Mr. MURPHY, the subject dropped.

THE CASE OF MR. DODWELL.

In reply to Dr. Kenealy, Mr. CROSS said that Broadmoor Asylum, so far as insane male persons were concerned, was filled only with those who had been acquitted on the ground of insanity; that was the present rule. When this gentleman was found to be insane by the verdict of his countrymen (for shooting at the Master of the Rolls) he was sent in the ordinary course to Broadmoor. As he stated some little time ago, letters were received at the Home Office from Dr. Forbes Winslow and Dr. Winn, and they were sent on the 15th of April to the authorities at Broadmoor, with the intimation that when those authorities were able to report that it would be consistent with the safety of the public and of Mr. Dodwell himself, either absolutely or conditionally, that he should be at large, his case would then be considered, and not till then. No report had yet been received.

Obituary.

Dr. JEPHSON, Leamington.

AT the ripe age of 80 years has passed away, in the person of Dr. Henry Jephson, a physician who at one period may be said to have had the largest and most lucrative practice in the United Kingdom. Deceased was born at Mansfield, Nottinghamshire, in 1798, and early in life showed great aptitude for scientific pursuits, especially in experimental chemistry. Once during his experiments he nearly lost his life by an explosion of fulminate, which carried away two of his fingers. After passing, he went to Leamington as an assistant to a practitioner of some reputation in that town, to whose practice he afterwards succeeded. He subsequently went to Glasgow and obtained the M.D. degree of that University, returning to Leamington at the urgent request of his patients and friends, where he practised for twenty years as consulting physicion. So great was his popularity that it is said patients came from all parts of the country, and even from the colonies, for his opinion, until his professional income was swelled to over £20,000 per annum. But this constant and unceasing wear of body and mind eventuated in loss of health, and ultimate blindness, necessitating his retirement into private life in 1848. With his wealth he was mosi generous, and apart from his professional acquaintances, he had a host of sincere and admiring friends. Dr. Quain, of London, and Dr. Heslop, of Birmingham, were in attendance upon him in his last days, and everything that skill could devise was therefore at hand, but Nature was exhausted, and he gradually and painlessly sank a few days ago, leaving behind him a memory which will be long cherished by all who knew him.

Dr. ALLISON, Barrow-in-Furness.

AN old and much respected inhabitant of Barrow-in-Furness has just passed away, at the age of 60, in the person of Dr. Joseph Allison. In early life deceased was in medical charge of Government troops viâ the Cape to India. He went to reside in Barrow 23 years ago, and was for many years the only medical man in that town, where his skill and kindly disposition were much appreciated, and he was elected to all the local and many neighbouring clubs. He was also one of the honorary surgeons to the North Lonsdale Hospital. He was one of the oldest members of the local volunteer force, and joined the ranks as a private at the first swearing in. Subsequently, on the occasion of an accident occurring during a review at Holker, by which a volunteer's finger was shot off, his services were fortunately available, and Lord Hartington, the then colonel, requested him to take a commission as surgeon to the battalion. This he held to the time of his death, having attained to the grade of surgeon-major. He was also a member of the Town Council, and held the appointment of medical officer under the Corporation. For many months his friends have noticed his health failing, but he was slow to recognise it himself, and he continued his practice up to a few weeks before his death, the immediate cause of which was softening of the brain. His remains were followed to their resting-place by a numerous gathering of volunteers, the leading gentry and tradesmen of this now populous town, who testified by their attendance and bearing the esteem in which deceased was held.

Medical News.

Royal College of Surgeons, of England.—The following gentlemen having passed the required examination, received the diploma of M.R.C.S. of the College at meetings of the Court of Examiners on May 21st, 22nd:—H. Edward Ambler, Hemel Hempsted; J. Henry Barnard, Fulham; John Bibby, Preston; W. Price Biden, Peckham; J. Maunday Biggs, Dallington, Sussex; Ernest Blacker, L.R.C.P. Edin., Bath; E. Collins Bousfield, Bedford; W. George Clements, Rochester; W. Henry Copley, Melton Mowbray; F. Henry Corbyn, L.R.C.P. Edin., Cheltenham; F. Samuel Cowan, Bath; H. Edward Davies, Llanddulas; George Davis, L.R.C.P. Lond., Blackheath; D. Henry Dowsley, M.D., Clinton, Canada West; E. Napoleon Drought, Winchmore Hill; A. Samuel Faulkner, Liverpool; G. H. William Flower, Stafford, Dorset; F. Nalder French, Over, Cheshire; L. Henry Fuller, Bath; H. John Gover, M.B. Clapham; W. Wollaston Groome, Monks Soham; W. Frederic Haslam, Reading; C. Henry Hough, Cambridge; G. Henry Jackson, L.R.C.P. Edin., Liverpool; G. Frederick, Jackman, Beaulieu, Southampton; W. Thomas Jackman, Stoke-Newington Road; R. Dennett Jones, Conway, North Wales; G. Alexander Macdonald, Hull; G. Thomas M'Keough, M.D., Chatham, Canada; A. Charles Morton, L.S.A., Aylsham; A. Joshua Newman, L.S.A., Watton, Herts; T. Henry Parke, Tideswell; J. Henry Pettinger, Manchester; W. Smith Porter, Sheffield; J. James Powell, Weybridge; J. W. Leonard Russell, Sheffield; C. Guthrie Stein, Cape Town; H. Ogilvy Stuart, L.S.A., Woolwich; W. Henry Walter, Sydenham; H. Langley Webb, L.S.A., Cheadle; Dawson Williams, Burnby, near York.

East London Hospital for Children.—The annual festival of this institution was held on Wednesday evening last in a large handsome tent erected for the occasion at the back of the hospital. From the last annual report it appears that the total number of patients treated during the financial year of the hospital, viz., from the 1st May, 1877, to the 30th April, 1878, including new out-patients, in-patients, and casualty cases was 7,463; and the number of attendances of out-patients and casualty cases, old and new, amounted to 23,793. Of the 7,463 patients treated within the year, 6,230 were new

out-patients, 588 were new casualty cases, and 645 were in-patients. After the usual loyal and patriotic toasts were duly honoured, the Right Hon. W. E. Gladstone, chairman, in rising to propose the toast of the evening, "Success to the East London Hospital for Children," received quite an ovation from the assembled guests. In a speech of nearly an hour's duration he dwelt upon the beginnings of the institution by Dr. Heckford, who, sacrificing personal ease, society, and all his private means to start a small hospital for children in the midst of that dense population at the East End, died just as his labours and anxieties were beginning to bear fruit. He passed on to notice the inestimable value the hospital had become in the hands of an able staff, paying, at the same time, a flattering eulogium to the medical profession, which was ever foremost in the relief of suffering humanity; and concluded by an eloquent appeal for funds. Mr. Norris, the treasurer, gave an account of his stewardship, and in an eloquent and impressive speech dwelt upon the claims such an institution had upon the west, as well as the east, of London, paying, at the same time, a well-merited tribute to Mr. and Mrs. Gladstone for their presence, and for the assistance Mrs. Gladstone afforded in taking their little convalescents into her Home at Woodford. Dr. Andrew Clark, in replying to the toast of the visitors, said, as they had inflicted upon him an after-dinner speech, he would retaliate with his private opinion of their chairman. He said that ever since it was his good fortune to become acquainted with that illustrious statesman he had never met him without extreme pleasure, and never parted from him without having learned much. Whatever might be their opinions politically, there could be but one entertained of Mr. Gladstone in his honesty of purpose, in the courage of his opinions, in the sacrifice of popularity for the sake of those opinions, and his readiness at all times to give his time and great talents for the welfare of the poor. Even if he had not the honour of a personal acquaintance, he would rejoice that he had lived to listen to such a profound speech on behalf of the suffering poor. Dr. Clark then passed a high compliment on Mr. Ashton Warner, the indefatigable secretary, to whose labours the hospital owes so much of its success. It was impossible, he said, to come in contact with zealous men like Mr. Warner without feeling that their zeal was infectious, and he hoped to carry away with him a portion of the zeal which seemed to characterise the whole of the staff. Mr. Arthur Cæsar, F.R.C.S., responded on behalf of the medical staff, and Mr. Warner announced subscriptions to the amount of £1,160.

Central London Throat and Ear Hospital.—On Wednesday evening last the annual ball in aid of this institution was held at Willis's Rooms, and proved a great success, both artistically and financially. Although fancy dress was not imperative, the licence to appear in evening dress was not extensively availed of, most of the gentlemen wearing either uniform or some costume. By 11 o'clock the rooms had become tolerably full. About 400 guests were present during the night, dancing being kept up till about four in the morning.

University College Hospital.—The annual dinner of this institution was held last week under the chairmanship of Mr. J. Eric Erichson, F.R.C.S., consulting surgeon to the hospital. In asking his hearers to drink the toast of "Prosperity to the Hospital" the chairman said at no period in its history had it stood more in need of the support of its friends and the public. The number of persons relieved by an hospital was not always a criterion of its value, as it might be stated that University Hospital in the last year, with its 2,131 in-patients, showed a percentage of 13·3 per bed, as against 9·2 of the whole unendowed hospitals of the metropolis. This was an evidence of remarkable medical and surgical activity. The secretary, at the close of the evening, read a list of subscriptions amounting to nearly £900.

Royal Hospital for Incurables.—The twenty-first anniversary dinner in aid of the funds of this institution took place last week under the chairmanship of Mr. R. N. Fowler, presiding. The number of inmates of the hospital are at present 187, whilst the society contributes to the support of no less than 389 individuals, regarded as pensioners, each of whom receives £20 a year, and these recipients are not confined to the metropolis, but are scattered over the United Kingdom. The chairman, in proposing the toast of the evening, pointed out this was a class of disease the end of which was not speedy death, and it was only reasonable to expect that each pensioner would remain upon their books for an average of twenty years. During the evening the Secretary read out the list of subscriptions, which amounted to £2,500.

NOTICES TO CORRESPONDENTS.

MEDICAL BENEVOLENT FUND OF IRELAND.—This Society will hold its thirty-sixth annual meeting on Monday next at 4 p.m., at the King and Queen's College of Physicians. Dr. Gordon, President of the College, will occupy the chair.

ERRATUM.—In the annotation headed "Morphine Mydriasis," in our last, "the sub-maxillary band" should read *gland*.

DR. OFFENBERG, Prussia.—Our Reports on "Rabies or Hydrophobia" were republished in book form about a month since. It forms a crown 8vo volume of 286 pages, and is published at 5s. by Messrs. Baillière, Tindall, & Cox.

PROF. BISCHOF.—Your letter, in reply to one in our last, came to hand as we were going to press. It will appear next week.

DR. P.—Your personal interest in the establishment is not a sufficient inducement for us to insert an article editorially which few of our readers would care to read. It is plainly an advertisement, and as such only can be inserted in our columns.

OBSTETRICAL SOCIETY OF LONDON.—Wednesday, June 5, at 8 p.m., Specimens: Extra-Uterine Fœtation, by Dr. Hayes; Hand-behind-Head Presentation, by Dr. Bryden; Drawings of a Living Double Monster, by Dr. Wiltshire. Papers: Dr. Aveling, "The Curves of the Forceps, their Origin and Use;" Dr. Matthews Duncan, "The Revolutions of the Fœtal Head in passing through a brim contracted in the Conjugate Diameter."

VACANCIES.

Limerick Union Workh ouse.—Resident Apothecary or Pharmaceutical Chemist. Salary, £100, with furnished apartments. Election, June 5.

London Fever Hospital.—Resident Medical Officer. Salary, £200 per annum. Applications to the Secretary on or before June 10.

Radcliffe Infirmary, Oxford.—Surgeon on the Staff. Testimonials, &c., to the Secretary on or before June 5.

Somerset County Lunatic Asylum.—Assistant Medical Officer. Salary commencing at £120, with board. Must have double qualification. Applications to the Medical Superintendent at the Asylum, Wells.

Southam Union.—Medical Officer. Salary, £40, with fees extra. Applications to the Clerk of the Board, Union Offices, Southam Warwick.

Tralee Union, Brosna Dispensary.—Two Medical Officers. Salaries, one at £60, and one at £90. Election, May 30.

Limerick Union Workhouse.—Resident Medical Officer. Salary, £200, with furnished apartments, &c. Election, June 5.

APPOINTMENTS.

BRIGHAM, H. G., L.R.C.P.Ed., M.R.C.S.E., Resident Medical Officer to the Royal Pimlico Dispensary.

CONNOLLY, W., L.R.C.S.I., Visiting Physician to the Waterford District Lunatic Asylum.

DREWITT, F. G. D., M.R.C.S., House Physician to St. George's Hospital.

HARDIE, D., M.B., C.M., Assistant Medical Officer to the Inverness District Lunatic Asylum.

HUGHES, J. R., M.D., M.R.C.S.E., Medical Officer of Health for the Denbigh Urban Sanitary District.

JONES, R., M.R.C.S.E., Certifying Factory Surgeon for Flint.

PARKER, R., L.A.H.D., Apothecary and Registrar to the County Infirmary, Roscommon.

TWEEDY, J., L.R.C.P.L., F.R.C.S.E., Ophthalmic Surgeon to the Great Northern Hospital.

ARMY MEDICAL DEPARTMENT.—Surgeon-Major A. Thomson, M.D., from half-pay to be Surgeon-Major; Surgeon A. P. Green resigns his commission.

Births.

DUFFEY.—May 23, at 30 Fitzwilliam Place, the wife of G. F. Duffey, M.D, of a daughter.

JEFFERSON.—May 19, at Lisburn, the wife of Dr. Jefferson, of a daughter.

MAPOTHER.—May 17, at 6 Merrion Square, Dublin, the wife of E. D. Mapother, M.D., of a daughter.

Marriage.

BUSH—POLE.—May 22, at St. Leonard's Church, Streatham, R. Hake Bush M.D., to Emily, eldest surviving daughter of Sir Wm. E. Pole, Bart., of Shute, Devon.

Deaths.

ATKINSON.—On May 11, at Sunniside, Sunderland, George Atkinson L.S.A.L., aged 67.

EALES.—On May 17, at Camden Road, William Penn Hele Eales, M.R.C.S.E., aged 68.

HAINES.—On May 9, at Littleworth, Gloucestershire, William John Haines, M.R.C.S.E., aged 22.

JACKSON.—On May 21, at his residence, Wallgate, Wigan, Lancashire, John Jackson, L.R.C.P.Ed., &c., aged 36.

MILLER.—On May 8, at the Lunatic Asylum, Powick, Reuben Zaccheus Miller, M.R.C.S.E., aged 40.

RUTTLEDGE.—On May 5, at Salonica, of typhoid, T. E. Ruttledge, of Ingatestone, Essex.

SCAIFE.—On May 19, at Sydenham House, Low Harrogate, Christopher Scaife, M.R.C.S.E, aged 58.

VICKERS.—On May 3, at Holywell, Flintshire, Thomas Vickers, M.R.C.S.E., aged 72.

WHICHER.—On May 21, at the Royal Naval Hospital, Malta, James Whicher, M.D., Deputy Inspector-General of Hospitals, aged 53.

WILLIAMS.—On May 21, at Redland, near Bristol, John Williams, F.R.C.S., Surgeon Major, Army.

IRISH POOR-LAW INTELLIGENCE.

DROGHEDA UNION.

PAYMENT TO TEMPORARY MEDICAL OFFICERS.

MR. M'KENNA mooved that in future in case of a medical officer requiring a substitute for more than one week, he should pay him himself and not levy the expense on the union. In moving the motion he had no animosity at all to any of the gentlemen who might be affected by it. It was their business to see that when they appointed doctors they do the duty they are appointed for. He did not want to apply his remarks to any present cases at all, but in future they should adopt a different rule and prevent an abuse in the way in which they allowed matters to be conducted.

Chairman—Is there any one to second it?

Mr. Everitt—I will second it, but with this limitation. I don't go to the sweeping extent of Mr. M'Kenna's resolution. I hold, and I am sure so do the greater number of the gentlemen I am addressing, that if a medical officer, or any other officer in our employment, happens to get incapacitated from duty while in the discharge of the duties of his office, every consideration is due to him, and we are not only bound, but will take care to see to his recovery. In legitimate cases of that sort I would spare no expenses, but in other cases certainly I fully agree with the spirit of the resolution.

Mr, Eagar referred to the instructions as to the duties of dispensary committees and the power given to medical officers to appoint substitutes.

Chairman—But there surely should be some limit as to the time that a substitute can act.

Mr. Mangen—According to Mr. Eagar's reading a substitute can be employed from one end of the year to another.

The motion, with Mr. Everitt's limitation, was adopted.

We may appropriately call the attention of the Drogheda Guardians and of Poor-Law Medical Officers to the letter of the Secretary of Council of the Irish Medical Association on the subject, which appeared in our supplement for May 15.

The Council direct attention to the fact that—in the terms of this Regulation—the duty of a dispensary medical officer, in case of his being "temporarily incapacitated by illness or other cause," is strictly confined, firstly, to his "immediately, if practicable, communicating with the chairman or honorary secretary," and "*recommending*" a duly qualified *locum tenens*. He is not authorised to appoint his substitute, and the committee has full discretion to act upon his recommendation, or to disregard it if they see fit. He has not any authority whatsoever to make arrangements with the *locum tenens* as to his remuneration, nor would any promises made by him be in the least binding either on the committee or the board of guardians. He is simply directed to suggest to the committee the name of a medical man who possesses the qualifications required by the regulations, and in doing so he will, of course, act rightly in recommending a practitioner who can conveniently and effectually discharge the duties for the advantage of the sick poor.

On the other hand, the practitioner who acts as *locum tenens* should underitand that his doing so is irregular until he has had a definite appointment from the responsible officer of the dispensary committee, and that he has no claim whatever for remuneration except on a definite arrangement on the subject with such officer. He will, no doubt, in circumstances of urgency, act upon the request of the medical officer *ad interim*, until the secretary or chairman of the committee can be communicated with, but he will distinctly understand that by so doing he acquires no claim—noral or legal—upon the medical officer. He should remember also that if he omits to obtain, at the hands of the committee, or its responsible officer, a definite appointment and a definite understanding as to payment, he does so at his own risk, inasmuch as it is the regulation that the guardians "shall, subject to the approval of the Local Government Board, determine the amount of remuneration (*if any*) to be paid to the temporary substitute," and it is therefore quite open to the guardians (and boards have frequently availed themselves of the power) to refuse to pay anything for such services unless they have previously contracted with the *ocum tenens* for a suitable remuneration for his services.

We particularly ask the attention of Mr. M'Kenna and his brother guardians to the following observations:—

The council also desires to point out that the dispensary medical officer who complies strictly with the terms of the Regulations, as above referred to, is entitled as a matter of right to receive his salary during the continuance of his illness, and it is not within the power of the guardians to refuse payment, or to make any deduction from the amount, either for the remuneration of the *locum tenens*, or for any other purpose, unless a special arrangement to that effect shall have been previously made between them and the medical officer for that particular occasion.

It is not within the authority of a board of guardians, by any resolution made at the time or previously, to alter the provisions of the Regulations, or to create a rule having such effect; and in case of their refusal to pay the *locum tenens*, the dispensary medical officer is not bound in honour or in law to make good such payment, unless he has implied or expressed understanding with the *locum tenens* to that effect.

SEQUESTRATION OF DISPENSARY SALARY.

A LETTER was read from the Solicitor to the Board, instructing them, in reply to legal information asked of him, to pay certain cheques drawn on account of Dr. Kealy, to the official assignee, Mr. James. Another official document to the same effect was also read.

Mr. Everitt considered it a very hard course; the poor man was to be deprived of his labour; this amount was due to him for his salary, and he considered that Dr. Kealy was entitled to receive it at their hands.

Mr. Leech considered that the money should not be paid to the official assignee in such a case. Dr. Kealy was entitled to his salary at their hands.

Mr. Everitt referred to a similar case before the courts in Dublin, where it was held that a current salary could not be attached in that way.

Mr. Matthews—It is a matter of law, not of sentiment. You ask a legal gentleman his opinion, and he gives it to you. I am afraid you must ultimately be guided by what he tells you.

The matter was ultimately, after much consideration, referred to the Local Government Board.

The following resolution of the committee was read:—

"That our hon. sec. be requested to represent to Dr. Kealy that, although most anxious to meet his views, they cannot continue longer to pay a substitute, more especially as his, Dr. Kealy's, salary has gone into another channel."

BOYLE UNION.

ASSISTANTS AT AN OPERATION.

THE following was read :—

SIR,—The L. G. B. acknowledge the receipt of the minutes containing a minute requesting approval of the proposed payment of a fee of two guineas to Dr. Walsh for assistance rendered by him to the second M. O. of the Workhouse in a surgical operation; and the L. G. B. have to state that some explanation appears to be called for, as to the necessity of Dr. Walsh in this case, there being two medical officers for the Workhouse.

By order of the Board,

B. BANKS, Secretary.

The Clerk then read the following from the medical officer's report :—

"The operation at which Dr. Walsh assisted was amputation of the thigh close to the body, and as it was done under chloroform, two medical men (at least), exclusive of the operator, were required, one to administer the chloroform, and one to tie the arteries."

The note made on it was :—"Dr. O'Farrell's explanation considered satisfactory."

CONVEYANCE OF SMALL-POX INFECTION.

NAAS UNION.

THE master reported that a young woman named Jane Wilson, a native of Punchersgrange, in the Naas union, had been sent into the workhouse hospital, labouring under small-pox of a most virulent type. She had been servant in the employment of a gentleman residing on the Rathmines Road, Dublin, whose daughter died of small-pox, and she was put to wash the clothes belonging to the deceased young lady, and consequently contracted the disease, and was sent to her home, from where she was sent to the house by Dr. Sale, the medical officer of the workhouse.

Chairman.—The case is one of the worst type. If death does unfortunately follow, it would be as well to have inquiry into the truth of the girl's statement.

The Master.—She said she did not know what the young lady died of when doing the washing, but found it out after. The medical officer of the workhouse said it was one of the worst cases ever in the house.

Clerk.—Or how can we tell she had the disease when she left the doctor's house?

The Master.—She says she came home ill.

The subject then dropped.

Dr. Sale wished the board to make an order to have her father's house disinfected, and the clothes and bedding burned.

The board made an order accordingly.

SLIGO GUARDIANS.

THE PAYMENT OF SUBSTITUTES.

Mr. KERRIGAN, hon. sec. to the Carney dispensary, asked that a resolution should be passed directing that Dr. Roe should be paid six guineas for acting as *locum tenens* in Cliffoney, between the date of his retirement and the apppointment of his successor, Dr. O'Neil.

Mr. Collery asked why should the ratepayers pay £4 and £6 to this doctor, when the fact was he only went from one district to another to better himself? It was £10 thrown away for nothing. It is a monstrous thing that £10 should be paid away in this manner; and it is not since I became a member of the board I looked on such payments as ridiculous.

Mr. Kerrigan.—Dr. Roe, being appointed to Carney dispensary, sent in his resignation on the 19th February; and the committee could not make a new appointment till March 19, and in the meantime they appointed Dr. Roe to do the duty as *locum tenens*. The dispensary could not be left without a doctor, and Dr. O'Neil was then appointed, but he did not take charge till the 1st of April, and Dr. Roe had to be continued during that fortnight.

Mr. Hunter.—And Dr. Hamilton was paid as *locum tenens* in the other district, while he was getting his superannuation allowance.

Chairman.—Were two doctors paid at the same time?

Mr Collery.—It seems so.

Mr. Kerrigan.—Dr. Hamilton's superannuation allowance only took effect after he ceased to act as *locum tenens*.

Chairman.—If Dr. Roe actually resigned, and was afterwards employed to do duty, he should be paid.

Was it not in consequence of Dr. Hamilton's resignation Dr. Roe went to Carney, and was he not paid for acting in Carney and Cliffoney at the same time for ten weeks?

Mr. Kerrigan said that the appointments did not clash Dr. Hamilton was paid as *locum tenens* for Carney district up to the 19th March. Then Dr. Roe was appointed. This left the Cliffoney district without a doctor, and Dr. Roe was appointed *locum tenens* at two guineas per week, no other doctor being paid at the same time.

Chairman.—The simple question is, ought Dr. Roe to be paid for acting for those three weeks, being appointed by the dispensary committee?

Mr. Collery.—Two salaries were certainly paid for the fortnight, as Dr. O'Neil was appointed on the 19th of March, and yet Dr. Roe is paid for doing his duty for a fortnight after.

Mr. Kerrigan.—But Dr. O'Neil's salary only commences from the time he took charge.

Clerk.—That is just the question. You will have to settle whether he is to be paid from the time he was appointed or from the time he took charge.

Mr. Kerrigan pointed out that it was usual for dispensary committees to ask a newly-appointed doctor when he would be able to take charge of his district, and a fortnight or three weeks was given him to do so, a substitute being appointed and paid in the interim. If, however, the incoming doctor was not paid only from the time he commenced to discharge the duties, there would be no substantial loss to the ratepayers, and it was well Mr. Collery raised the point.

The resolution was passed sanctioning the payment of three weeks' salary to Dr. Roe, and the matter dropped.

ATHY UNION.

THE SANITARY CONDITION OF STRADBALLY.

THE following communication was laid before the board :—

"SIR,—In the case of J. Kelly, the magistrates refused to make an order to force him to make a sewer from his premises to main in street, believing that the section (10th of 29 and 30 Victoria) under which the summons was brought, applied only to houses and not to yards or premises, to which latter my report referred. I am still of opinion that the yard or premises of every house should have a proper sewer attached to it, and I beg to be informed how I am to proceed.—I am, &c., W. PERCIVAL, Medical Officer."

Clerk.—The magistrates held that the yard is not a part of the house.

Chairman.—But surely the Legislature ment to include yards, for the principal nuisance exists in the yards attached to the houses.

Mr. Salter.—The nuisance in this case is caused by the surface water flowing from the yard on to the street. It emits a very foul smell.

Mr. O'Brien.—If a nuisance exists you have ample powers to compel it to be abated without any reference to the sewer at all.

Mr. John M'Laughlin.—I would suggest that the case be brought on again, and that our solicitor be instructed to attend, as a solicitor appeared against the board in the present case.

Mr. O'Brien, P.L.I.—The premises attached to any house must certainly be considered part of that house; any other presumption would be absurd.

ENNISKILLEN GUARDIANS.

MEDICINE CONTRACT.

MR. WILSON said that as there were a number of medicines not in the ordinary authorised form for tenders, which were specially ordered by the dispensary doctors, they should be included in the contract.

Dr. Bagot said there was little doubt that the present authorised list was a perfect farce. He believed there

were medicines on it were not ordered for the last 20 years.

The Clerk said that he had been keeping a list of extra medicines ordered from time to time by the House and dispensary medical officers with a view of making a supplemental list of the ordinary contract.

The Board approved of this course.

IRISH MEDICAL ASSOCIATION.

QUARTERLY REPORT OF THE PROCEEDINGS OF COUNCIL FOR THE TERM ENDING MARCH 31, 1878.

THE following is the continuation of the correspondence with the Commissioners of Metropolitan Police respecting the duties of the police to give information to the coroner as to the medical attendant of the deceased person on whom an inquest is held.

Metropolitan Police Office,
Dublin Castle,
13th February, 1878.

SIR,—I am directed by the Chief Commissioner of Police to acknowledge the receipt of your letter of the 7th inst., and previous communication, expressing the hope of the Irish Medical Association that instructions might be issued to the police in future, "when giving notice to the coroner concerning a sudden or violent death, at the same time to inform him of the name and address of a medical practitioner (with a view to his being summoned as medical witness at the inquest)."

In reply, I am instructed to state that it would afford the commissioner much satisfaction if it were in his power to promote the object in view, but he regrets to say he is not in a position to take any step, as the law gives the police no discretion in the matter.

In Dublin the established practice appears to be to have a medical man specially set apart to act as medical witness at inquests—an arrangement which, it is understood, has been approved by the proper local authority.

I am, Sir,
Your obedient servant,
J. A. CONOLLY,
Assistant Commissioner.

Irish Medical Association,
Royal College of Surgeons, Dublin,
21st February, 1878.

To Colonel Conolly, V.C.,
Assistant Commissioner,
Dublin Metropolitan Police.

SIR,—I am directed by the Council of the Irish Medical Association to acknowledge the receipt of your letter of the 13th in which it is stated "that it would afford the Commissioner much satisfaction, if it were in his power, to promote the object in view; but he regrets to say he is not in a position to take any step, as the law gives the Police no discretion in the matter;" but the 9th and 10th Vic., cap. 37, sec. 22, enacts "that the constable or subconstables acting in and for the place where such dead body shall be found, or such death happen, shall give, or cause to be given, immediate notice thereof to the coroner of such district, *together with such information as he or they shall have been able to obtain touching* the finding of such dead body, or *such death;*" and the Council are of opinion that the name and address of the legally qualified medical practitioner (if any) who was in attendance upon the deceased shortly before, at, or immediately after the occurrence of death, is "*information touching the death*" *which could be obtained by the police, and should immediately be communicated to the coroner.* By referring to my letter of the 11th December, 1877, it may be seen that this is the first part of the request made by the Council; the second part of which hangs upon the 33rd section of the same Act, which directs that the medical witness shall be "a legally qualified medical practitioner, being at the time in actual practice at or near the place where such death happened."

In your letter of the 13th inst. it is also stated that, "in Dublin, the established practice appears to be to have a medical man specially set apart to act as medical witness, an arrangement which, it is understood, has been approved by the proper Local Authority." Although it is the fact that the practice referred to (though an illegal one) has existed, it is not the function of any "Local Authority," by its approval or otherwise of any practice, to controvert the letter and spirit of the law; and by referring to the copy of the report of the judgment delivered by the Court of Queen's Bench in Ireland, on the 19th November, 1877, in the case of "The Queen at the prosecution of Jacob v. Finlay," which I forwarded on the 12th December last, you will observe that the Court ruled that *that practice is illegal and contrary to the policy of the law*, as defined by the 33rd section.

The Council therefore trust that the Commissioner may reconsider the matter, in the hope that he may see fit to comply with their request; the question involved being an important one as regards public and professional interests, as well as due observance of the law.

In conclusion, I may again observe that the Inspector-General of Royal Irish Constabulary has already adopted the suggestion of the Council.

I am, Sir,
Your obedient servant,
JOHN H. CHAPMAN, Hon. Sec.

Metropolitan Police Office,
Dublin Castle,
23rd February, 1878.

SIR,—I am directed by the Chief Commissioner of Police to acknowledge the receipt of your further letter of 21st inst., and in reply again to express regret that it is not within the province of the Commissioner to interpret the law in the manner you have pointed out, and to instruct the police to act accordingly.

The present practice in regard to medical evidence at inquests in Dublin having been settled and approved by the proper competent authority, and not by the Commissioner of Police, he is precluded from altering or modifying the arrangement in any degree.

All that the Commissioner of Police can do is to assure you, for the information of the Council of the Irish Medical Association, that, in the event of the present system being altered by the proper local authority, so as to meet the views of the Council, the Commissioner will not fail to carry out the new arrangement.

I am, Sir,
Your obedient Servant,
J. A. CONOLLY,
Assistant Commissioner.

Irish Medical Association,
Royal College of Surgeons,
5th March, 1878.

To Colonel Conolly, V.C.,
Assistant Commissioner,
Dublin Metropolitan Police.

SIR,—Your letter of 23rd February last having been submitted to the Council of the Irish Medical Association, I am directed to observe that the interpretation of the law, as pointed out in my previous letters, is that which the Council have obtained from their law advisers (Messrs. Purcell, Q.C., and R. O'Brien Furlong), and as *that reading of the law was confirmed by the Court of Queen's Bench* on the 19th November last, in the case already referred to by me, the Council beg to suggest that the Commissioner of Police should obtain the opinion of the law

adviser of the Department on this matter, which is too important to be dealt with in an off-hand manner; the subject of this correspondence rests altogether, so far as Council are aware, on the 22nd and 33rd sections of the 9th and 10th Vic., cap. 37, viz., "The Coroners' (Ireland) Act." The Council have directed me again to point out that there is no *local* authority competent by its settlement and approval to legalise the present practice in regard to medical witnesses at inquests in Dublin, and request that you will have the goodness to inform them what local authority you referred to in your letters of the 13th and 23rd February, as having, and also whereby it is so vested with such powers. The Council are under the impression that the power of pointing out the duties of the police, and especially those defined by Acts of Parliament, is vested in the Commissioner; and that no *local* authority has any power to interfere with him in the exercise of the duties of his office.

The Council never implied that the Commissioner of Police arranged the present practice in regard to medical evidence at inquests in Dublin, but protest against his recognition of it, because it is a practice which has very recently been decided by the Court of Queen's Bench in Ireland to be an *illegal one*, and as no legislation bearing on the subject has since been enacted, the Council hope that the Commissioner of Police will take the earliest opportunity of obtaining competent advice in order that he may be thoroughly satisfied with regard to this matter.

I am, Sir,

Your obedient servant,

JOHN H. CHAPMAN, Hon. Sec.

WEEKLY REPORT OF HEALTH OF DUBLIN AND SUBURBS FOR WEEK ENDING MAY 18, 1878.

Total registered deaths in Dublin and suburbs* ...	221
Ten years average of same week	147
Excess of mortality above average	74
10 weeks ratio of deaths Rathmines	25·3 per 1,00
„ „ „ Donnybrook†	24·1 „
„ „ „ Blackrock	12·3 „
„ „ „ Kingstown	16·6 „
„ „ Entire Dublin District	36·5 „
COMPARATIVE RATIOS—London ...	20·1 „
„ „ Glasgow ...	22·9 „
„ „ Edinburgh ...	17·8 „

* District extends over 10,050 acres, and contains 314,666 persons.

† This district includes City of Dublin and Incurable Hospitals.

The number of deaths from zymotic diseases registered during the week was 57, being 28 over the average for the twentieth week of the last ten years. They comprise 21 from small-pox, 3 from fever (1 typhus and 2 typhoid), 12 from whooping-cough, 4 each from measles and diarrhœa, 2 from diphtheria, &c. The deaths from small-pox registered during the last six weeks have been respectively 15, 9, 21, 17, 12, and 21. Of the 21 recorded last week 6 are chargeable to the North City Districts, 14 to the South City, and 1 to Donnybrook. The number of cases of this disease under treatment in the Dublin Hospitals (including the temporary hospitals in connection with the union workhouses) on Saturday last was 270, against 254 on the preceding Saturday; 106 cases were admitted during the week, being 16 over the number in the previous week; 73 patients were discharged as cured, and 17 died.

Bronchitis caused 26 deaths, pneumonia 5, pleurisy 2, and lung disease, unspecified, 1. These 34 deaths are 8 over the average mortality from diseases of the respiratory organs in the corresponding week of the last ten years.

Eleven deaths resulted from heart disease, 5 from apoplexy, 4 from paralysis, 1 from brain disease unspecified, 1 from nephritis, and 2 from kidney disease unspecified.

Twenty-nine persons died from phthisis, three from hydrocephalus, 2 from scrofula, 1 from mesenteric disease, and 6 from cancer.

ON ASTHMA.

By J. B. BERKART, M.D.,

Assistant Physician to the City of London Hospital for Diseases of the Chest.

(*Continued from page* 444.)

DEFINITION, PATHOGENY, AND ETIOLOGY.

II.—IMMEDIATE CAUSES.

b. Collateral.—As the collateral hyperæmia is always the necessary consequence of an ischæmia of the lungs, respiration is thus at once impeded, both by the diminution of the blood in one place, and its corresponding accumulation in another. Intense dyspnœa may, therefore, be produced by—

1. *Meteorismus.*—Asthmatics suffer, as a rule, from the severer forms of dyspepsia. The venous congestion which, as previously pointed out, spreads in the course of time also to the intestinal mucous membrane, in consequence of the impeded circulation through the lungs, is the fruitful soil of catarrhal inflammation, so that derangement of digestion becomes as constant a symptom of asthma as the dyspnœa itself. If the quantity of the food is too large, or if its quality is unsuitable, the abnormal fermentation which now takes place gives rise to a copious generation of carbonic acid and of hydrogen, besides other gases. In this way the intestines may be so greatly distended that the diaphragm is pushed upwards to the fourth and even third ribs, and compresses in that position the bases of the lungs. Ancient and modern literature contains the record of cases in which extreme flatulence proved even the immediate cause of death. (*a*)

Some articles of food, as sugar and those containing saccharine matter, and fermented liquors, are particularly obnoxious, on account of the readiness with which they are decomposed into carbonic acid and hydrogen in contact with putrifying albuminous substances. Old and decaying cheese has, more or less, the same effect. It appears that the fungi which it contains, harmless though they are to a healthy digestion, excite fermentation when the gastric juice has lost its antiseptic properties.

Constipation is an equally frequent cause of meteorismus. Even in the healthy there is, according to Fabius, (*a*) a considerable difference in the volume of the expired air before and after defæcation—a difference that would, for obvious reasons, be still greater in the asthmatic.

2. *Embolism of the Pulmonary Artery.*—In the feeble, and cachectic asthmatics of all ages, circumstances are unusually favourable for the formation of thrombi. In the dilated veins most distant from the centre, as the femoral and saphenous, and in those also of the abdomen, as, for instance, the uterine plexus, the blood readily clots in consequence of its slackened current and of the weak action of the heart. If a thrombus is once formed, portions of it may be detached and impacted in the pulmonary artery or its branches. A slight muscular effort, or an excitement of the circulation, suffices for this purpose; but, occasionally, an embolic obstruction is produced without appreciable cause even during sleep. (*b*) The consequences vary according to the size of the occluded vessel. (*c*) If this is one of the subordinate branches, the circulation of the territory which it supplies is readily re-established, and respiration is not disturbed. But when the embolus enters, as it most frequently does, the second or third subdivisions of the pulmonary artery (Paget and Virchow), occluding a considerable space, it generally gives rise to intense dyspnœa. (*a*) Much depends, as regards the origin and persistence of the dyspnœa, upon whether the cardiac action is energetic

enough to propel a sufficient quantity of blood through the adjoining capillaries, by which alone the circulation in the obstructed part is maintained. (*b*) At best, however, this is only a slow process. Meanwhile, the collateral hyperæmia of the pervious portions of the lungs is accompanied by œdema, since the causes that favoured the production of the clot equally facilitate the passage of serum from the vessels under the increased pressure. Occasionally, the œdema is the consequence of a hydræmia, as in the case of parenchymatous nephritis. In this case a thrombus extends from the hilus of the kidney into the inferior vena cava (*c*), and not infrequently the embolism of the pulmonary artery is the first indication of the renal disease.

c. Reflex Paralytic.—Violent emotion is, by some writers, mentioned as a provocative of asthma. Most of the cases, however, related in support of this view allow also of another construction as regards their causation. (*d*) It is a matter, therefore, for future observation, whether or not mental excitement possesses the alleged influence. Should the present supposition be confirmed, the dyspnœa can arise solely from a hyperæmia of the lungs. The flushing of the face from psychical irritation suggests the possibility that a similar process may take place in the bronchial arteries, (*e*) a paralysis of the pulmonary vessels being precluded by the absence of a tonus. Or the excitement of the cardiac action may lead to congestion of the lungs, in consequence of the diminished resistance of their vessels. But all this, it must be admitted, is at present very obscure.

II. *Bronchitis.*—The bronchitis of asthmatics is, as a rule, merely an acute exacerbation of a similar chronic process, and this circumstance explains not only the facility and frequency of its occurrence, but also the absence of marked constitutional disturbance. Insidious in its approach, its sole manifestation is intense and suffocating dyspnœa, which often lasts, with more or less perfect intermissions, for days and even weeks, long after the vascular engorgement may be reasonably supposed to have completely subsided.

The origin and persistence of that dyspnœa have, on account of the seeming inadequacy of the attendant physical signs, always been the subject of much speculation. But the apparent obscurity on those points admits of a ready solution, if it be remembered that the impediment of the respiration arises, not so much from the inflammatory process as from the inflammatory product. There can be little doubt that the textural changes of the mucous membrane, peculiar to asthma, are not without their influence on its function. Even such differences as normally exist in the linings of the larger and the smaller air-tubes affect, in an appreciable manner, the chemical constitution of the secretion; (*f*) for, as the number of the mucous glands decreases with the diameter of the bronchi, (*g*) their specific activity cannot altogether be replaced by that of the epithelium alone. Thus it is that in the atrophic emphysema and bronchiectasis, the inflammation of the *anœmic* mucous membrane produces, even when its glandular apparatus is intact, only a scanty and relatively dry exudation. To this cause the "catarrhe sec" mainly owes, as is well known, its distressing symptoms, and it scarcely needs to be mentioned that these symptoms must be even more aggravated in the case of asthma. In the hypertrophous form of the disease the exudation is, on the contrary, very abundant; for the vascularity of the mucous membrane supplies a large quantity of blood, the constituents of which may easily escape through the altered walls of the vessels. But, as here the mucous glands are either destroyed or otherwise incapacitated in their function, the exuded material therefore retains, in a great measure, its original character. The serum and white blood-corpuscles, instead of being converted into mucus, coagulate and obstruct the bronchi. Essentially, this form of inflammation is a fibrinous (croupous) bronchitis; and Leyden consequently holds that this is in all probability the anatomical basis of the asthmatic seizures. (*a*) Leyden founds his opinion on the nature of a peculiar kind of crystals, which, evidently derivatives of white blood-corpuscles, (*b*) may be frequently observed in the sputa of asthmatics. Fibrinous bronchitis would thus appear to be far more frequent than is generally supposed. Indeed, the current belief as to its rareness ill accords with the fact that the fibrinous is merely an exaggerated condition of the catarrhal inflammation. But there are grounds for suspecting that the presence of the affection may be, and frequently is, overlooked. Its diagnosis depends altogether on the characteristic sputa. (*c*) When arborescent casts are expectorated, it is difficult not to recognise the nature of the disease. Yet in some cases the coagula are rolled up into pellets of the size of a pea, of a bean, or of a hazel nut, and are covered with mucus or streaks of blood; (*d*) so that their structure is discernible only when they are examined in water. In others, again, the plastic exudation is, for a time, retained within the bronchi, and here it is converted into mucus or into a puriform detritus, as it is in croupous pneumonia, (*e*) or in the thrombus of a vessel. The exhibition of an emetic may thus unexpectedly reveal the presence of a bronchial cast. (*f*) If, however, the process is allowed to proceed, the sputa may be deprived of their diagnostic aspect. Still, even then there are many instances of "catarrhal" bronchitis where flakes of fibrine and pseudo-membranes are found in the midst of the muco-purulent expectoration. (*g*)

Besides, at the time when the disease is as yet called asthma, the bronchial mucous membrane is often the seat of destructive processes, which profoundly modify its secretion. There are not only superficial excoriations (catarrhal ulcers), but, in bronchiectasis more especially, a necrobiosis extends to the bronchial muscles, (*h*) and may successively involve even the different layers of the bronchial wall, so as to convert it into detritus. (*i*) In the sputa of the cases that Leyden describes as asthma, he always found tubular, contorted structures, which seemed to consist of a substance resembling coagulated mucus. Their surface exhibited an obliquely spiral delineation, and was studded with mucous corpuscles. A narrow homogeneous-looking thread ran along the axis of each of those structures, and terminated with a few spiral twists. (*k*) Those formations seem to be exfoliated glands. They were seen in the case of a patient who applied at the Victoria Park Hospital in December 1872. The patient, aged 34, a tailor by trade, was a native of Poland, but had been resident in this country for more than twelve years; at the age of 16 he had typhoid, and at 21 he had malarial fever, which lasted for one year and six weeks. Since then he had been frequently subject to colds, but did not suffer in any way so as to be unable to follow his employment. In 1871 he noticed a glandular enlargement in the right axilla, and similar swellings soon appeared

in the left axillary and in the cervical and inguinal regions. For the last six weeks he had nocturnal attacks of dyspnœa, which aroused him towards midnight, and contined with unabated intensity for hours, until, after a very painful cough, he expectorated a quantity of a greyish white and very viscid sputum.

The patient is of middle height and well built. His complexion is very dark, and his visible mucous membranes are very anæmic. He is greatly disfigured by a chain of glandular enlargements along the sterno-mastoids, varying in size from that of a chestnut to that of a small orange. They were moderately hard, movable, and irregular in shape. The glands in the armpits were much larger. The spleen was not enlarged, and repeated examination of the blood showed no increase of white blood corpuscles. The thorax was broad, but flat, and its antero-posterior diameter was rather contracted. Respiration was abdominal, and not accelerated. Percussion of the thorax gave on both sides, front and back, a tympanitic note, and there was very feeble respiration, especially so on the right side. The heart was covered by the lungs, its sounds were feeble but clear. The pulse was small, soft, and frequent.

The sputa were about four tablespoonfuls in quantity. They were of a greyish-white colour, embedded in a frothy mucus, and very viscid, so that they could be handled with knife and scissors. Thrown into water they exhibited band-shaped masses of a pearly whiteness, and small pellets of the same colour. The former consisted of pus corpuscles, arranged in rows, and contained as it were in a fibrillar stratum. Besides large quantities of woollen and cotton fibres, and of what seemed to be zooglœa masses, there was an abundance of pavement epithelium, the octahedral crystals (fig. 1) repeatedly mentioned, either entire, or the fragments in close apposition, the structures above described (fig. 2), and, apparently, casts of the smallest bronchioles (fig. 3.), resembling almost those of the renal tubes, and studded with epithelium.

The origin and the persistence of the dyspnœa may thus be readily accounted for. The exudation itself causes obstruction of the bronchi, and the freedom of respiration can be re-established only when the obstacle is removed. But not all the sputa that are formed in the course of an inflammation are expectorated at the same time. A quantity of them remain behind, firmly adhering to the bronchial wall. So long as they are in the larger tubes, they do not interfere with respiration. The superficial breathing produces no stenotic sounds, and as the current of air is not sufficiently strong to separate the plug from the mucous membrane, there are consequently no ronchi. But when the tenacious mucus gradually softens, it loses its adhesion to the surface, and may then be readily detached from this by brisk respiratory movements, such, for instance, as laughing. In that case, following its own gravity, the mucus falls downwards and occludes a portion of the lungs.

Its separation and impaction are greatly facilitated during sleep, for here respiration is slow but deep; and in the recumbent posture, moreover, the smaller bronchi form, with the larger, an inclined plane, as it were. (*a*) Those portions of mucus act like ball-valves; they descend and rise with inspiration and expiration; and not unfrequently they are, by the efforts at expulsion, forced beneath the cartilaginous plate, which projects like a spur, at the place where the bronchi subdivide. The dyspnœa lasts as long as the obstruction, and its intensity is directly proportional to the number and the calibres of the occluded tubes. Relief is obtained only when the obstacle is removed, either by expectoration of the mucus, moulded in the shape of pellets, or by its displacement into a larger bronchus, where for a time it is harmless.

III.—*Stenosis of the Bronchi.*—The term stenosis is generally applied to the obturation of the bronchi, which is chiefly produced, not, as in the cases hitherto described, by a fluxion or inflammation of the mucous membrane, but by pressure, internal and external. In some instances the stenosis, with its consequences, is only one of a series of symptoms, and amongst these comparatively unimportant, as, for, instance, in aneurism of the thoracic aorta In others, again, the intermittent attacks of dyspnœa are the sole and most conspicuous results of such pressure, and thus tally with the definition of asthma as above given. The stenosis may be caused by—

1. *Foreign Bodies.*—Foreign bodies of various sizes and of different kinds may, unperceived, pass the larynx, and penetrate to the bronchi. This occurs most frequently from inattention to the act of swallowing, or when food or other articles are present in the mouth whilst deep inspirations are taken, as during coughing and laughing. Children seem to be most liable to such accidents. Amongst the 170 cases collected by Aronssohn (*a*) there were 95 children under 10 years, and 16 at the age of from 10 to 15 years, so that more than 65 per cent. of all cases were children under 15 years. Professor Hirsch, of Berlin recently reported the case of a girl 9 years old, who was brought to the hospital suffering from intense dyspnœa and cyanosis. She was perfectly well until the previous evening, but became restless during the night, and towards the morning the present symptoms manifested themselves. The physical examination of the chest showed the organs to be healthy. On her return home from the hospital she began to vomit large quantities of undigested food, among which were specially noticeable *pieces of a hard-boiled egg*, which, as subsequently ascertained, she had *hastily swallowed the night before.* After the vomiting she had a good night's rest, and the next day the freedom of respiration was completely restored. (*b*) Professor Henoch thinks that the hard egg irritated the gastric filaments of the vagus, and caused a bronchial stricture. But it is at least as likely that the dyspnœa was caused by a bronchial obstruction.

It appears that some emphysematous are greatly exposed to that cause of the dyspnœa on account of the uniform dilatation of the larynx and trachea which accompanies the dilatation of the bronchi and alveoli. (*c*) Patients of this class are frequently seized with an attack when they are spoken to during meals; but they remain free from oppression at the time when their attention is not diverted from the business in which they are engaged. Hamburger lately recorded a very instructive case, which, although its symptoms differ from those peculiar to asthma, yet bears upon the present question. An old farmer complained of indefinite ailments, which the doctor whom he consulted attributed to some derangement of the nervous system. The patient's only daughter had recently got married, and it was supposed that his indisposition arose from a feeling of loneliness. Various means were tried, but none brought relief. As the patient constantly grew worse a visit to his daughter was proposed, with the view of remedying the evil at its root. But the result did not answer the expectations. Shortly after his arrival at his daughter's house the patient became worse—so much so that he was forced even to keep his bed. When Hamburgher was sent for the case seemed to be one of cerebral hæmorrhage. But it struck him that the right side of the chest lagged behind in the respiratory movements, and though the percussion was perfectly normal, there was, nevertheless, complete absence of respiratory murmur. There was no evidence, nor even a suspicion, of a tumour compressing the main bronchus of the right side. The presence of a foreign body in it could not be so readily excluded, and this view gained ground on remembering the fact that a cause which produces dyspnœa in the adult leads to a comatose condition in the aged. After much hesitation Hamburger at last decided to administer an emetic. He gave instruction that if vomiting took place the matter should be kept

(*a*) Traube, "Gesammelte Abhandl.," &c., Bd. ii., pp. 17-23.

(*a*) "Des Corps Etrangers dans les Voies Aériennes." Strasbourg, 1856, pp. 64-68.

(*b*) "Ueber Asthma dyspepticum."—*Berl. Klin. Wochensch.* No. 18, 1876.

for his inspection. In a few hours he returned, but great was the surprise when the patient, whose fatal end, it was feared, might be accelerated by the emetic, was sitting up in bed overwhelming his deliverer with gratitude. The sputa contained a green pea, enormously swelled with moisture. The patient remembered that on gathering peas he had eaten some, but he had never noticed that one had entered the air passages. (*a*)

2. *Compression.* — Mediastinal tumours of various descriptions are the most common cause of bronchial compression. But though accompanied by attacks of asthma, they do not properly come within the limits here assigned to asthma for this reason—that the origin of the dyspnœa in those cases is readily discernible from the physical signs and the other attendant symptoms. It is different, however, with regard to the simple hypertrophy of the bronchial glands. Participating, as they do, in all the changes that take place in the surface or substance of the lungs, their volume increases when an abnormally large quantity of exudation is pressed into the radicles of the lymphatic vessels. In the catarrhal pneumonia of measles and whooping cough the inundation of the pulmonary parenchyma with serum and white blood corpuscles always leads to a considerable enlargement of the bronchial glands. (*b*) But though this enlargement diminishes with the cessation of the inflammatory process, yet it seldom entirely disappears. The glands which accompany the bronchi to their third and fourth subdivisions are normally of the size of a lentil or of a pea (*c*); but especially in scrofulous patients, they are readily enlarged by even the slightest irritation to the size of a bean or of a hazel nut. Cruveilhier repeatedly found such glandular hypertrophy deep in the substance of apparently healthy lungs. (*d*) Thus, the bronchial tubes are flattened without being actually obliterated. Yet every fluxion or inflammation, while diminishing the calibre of the air tubes, simultaneously increases the size of the lymphatic glands, and thus produces a complete obliteration of the bronchi. For a time this glandular enlargement was supposed to be peculiar to childhood and infancy, and the intermittent dyspnœa at that period of life was correctly ascribed to it (*e*); but recent researches have shown that the asthmatic seizures of adults may also arise in the same way. (*f*)

ALCOHOLIC DRINKS: AS MEDICINES, AND AS POISONS. (*g*)

By ALFRED CARPENTER, M.D. Lond., M.B., J.P., President of the Croydon Microscopical Society, Lecturer on State Medicine, St. Thomas's Hospital, &c.

(*Continued from page* 440.)

The cases in which the temporary administration of alcohol may be useful are those in whom the surface of the body has been chilled, and in whom the powers of life are weakened in such a manner that the heart is unable to do its work of propelling the blood to the capillaries with its usual ease. The action of alcohol in these cases is like taking off the pendulum of a clock. The spring is able to work so much easier and to get over an extra amount of detail in the same space of time. Internal congestion, irregular circulation so to speak, fullness in one place, with unfilled cutaneous capillaries, are cases in which alcohol may be exhibited with immediate advantage. The tension of the capillaries being overcome, there is a diminution of the impediment to the flow of blood and, as a sequence, a possible diminution of the internal congestion. So if the action of the heart itself is too weak to overcome the tension of vessels, we may induce a kind of paralysis to enable it to do its work more easily for the time being and get over a passing difficulty in that way. How far it is prudent to push this for any length of time is another matter, as a continuance of it must lead to the first stages of tissue change, which then becomes itself of primary importance.

It appears that we may use alcohol with advantage, in moderation only, in cases of prostration from shock, and the prostration which follows acute diseases after such have expended their force, but that its continuance as a remedy is fraught with danger to those who take it.

There is a class of persons to whom alcohol may be useful even in comparative health. When the powers of life begin to decay, when the force of the heart is not enough to transmit the blood to the extremities of the body, and the aged person easily feels the influence of cold. The blood scarcely passes through the unfilled cutaneous capillaries. By dilating them and diminishing their tension the heart is relieved and the functions of the skin and other organs are more efficiently performed. A moderate dose of alcohol taken with food is always beneficial to an old person under such circumstances, and I cannot see any reason why it should not be administered. Again there are conditions sometimes present in youth, in which alcoholic drinks also are useful; no other kind of stimulant acts so equally and so satisfactorily; there are a few cases, and a very few only, in which they may be administered in middle-age; taken as a whole, a weak heart with unfilled cutaneous capillaries will be always found in those cases in which it is likely to be beneficial. The stethoscope most clearly reveals them, the impulse of the heart and the general rhythm of the pulse not at all corresponding.

So long as alcohol is taken only in such quantities that it becomes utilised at once in the equalisation of animal heat, no harm can result, but if there is more than sufficient to do this, and its specific action is produced on the blood itself, mischief sooner or later results. In this it differs from fat, with which it seems to be allied as a diet, which, if not used up, may be stored in its proper place out of the way, but the changed matter which arises from an excess of alcohol is always deposited in the tissue of an organ. Thus its effects may find a home in the capillaries themselves, interfering with their elasticity, or it may be laid down in muscular tissue, and there is then a decrease of power and so-called rheumatic pains are produced. If nerve tissue is the seat, there is interference with the power of thought, with volition, self-control, and other mental actions, the effect of which is to render the patient a weak-minded and unstable character. In health it does not prevent the waste of tissue, whilst its does prevent the discharge of effete products. There is a decrease of the formation of carbonic acid, and in this is probably found the reason why there is a decrease of temperature. It stands in the way of more beneficial actions unless it be at once used up. If there is no muscular exercise going on, or no extra mental labour called for, and no action at all required except that which keeps up temperature to a normal standard, it is hurtful; work which is kept going by continual doses of alcohol always ends in a break-down. If it is taken for the purpose of increasing muscular exertion, ultimately there is great loss of muscular power, as athletes well know. If mental exertions are kept going by alcohol, there is mental break-down, as the lunatic asylums testify; whilst it is quite impossible for organic life to be performed in a healthy manner if alcohol is habitually used to promote digestion. The evidence which was afforded by the Abyssinian and Ashantee campaigns and the Arctic expedition help to prove this, whilst the unanimous opinion of those who are competent to judge informs us that in the Russo-Turkish war the temperance of the Turkish soldiers enabled them to bear

injuries with impunity, whilst similar injuries easily caused the Russians to succumb.

It has been argued by some experts that it is unwise to leave off alcoholic drinks at once, that it is better to do it by degrees. I never could see any reason for this. The experience of all gaol surgeons is in accord with my idea, that no evil, but real good, results from immediate and total abstinence. I am satisfied that when mischief is arising from its use, it is best to immediately desist from it. If mischief then results it is because it had already commenced, and not from the abstinence; although when a man has been accustomed to his daily dose of alcohol for a long series of years, and his constitution has become acclimatised without evidence of tissue change, he should not abandon its use. I could not advise an old man to give it up; such a change would certainly do harm, not good.

I cannot leave the subject of nerve disturbances produced by alcohol without referring to the connection which exists between intemperance and crime and lunacy. Statistics are not to be depended upon, because they are not drawn up with scientific accuracy, neither are they usually based upon similars. Yet there are some facts which are something more than coincidences. There is an undoubted increase in the consumption of alcohol per head of the population. The report of the Select Committee of the House of Lords on Intemperance tells us that the consumption per head in the United Kingdom of the following articles in 1876, as compared with 1861, had increased :—

	1861.		1876.
British Spirits ...	0·68 gals.	...	0·91 gals.
Foreign Spirits ...	0·18 ,,	...	0·35 ,,
Wine	0·37 ,,	...	0·57 ,,
Malt	1·61 bus.	...	2·02 bus.

The increase was progressive year by year.

The same progressive increase was observed with regard to crime :—

	1861.	1871.
Committals for Drunkenness ...	83,196	... 203,986
Committals for Assaults	85,448	... 122,913

There is also a rise in the number of lunatics which the increase of population does not account for. In 1861 there were 39,645 under the supervision of the Lunacy Commissioners, whilst in 1875 they had increased to 63,793; and out of 39 medical attendants of lunatic asylums who were consulted by Canon Ellison, 32 replied that, in their opinion, there was a distinct connection between an increase of drinking and lunacy as either cause or effect.

The Chief Inspector of the Metropolitan Police shows us that 251,125 persons were charged at the various Police Courts in the metropolis with drunkenness in the ten years ending 1876. That more than a quarter of a million of persons had within ten years recklessly thrown away their liberty of action in the eye of the public by rendering themselves slaves to a vicious habit, is a fact which must make men thoughtful as to the future of our people.

The poisonous nature of alcohol in large and continuous doses has never been doubted, and no one can study is effects on the death-roll of this country or read Dr. Magnan's work on alcoholism without being thoroughly satisfied on that point. Dr. William Farr, in his supplement to the 35th annual report to the Registrar-General, tells us that those who supply the community with drinks, food, and entertainment in inns and beerhouses are shown to suffer more from fatal disease than any known class. He says also that the majority of the publicans and the greater part of the wine merchants are comparatively temperate, yet, as the mortality of the whole trade is high, the mortality of the intemperate among them must be excessive. In the same report the deaths amongst those engaged in the sale of stimulants is returned at 2,538 out of 74,367 persons so occupied, which gives a death-rate of 30·4, whilst 1,988 blacksmiths are registered out of a gross total of 108,939, a death-rate of only 18·2 in the 1,000; that of men in all industrial occupations was 19·9. The report tells us, not only that the poisonous effect is undoubted, but that the effect is progressing in an increasing ratio. Thus we find that in the year 1857 323 deaths were reported in which the verdict of a coroner's jury was death through excessive drinking; in 1875 the number had increased to 516. It also tells us that, whilst in 1857 294 deaths were directly attributed to intemperance, 569 were so registered in 1875. The deaths from *delirium tremens* also reached the number of 485. Thus in one year, 1875, we actually have 1,566 deaths, in England alone, directly caused by alcoholic poisoning—not one-hundredth part of those which are hastened by alcohol. But supposing 1,566 deaths had occurred from hydrophobia or serpent bites, or had happened to passengers on the railways in the kingdom, commissions and edicts and proclamations from Privy Council would have been issued, and Acts of Parliament would have been rapidly passed to provide against the continuance of this wholesale slaughter. Not so, however, with the poison of alcohol; it works its way, in a great measure, unheeded by the Legislature, except so far as it is made to be a means for increasing revenue by increasing the sale of the poison itself.

I have endeavoured to prove the truth of the proposition by statistical data obtained from the Registrar-General's publications, attested by the returns of the census commissioners; but, unfortunately, they do not refer to the same districts and are not based upon exactly the same foundations, so that the data do not correspond. There are, however, some striking points made out. Thus, taking the "England tables," the mortality in the year 1871 among ministers of religion was 666; of these 464 lived to be over 45 years of age, or 69 per cent. Taking the number of deaths among gardeners, men much exposed to vicissitudes of climate, 1,949 died, and of these 1,335, or 68·2 per cent., lived more than 45 years. Then, passing to the other end of the death roll, I find, out of 725 brewers who died in the same year, 294, or 41 per cent., only reached the age of 45, and of 2,728 publicans and eating-house keepers who died, only 49 per cent., or 1,330, were over 45. These facts show that the occupations which bring men into contact with the sale of alcoholic drinks materially shorten their lives.

When we come to deal with the character of disease which causes death, statistics do not help us. I have waded through an immense mass of figures without satisfactory result; upon this point statistics prove nothing. A reference to the physiological effect of alcohol easily explains why this is so. I have shown that its effects may fall upon any one of the excretory organs or upon any part of the nervous system. It follows that a very large number of persons may die from disease induced by a too frequent application to alcoholic drinks without the remotest suspicions in the minds of themselves or their friends that such is the case. Disease of brain, heart, lungs, kidneys, stomach, indeed of every organ of the body, may have its first origin in alcoholic excess, although the person so affected may be a temperate man and have never been drunk in his life. I have, therefore, been reluctantly compelled to put statistics aside. I have also looked carefully into the reports of the National Temperance Hospital, and have compared it with reports of similar institutions in which stimulants are freely used; but as the results, as based upon the reports, are fairly open to objection I do not use them here. The difficulty of obtaining the life history of a given case renders all hospital returns unsafe and unsatisfactory as bases upon which to found a basis for the treatment of disease. That temperance does promote length of life is a truism which even the intemperate are ready to grant, although we have not much statistical proof of its soundness. I may, however, support my statement by a return which has been kindly given me by a director of the Temperance Provident Life Office; being a statement of mortality from 1866 to 1877. The insured lives are divided into the sections, teetotal and general. The temperance section gives, as the result of twelve years'

working, 1,619 claims expected, the actual number made were 1,156, whilst in the general section 2,846 claims were expected, 2,807 were made. The claims in the temperance section were 28·5 per cent. below the expectation, whilst in the general section they were 1·4 per cent. below only. This return is a clear proof of the commercial value of abstinence.

In concluding my subject, I have only to remark that alcohol in any of its forms may be a good medicine, but is a bad diet, and that its action as a poison is visible among all ranks of society. It is our duty as medical men to advise our patients accordingly.

ON PRESSURE WITHIN THE EYE, AND THE PHENOMENA CONNECTED WITH IT.

Analysis of a communication addressed to the "Gazetta del Cliniche," of Turin, by Dr. LOUIS GIROLA.

Translated by ARCHIBALD H. JACOB, M.D. Dub., F.R.C.S.,
Formerly Ophthalmic Surgeon to the City of Dublin Hospital, and to the Dublin Eye and Ear Infirmary.

THE pressure which the liquids contained in the eye-ball exercise by means of their tension, the laws by which this pressure is controlled, and the beneficial or harmful results produced by it, have appeared of so much importance that some of the most eminent specialists, such as Donders and Coccius, have deemed it necessary to invent special instruments, to which the name of Ophthalmometers has been given, for the purpose of appreciating the effects of this pressure.

This statement need cause no astonishment, for as Dr. Louis Girola has remarked, in a well-digested dissertation, published by the *Gazetta delle Cliniche*, of Turin, the study of intra-ocular pressure embraces a wide area, whether considered from a practical or from a theoretical point of view. It extends, in fact, from the simple physiological movements of which it is the cause—as for example, the trembling of the eyelids in the cardiac systole—to the phenomena which abnormal pressure causes; as, for example, in glaucoma. Girola describes with much force and clearness, the general phenomena of intra-ocular pressure, and the serious disturbances of which it is the cause in certain pathological cases. On several points, however, the author has appeared too much inclined to generalise on the results of the observations, which have been made up to the present day; at the same time, it cannot be denied that these observations are of such value as to merit close attention, it is certain that they will become the starting point for new discoveries, forming at the same time data useful in practice for the relief and cure of an organ so essential as that of vision.

Girola has divided his work into two parts. The first contains general considerations on intra-ocular pressure; in the second, this pressure is examined with reference to: Firstly, the circulation; secondly, the phenomena, so called, of accommodation; thirdly, the muscular system; fourthly, innervation; and fifthly, the physical condition of the ocular tissues.

The eye, lying in a cavity entirely closed and full of liquids, the pressure, according to the laws of physics, increases in proportion to the compression of the liquids, or to any diminution in the capacity of the ocular cavity.

There will be increase of intra-ocular pressure, either in consequence of some exterior pressure, or from the accumulation of liquid in a greater quantity, as in glaucoma, and in serous iritis.

This increase may be relative to certain points; this is what occurs in cases of ulcers of the cornea; at those points where the resistance diminishes, the pressure increases in force.

There will be diminution of intra-ocular pressure; firstly, if the quantity of liquid decrease, as in paracentesis of the cornea in cases of atrophy of the eye; secondly, if external pressure be withdrawn, as for example on the removal of bandages.

If we consider, further, the state in which the liquids contained in the eye are found, we will quickly recognise that they must exercise, by the mere fact of being enclosed in a cavity, a dilating force on the membranes which surround them. Now, this pressure, according to a principle established by Pascal, acts equally in all directions. In its normal condition, the eye has not the form of a perfect sphere, being slightly elongated in the antero-posterior direction, in consequence of the prominence of the cornea; it is in reality a spheroid; nevertheless, in cases of excessive intra-ocular pressure, the eye becomes a perfect sphere. In fact, as may be proved by solid geometry, it is in this form that a cavity without change of superficial area, attains its highest degree of capacity. It may then be established as a principle, that when the walls of the ocular cavity have a uniform power of resistance, the eye becomes a perfect sphere. In support of this argument, the author cites as examples: firstly, that which occurs in cases of glaucoma, when the slight prominence which existed in the normal condition at the point of junction of the cornea and sclerotic, is found to have entirely disappeared; secondly, the fact that the injection of water into the eyes of dead bodies, causes them to assume a perfectly spherical form.

It may be remarked, however, in certain pathological cases, that the spherical form is not the only one produced in cases of extreme tension. The reason of this being that the covering is not equally resisting at all points.

There are certain parts capable of distention which yield, especially when disease is present. This is the reason, says Girola, that in cases of ulcers of the cornea, softening taking place, the intra-ocular tension augments in the parts attacked, with development of keratocele, and of staphyloma, of which the progress becomes more rapid as the resistance decreases.

The author then passes in review the different envelopes of the liquids of the eye; he examines the power of resistance of each. The sclerotic, the real skeleton or framework of the eye, in which the transparent cornea is fixed, presents in its superior part a thickness of 1 millim.; in its anterior part of 0·9 millim.; at its equator of 0·4 millim. Formed of a supple and fibrous tissue, it is endowed with a certain amount of elasticity, and can be distended to a certain extent, thus permitting the eye to contain a greater quantity of liquid than usual, and preventing, in this manner, a stronger compression of the internal membranes. With regard to this elasticity, the sclerotic may regain its former size; this change can, however, only take place under certain restrictions, and on condition that it has not suffered from a too prolonged action, for it must not be forgotten that we are considering a condition of imperfect elasticity. At its posterior point, the sclerotic gives admission to the optic nerve; it is penetrated at this point by numerous passages which the ciliary arteries traverse; by reason of this, even in its normal state there is less resistance. At its equator, the sclerotic is protected by the straight and oblique muscles; nevertheless it here meets with intermuscular, yet resisting spaces. The cornea itself is thicker at the edges than at the centre, but since its upper part is sheltered by the superior eye-lid, in case of disease, it gives way with greater facility at its centre or lateral parts than at the upper.

The choroid which adheres to the internal surface of the sclerotic, the retina which lines the posterior part of the choroid, give way as easily. In the first place the choroid is a vascular membrane, and, secondly, between the choroid and the retina the adherence is slight. There is only the pigmentary layer placed between the choroid coat and the cones of the retina; the latter may be considered as being kept in its position against the choroid by the peripheral pressure of the intra-ocular liquids. If an eye be opened in such a manner as to allow the vitreous humour to escape, in part, at least, the retina will become detached, and will curl up like the flower of the convolvulus, while the choroid will continue to adhere to the

sclerotic. Consequently, the liquids which are situated between these membranes can easily detach the retina, and then form an accumulation in the lower parts, in such a manner that in many cases where the intra-ocular pressure diminishes, the retina, from the fact of a less dilating pressure being exercised, must lose its connection with the choroid.

The absence of protection for the posterior part of the eye-ball and the summit of the cornea causes the intra-ocular pressure to be concentrated, especially towards the middle of the cornea, and towards the posterior part of the eyeball. This occurs more particularly during contraction of the straight muscles.

(To be continued.)

THE INNER LIFE AND ECONOMY OF A LOCK HOSPITAL IN INDIA. (a)

By Surgeon-Major W. CURRAN,
Army Medical Department.

Finding no allusion to the subject of lock hospitals in India in any of the books or periodicals to which I have access, and having experienced some difficulty in compiling a report of the institution of which I have been in charge here since April, 1877, it occurs to me that an account of the manner in which such establishments are organised or managed may be acceptable to other than local readers. I am induced, with this view, to prefix some explanatory matter to the report in question, to enable it to appear in an intelligible form in this journal; and I hope to be able to add to it such further information respecting the inmates as may appear to me to call for record or preservation. The report itself—which is somewhat curtailed of its original proportions to avoid unnecessary detail or technicality—is conceived in this spirit, or so constructed, as though addressed to a particular hospital or audience, to be susceptible of a general application; and its perusal may, perhaps, prove more instructive or interesting at home than it could hope to do in a government cover out here. It may further help to throw some additional light on the troubled question of the licensing and registration of prostitutes, or tend to strengthen the hands of those who, like myself, seeing no other mode of escape from a greater evil, desire to regulate or restrain the vice of prostitution, in the hope of controlling or diminishing, through such restraint, the ravages of a most subtle and dangerous disease. From this standpoint only do I undertake to deal with the question. I speak as a sanatarian, or a physician, rather than as a moralist, or a legislator. Yet do I recognise no alternative or *via mediæ* in the case, and I have no sympathy at all with the squeamishness which turns up its eyes in horror at the very mention of the practice, or which affects to ignore an institution that has flourished so long—that, in short, is known, "ubique et ab omnibus."

But though the objections that are so frequently and persistently urged against the registration of public women in Great Britain scarcely apply out here, yet it is desirable to take some account of them in the interests of the soldier and the State; and with this view a glance at the status and surroundings of the Indian Cyprian will be necessary. Be it known, then, that little or no reproach attaches to the practice of this profession in India, and that many of these women are brought up to it almost, it may be said, from their cradles. Some of them have, as we shall see further on, children for whom they can scarcely hope to provide in any other way. Others are drawn into the vortex through want, or at the instigation of their parents; and the Hindoo religion lends a certain amount of encouragement to their existence, by sanctioning their presence at some of its ceremonials. This may be inferred from the "Prem Sagur," one of the sacred books of this creed, as well as from Mills' "History," (a) or Moore's "Hindu Pantheon" (b); and English readers may, perhaps, remember the horror with which the heroine of Meadows' "Taylor's Tara" contemplated the possibility of her becoming a "murli," or dancing girl, at the tempie. They take no shame to themselves, or express no remorse for the life they are obliged to lead under the contingencies just described. Prostitution is, in a word, almost as much a matter of necessity with these women as is the trade of the washerwoman, or the nurse, to their more virtuous sisters; and such being notoriously the case no degradation can be possibly entailed on them, by a "simple process of surgical manipulation." (c) They would laugh at the idea, for they well know that the gradations of caste oppose insuperable barriers against their employment in any other sphere, and they know nothing or care less for those guarantees of public liberty, or personal freedom, of which so much capital has been made by the opponents of these enactments everywhere. What they object to is the restraint which the cure of their ailments sometimes entails; but this resentment is as often, or oftener, due to the damage this confinement does to their business than to any sense of injury or feeling of injustice or oppression. The *Civis Romanus* cry is never heard amongst them.

Again, the system now in force is little more than a prolongation—a legal one if you so prefer—of the old plan, whereby a certain number of these women was attached to corps "under regimental arrangements." (d) They were told-off for duty, like their neighbours the sweepers, the punkah-pullers, or the dooley-bearers. They marched with the regiment from one encampment to another; they accompanied it to the camp or in the field, like their sisters in the Spanish army under Alva. (e) They were housed in the Bazaar, and examined once a fortnight or so by a Native or European subordinate, at the discretion of the medical officer. Though they were, of course, at liberty to object to this, or even to go away altogether if they chose, they rarely availed themselves of either privilege. Their bread, in short, depended on their compliance; and the government knowing all this, knowing also that opposition on its part would not only be fruitless but positively injurious, wisely determined to take the bull by the horns, and deal with the matter on the broad basis of necessity

(a) It may be necessary to explain, for the benefit of those who do not understand Hindoostani, that the word "purka" means, in reference to a well, wall, or building, masonry, as distinguished from clay; while the words "dhai," "chowkedar," and "bhistie," mean respectively a nurse, a watchman, and a water-carrier.

(a) "The History of British India." Vol. i. Pp. 365-7.

(b) "The Hindu Pantheon." Pp. 199-422.

(c) These phrases are taken from the prejudiced but able work of Mr. Sheldon Amos—"Laws for the Regulation of Vice, &c."—who holds that "this unremitting surgical manipulation of women for the direct purpose of ever-renewed vice cannot fail to degrade them generally in their own eyes and in the eyes of others;" and whose arguments in that direction I had, at first, intended to combat. But these assume a civilisation, or a refinement, such as is quite unknown out here. They also assume an amount of cultivation on the part of the home prostitute, which her Indian sister does not possess; and the moral standard or social surroundings are too different to admit of any comparison being made between. Holding with Mr. Lecky, that the prostitute—especially so the Indian prostitute—"is ultimately the most efficient guardian of virtue!" I have clearly no common platform with Mr. Amos; and this being so, any further discussion or definition of his views would be irrevalent or useless.

(d) See this system well described in the book just referred to, viz., "Laws for the Regulation of Vice." Pp. 168-91.

(e) Describing the advance of a Spanish army under the Duke of Alva towards the Netherlands in 1567, Mr. Motley says: ("The Rise of the Dutch Republic." P. 340) that "with an army thus perfect on a small scale in all its departments, and furnished in addition *with a force of two thousand prostitutes, as regularly enrolled, disciplined, and distribut d as the cavalry or the artillery*, the Duke embarked upon his momentous enterprise . . . at Carthagena;" and this, too, for a quasi religious purpose. Froude confirms this ("History of England." Vol, viii., p. 431), whereat he says that "he (Alva) took with him ten thousand soldiers, complete in all the essentials of an army, *even to two thousand courtesans*, who were under military discipline"—in other words, who were required to submit to the "simple process of surgical manipulation," that is so much objected to by Mr. Amos and his followers.

and common sense. Hence the system now in force, and which this report is intended to elucidate as far as it goes. The results already achieved by it are such as to leave no doubt of its value from a sanitary point of view ; and it is quite within my own personal observation that primary sores and sloughing buboes were much commoner in military circles when I came to India, seventeen years ago, than they are at present. Indeed, they are now the exception rather than the rule ; and the head-quarters' wing of the regiment to which I have been attached since February, 1876, and which has averaged a strength of 408·18 men during that time, has had very few of either. Out of 175 venereal admissions 32 only were of the former description, while there were only 9 cases of bubo, or simple inflammation of the inguinal glands ; and I have no doubt at all that had we access to the statistics of the same corps, or of any other similarly constituted body of Europeans, of the soldier age and class in former times, we would have a very different story indeed to tell.

Whether this system deserves encouragement on other grounds is not for me to determine. It is more a question for the theologian or the law-giver than for the medical jurist or the statistician. Sumptuary laws have, however, ever been bad laws, and it is now, I believe, generally acknowledged that the efforts heretofore made for the suppression of this vice have produced worse effects than those they were intended to combat. It was so under Puritanism in England, as well as under Presbyterianism, as that is painted by Mr. Buckle, in Scotland. A king of France used its indulgence or its abuse as a lever to destroy a powerful religious order ; while a king of England turned a similar imputation to good account in his dealings with the monasteries ; and it would be hard to decide, in the present day, between the morality that is inculcated in the "Fruits of Philosophy" and that which is practised by some of the societies described by Mr. Dixon. So strong is the sexual passion in most men, says Dr. Parker, that "it often leads them to defy all dangers and risk all consequence ;" and Juvenal described practices in Rome, in comparison with which Indian prostitution is purity itself—

> "Sed jacet aurato vix ulla puerpera lecto
> Tantumartes hujus, tantum medicamina possunt,
> Quæ steriles facit atque homines in ventie Neandos,
> Conducit."

The hetairai (*a*) of Athens played a part in the days of Pericles which influenced the civilisation and the policy of Greece, and through these, of the world ; and it is clearly the duty of the State to watch over the safety of those who serve it. This, doubtless, was the view the Government took of the situation. 'Tis certainly the view I take of it ; and bad as this system undoubtedly is, nevertheless it is better than none at all, or than its equivalent, the old weak system or spirit of connivance and compromise. It has already deprived the disease, as I have shown within, of much of its sting—it is rendering the British army in India yearly more efficient than it was, and if the Government will only persevere, or even enforce the authority it already possesses, it will in time rob syphilis of its virulence in this country, and possibly minimise its consequences throughout the world.

(*a*) "Very different from the social position of chaste women was that of the hetairai (of Athens, &c.). We are not speaking of the lowest class of unfortunates, worshipping Aphrodite Pandemos, but of those women who, owing to their beauty and grace of conversation, exerted great influence even over superior men. We only remind the reader of Aspasia. In the graces of society the hetairai were naturally superior to respectable women, owing to their free intercourse with men ; for the hetairai did not shun the light of day, and were not restrained by the law, only the house of the married man was closed to them."—"The Life of the Greeks and Romans." By E. Guhl and W. Koner. P. 195. And though the poor unfortunate creatures to whom I refer can lay no claim to the accomplishments here indicated, yet do they bear a considerable resemblance to their more favoured or fortunate sisters ; and the situation is otherwise so much alike in both cases as almost to admit of our saying of it in the latter—
"Mutato nomice de te fabula narratur."

Annual Report of the Lock Hospital at Sitapur for the Year 1877.

Hospital Accommodation, Inspection, and Establishment.—The building used as a lock-hospital in this station, was formerly the hospital of a native infantry regiment, which has been repaired and adapted for its present requirements, at the cost of the cantonment funds. It is conveniently situated in rear of the European barracks, and within easy reach of the sudder and regimental bazaars, capable of accommodating a much larger number of diseased women, than we are likely to be burthened with, under the restrictions that are now imposed on the diffusion of vice in this cantonment, it is quite sufficient for our local wants, and a considerable portion of the building remains virtually unoccupied. As regards the occupied parts, which consist of two airy and well ventilated wards, that might receive, without any fear of over-crowding, from 16 to 20 women, these are surrounded by a clay wall of some eight or ten feet high, which separates them entirely from the outer world, and the enclosure in which they stand is provided with a good "pucka" well and "rear," as well as, with a cook-house and lumber-room of the same construction. Owing to the fractiousness exhibited by, or the even suicidal threatenings, with which some of these women resent their detention, a grating has been placed, at my request, over the mouth of the former, and the dry-earth system of conservancy is, as far as possible, enforced in the latter.

Examination Room and Sub-Committee Office.—The examination-room and hospital office, the latter also being used as a dispensary, &c., though outside the enclosure, are yet under the same roof, and there is a separate masonry "rear" for the use of the servants, &c., of the establishment hard bye. These several structures are under the control of the resident Dhaï and Chowkedar, they are visited daily by the native doctor on duty, and I can testify from frequent personal inspection, that, the general surroundings and economy of the building are in a good sanitary state.

A sub-committee of the standing station board of which the deputy commissioner is an *ex officio* member, visits the institution once a month, when, any representations I may consider it my duty to make, are considered or recorded, and the following table so fully describes the accommodation available for hospital purposes, as to preclude the necessity of my going into further detail on the point, in this place.

Table No. 1.—*Being a return showing the Measurements of the Wards, &c., of the Lock Hospital at Sitapur.*

Wards.	Length, in feet.	Breadth, in feet.	Height, in feet.	Area, in feet.	Cubic contents, in feet.	No. of Beds.	Remarks.
Main Ward	47	20	14¾	940	13,865	10	There are also two attached compartments, in which as many tubs are kept for ablutionary or other purposes ; and these are not included in the measurements submitted herewith.
Ward at north end	22¾	20	14¾	455	6,711	6	

Establishment.—The establishment at present entertained consists of

1. A Medical Officer on Rs. 50 per mensem.
2. ,, Native Doctor ,, ,, 10 ,,
3. ,, Bhistie & Cook ,, ,, 10 ,,
4. ,, Sweeper ,, ,, 4 ,,
5. 4 Dhais on 6s. each ,, 24 ,,
6. A Chowkedar ,, ,, 4 ,,

Funds for the payment of the establishment were heretofore provided out of local sources, but these having failed or become so much reduced by the long continued drought of the last summer, as to be no longer sufficient, an application had to be made for aid, through the mili-

tary authorities, to the Government of India, to supply the deficiency, and this has been recently afforded. The wages, &c., that were in arrears, since September last, have been received by me, through the station staff officer, and duly paid up to the 31st December last inclusive.

Police Control and Medical Superintendence.—Three police detectives are specially told off, for the purpose of preventing secret or unlicensed prostitution, whose duty it is to look out for and arrest such villagers or vagrant women as they may find out, at unseasonable hours, in the jungle or under trees, or as they may have reason to suspect of irregular practices elsewhere. The barrack-police are also warned in the same direction, and speaking generally, I may say that the police control or supervision has been, on the whole, efficiently carried out during the year. Cases of hardship or improper arrest do, doubtless, sometimes occur, but these are disposed of by the cantonment-magistrate, and so lax or ill defined are the relations between many of these women, and their paramours, that it is not always easy to draw the line between actual prostitution and mere concubinage. Some of them undoubtedly ply their vocation promiscuously, while living nominally, under the protection of some sawar or other native official, others say they cannot be diseased, inasmuch as they confine their favours to some individual or within a very narrow circle. But I find that one class is just as liable to disease as the other, and so make the rule in regard of an examination absolute, unless indeed, I am told officially, that such or such a person is entitled to exemption, on the score of her being married or otherwise provided for.

Medical Officers.—The medical officers who held charge of this hospital during the past year, were surgeon Carter, M.B., A.M.D., Surgeon Major Ellis, M.D., civil surgeon, and myself, and the following was the morning-state of the same, as this was prepared on the occasion of the deputy surgeon general of the circle's inspection thereof, on the 27th of December last. It must speak for itself.

TABLE No. 2.—*Being the Morning State of Sick in the Lock Hospital at Sitapur on the 27th December*, 1877.

Diseases.	Total.	Remarks.
Abrasions ..	3	This may be regarded as, on the whole, a fair representation of the character and classification of the prevailing diseases. It is, however, somewhat under the average as regards amount, &c. Cases of ulceration of the cervix are rarely admitted, as it is found that they do not spread infection; and they are, moreover, very intractable to treatment. The women themselves are often quite unconscious of its presence, and it rarely gives rise to any local irritation or discharge.
Gonorrhœa ..	2	
Leucorrhœa ..	5	
Ulcer of os uteri	1	
Total ..	11	

Amount of Disease and Mode of Examination.—The venereal disease noticed by me during my tenure of office as medical officer to this Lock Hospital, were of a mild character, and such as were susceptible, for the most part, of speedy cure. They consisted chiefly of leucorrhœa of the cervix and abrasions of the os. Next in point of frequency is gonorrhœa, and fortunately so, for this is a very intractable malady, when it occurs in a virulent form in the female. And women, especially so, young women suffering from it have often to be detained for weeks together under treatment to insure immunity on their part against a relapse. Relapses do occur, however, frequently, in spite of all endeavours to the contrary, but this discharge, rarely, if ever produces much disturbance, constitutional or otherwise in these women, and I have not yet seen a bubo in any of them, as a consequence of this or any form of venereal. Neither is primary syphilis common amongst them, and they do not appear to suffer at all, anyhow, not so frequently or so severely from the sequelæ of this disorder, as do their sisters of the same craft in the cooler west. I have looked in vain at, or questioned to no purpose, the older prostitutes of this class who come before one for evidence in point. Many of them, most indeed, are as free from traces of this taint, as the younger Cyprians, and I have seen more disease of this latter kind in one day in a London hospital, than I have witnessed in a whole year among these women.

Many of the older prostitutes, however, suffer from a species of ulceration of the cervix, the result, doubtless of old standing irritation, or rather, perhaps, of a low form of inflammation of that canal, which is, in some instances, almost incurable. Anyhow, the remedies I have used, chiefly nitrate of silver, or black-wash, applied locally, have utterly failed to effect a cure in these cases, and nothing less than the actual cautery, nitric acid, or potassa fusa, would, I think, avail. There is, however, no time or proper appliances at my command for carrying out this treatment; these women submit with the greatest reluctance to any restraint, and the propriety of incurring the expense, this experimental therapy would entail may be doubted. Fortunately this condition does not appear to be communicable to the male, at least, I can find no evidence to that effect in the course of my inquiries or experience here, and so I now rarely admit women of this class.

All menstruating women are detained during their periods, and the following table must speak for itself. It shows, at a glance, the amount and character of the diseases, for which treatment was enforced, and this treatment mainly consists of localised cleanliness, and astringents. The patients are made to stand or sit in a tub of water, and then freely drenched by means of a syringe, concentrated solution of alum, zinc, or other astringents, are subsequently squirted into the vaginal canal, and this process is repeated several times a day. Nitrate of silver, in stick or solution, is also used, so is black-wash, or a solution of sulphate of iron, gr. iii, v. ad. ʒj., and we give steel-drops, or other tonics, as the indications for these prescribe or require.

TABLE No. 3.—*Being a return of the Diseases that prevailed during the past year, as well as of the Number of Admissions that took place under each.*

Year.	Average No. of Prostitutes.	Diseases.					Time under treatment.		
		Leucorrhœa	Gonorrhœa.	Abrasions.	Primary Syphilis.	Other Diseases.	Abrasions 1,882 days	Leucorrhœa 1,308 days	Gonorrhœa 1,375 days
1877	108·45	108	57	111	31	18	Remarks.		
							The number of admissions to strength appears unusually large, but many of these "abrasion" cases were of a trivial character, such as other officers might hesitate to admit; and their specificity may, in many instances at least, be doubted. No corresponding lesions have been found amongst the troops; and, as regards the other conditions, they include such intercurrent complications, as—hæmorrhoids, warts, rectal-abscesses, ulcers, &c., &c.		

(*To be continued.*)

It is understood that re-election to the Professorships of Surgery and Pathology, and of Dermatology, in the Royal College of Surgeons of England, at present held by Mr. Spencer Wells and Mr. Erasmus Wilson respectively, will not be again sought by those gentlemen. The other professors seek re-election. Applications for the various Chairs should be sent in to the President of the College, on or before the 12th inst.

OBSERVATIONS OF THE KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND, ON THE CLAUSES OF "THE MEDICAL ACT, 1858, AMENDMENT BILL, 1878."

THE College have very carefully considered the Bill, and are of opinion that while it contains some points which deserve their approbation, others of the proposed amendments will fail, in the opinion of the College, to meet the acknowledged existing evils in medical education and examination. The College observe with regret that no provision is made in the Bill for the reform of the General Medical Council, and they are of opinion that the members of the medical profession, practising throughout the United kingdom, are entitled to direct representation on the General Medical Council, and, that such direct representation would be for the public good.

Clause 1.—In substance approved.

Clause 2.—In substance approved.

Clause 3.—This clause, providing the necessity of a double qualification, in medicine and surgery, for registration, is the most valuable in the Bill. It does not, however, provide for proficiency in midwifery:—this, the College consider a defect—and they are of opinion that none but persons whose qualifications have been tested in medicine, in surgery, and in midwifery, should, in future, be admitted to the Medical Register.

The College have made several attempts to form, with the other Licensing Corporations and Universities in Ireland, a Conjoint Examining Board; and, although such endeavours have been fruitless, the College concur with the resolution passed by the General Medical Council in 1870, and re-affirmed in April, 1878, "that a Joint Examining Board should be formed in each of the three divisions of the Kingdom," and, "that every person who desires to be registered under the Medical Act shall be required to appear before one of these boards for examination in the subjects which may be deemed necessary by the General Medical Council."

Clause 4.—The College object to the intention of clause 4, as they are of the opinion that it is not desirable to transfer to the register of the General Medical Council the powers possessed by the registrars of the several branch councils under the *Medical Act* (1858) to register duly qualified persons, and to receive the fees payable by such persons for such registration.

Clauses 5, 6, 7, 8.—Deal with the registration of colonial or foreign practitioners with recognised diplomas.

The College approve the intention of these clauses, but consider that, in justice, their provisions should be limited to such colonies and foreign countries as extend like reciprocal privileges to holders of registerable diplomas obtained in Great Britain and Ireland.

Clauses 8, 9, and 10.—Approved in substance.

Clause 11.—Dealing with the erasure from the register the name of practitioners guilty of disgraceful conduct or convicted of a crime, is approved, except such portion of the clause as provides exemption from its operation to persons who have been guilty of an offence *trivial* in its nature, or committed under excusable circumstances.

Clause 12.—Approved.

Clause 13.—The College consider that questions relating to the erasure of names from the *Medical Register* for infamous or disgraceful conduct in a professional respect ought to be reserved for decision by the general body of the General Medical Council.

Clause 14.—The College approve the powers given to the General Medical Council by this clause, to deal with and determine all the regulations of the examinations of persons desiring to obtain a double qualification, but they take exception to section 2 and sub-section (*b*) of section 4;—to the former, because the effect of the examination rules not requiring a candidate to adopt or refrain from adopting the practice of any particular theory of medicine or surgery would be that candidates, under such a plea, might evade the questions put to them by their examiners; to the latter,—which permits a woman to object to the same examination as men—because, in the opinion of the College, no difference whatever in the mode, conditions, or scope of examination should be made between male and female candidates.

Clause 15.—Authorises a scheme for establishing joint medical boards for conducting medical examinations.

The College (*vide* remarks on clause 3) are of opinion that any compulsory conjoint examining scheme for each division of the kingdom should include in its operation the universities as well as the medical corporations.

Clauses 16 *to* 21.—Approved in substance.

Clause 22.—Deals with penalties for the unauthorised assumption of titles by unregistered persons practising medicine orsurgery for gain.

This, in the opinion of the College, while useful, falls short of what is much needed in patting an end to illegal abuses; for the penalty should be not *alone* on those who assume certain titles to which they have no legal right, but *also* upon those persons who, for gain, practice medicine or surgery, and are not registered.

The College further disapprove of the clause, so far as it deprives private persons of the privileges they now enjoy, of instituting prosecutions for offences under this section.

Clause 23.—Provides for the examination and registration of dentists.

This clause is very objectionable, as, not only is it contrary to the principle of the Bill, which requires a Qualification in both medicine and surgery, to admit to general practice, but, further, it would permit a person who is not a surgeon, or not in possession of any recognised medical or surgical qualification, to be registered as a legally recognised dental practitioner, and qualified to practise dental surgery.

Clause 24.—Deals with the examination and registration of midwives.

The College acknowledge that it is desirable that competent midwives should be duly and legally qualified. They are, however, of opinion (1) that it would be better to alter their designation to that of "Midwives and Nurse-tenders;" (2) that the licensing of midwives should be confined to properly constituted *Medical* bodies.

The miscellaneous clauses approved.

J. MAGEE FINNY, M.C., Registrar.

May 21, 1878.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, JUNE 5, 1878.

THE NEW MEDICAL BILL.

SINCE we last wrote on this subject, important amendments have been made in the Bill—amendments with which the great bulk of the profession cannot fail to be

satisfied. As we remarked last week, it was not to be expected that the Lord President would so far yield to the pressure put upon him by the deputations he received as to concede all the points on which they laid so much stress. But, with regard to that more urgent question of medical reform, the establishment of conjoint boards, the Lord President has very willingly and graciously yielded to the many representations that have been made to him in their favour. He sees that it is not advisable to let the prejudice and compunctions of the Scotch corporations stand in the way of those reforms in which both the profession and the public are so much interested, and which, whatever difference of opinion there may be in respect of other clauses of the Bill, have been very generally approved of. The Conjoint Scheme, therefore, is now to be made compulsory in the three divisions of the United Kingdom, not only with regard to the corporations, but also as respects the Universities. All persons having passed the examinations of the Conjoint Board will be entitled to claim the diploma of any one of the corporations that have combined. We use the word "person" advisedly, for, by the new Medical Act, women can claim to be admitted to the conjoint examination; if they pass this it will be scarcely within the power of the corporations to refuse to grant to women the same diploma that they grant to men after passing the same examination. According to the new Bill in its original shape, women were to be admitted to the conjoint examination, but the corporations were not to be compelled to give to the successful candidates their respective diplomas or licences. This was evidently a restriction that could not be allowed to stand, for if women are admitted to the Conjoint Board examinations, and are able to pass them, it would be absurd to think of depriving them of the privileges always claimed in such cases by the successful male candidates, more especially as no distinctions will be probably made between the sexes in respect of the kind and severity of the examinations. For, in reply to a deputation from the London School of Medicine for Women last Friday, the Duke of Richmond and Gordon said that the Government had no intention of making any difference between the examinations and status of candidates, and pointed out that if any distinctions were made in the examinations they should yet "guarantee equal proficiency." His Grace would, however, consider whether it might be feasible to omit from the Bill all mention of possible distinctions in examination. In our last issue we said so much about the necessity of making no distinctions in this respect between the sexes that we shall now only express the hope that the Lord President will find it "feasible" to remove from clause 14 the objectionable provision to which he refers. But to return to the Conjoint Board, it will be seen that the successful candidate (male or female) will be entitled to practise, and to have his name placed on the Register, and the public will have the satisfaction of knowing that, whatever may be his titular qualifications, he has passed a board in whose examinations it can put the greatest confidence. This is the great point gained, for, as regards the titles which the successful candidate will be able to claim, some exception may be taken to the proposed arrangement. It may seem a rather awkward arrangement for the candidate, after having passed the examinations of the Conjoint Board, to take the diplomas of corporations which, as examining bodies, no longer exist, and a title more indicative of the board which had been passed will appear to many more dignified and logically correct than that which it is now proposed the successful candidate should bear. This, however, is a matter of secondary consideration. So long as the public and the profession know that there are only three instead of nineteen examining bodies, and that no student will be allowed to enter upon practice until he has passed examinations the standard of which is more uniform and higher than it has ever been before, any little amendment of a formal nature may be easily left for future consideration.

Seeing, therefore, that the Duke of Richmond and Gordon has conceded so much, and on a point of such vital importance to the profession and public, would it be advisable to risk the passing of this Bill, by insisting upon his Grace making still further amendments? In our last issue we said nothing about the agitation now going on in favour of a direct representation of the profession in the Medical Council, and for this reason, that while the question of Conjoint Boards was a serious question, and the immediate settlement of which was earnestly called for, the other question of medical reform is one that may very well stand over to a future time. Were the direct representation of the profession in the Medical Council easily practicable there might be some reason for pressing it upon the attention of the Lord President, for we are fully aware that in an abstract point of view there are many reasons why the present constitution of the Medical Council should be materially altered. But allowing the advisability of the profession being more directly represented than it now is, the difficulties in the way of carrying out such a representation are acknowledged by even those who, were it more practicable, would not hesitate to support it. Indeed, those who are agitating for this point of medical reform have failed to show how it can be well carried out. Therefore, considering the obstacles in the way of sending half-a-dozen members to the Council, who may be fairly said to represent the great body of general practitioners, it would be unwise to risk the immediate passing of a Bill from which so much will be gained, for the sake of enforcing a point of reform which, advisable though it may be, is not, as far as the interests of the public are concerned, by any means of so much importance as that which through the wise concession of the Lord President bids fair to receive the sanction of the legislature. We would, therefore, urge that this proposed direct representation of the profession in the General Medical Council be, as the Duke of Richmond and Gordon suggested, dealt with separately and on a future occasion, particularly as by this discreet delay the subject will be more conveniently and maturely considered and more successfully managed than it could be at the present time, when there are so many other things occupying the attention of Parliament and so little time left for the passing of the Bill.

VISITING PHYSICIANS TO IRISH ASYLUMS.

In a recent issue of the *Dublin Daily Express*, we find an editorial comment on a letter lately addressed by the Council of the Irish Medical Association to the Irish Lunacy and Poor-law Commissioners, on the subject of the functions of visiting physicians of district lunatic asylums in Ireland. A copy of this letter appeared in our columns, and it was intended to put the Commissioners in possession of the facts, it having been found that in reply to inquiry addressed by them to the several Resident Medical Superintendents at public asylums in Ireland—whether, "with a view to efficient administration in the asylum, and to affording protection against improper treatment or detention of inmates, the present system of visiting and inspection can be improved, or any change or modification in the existing rules can be made with advantage;" it was suggested by the same officers that an assistant resident medical superintendent should be appointed to all asylums, and that the duties of visiting physicians should be more accurately defined than they are under the existing rules.

The letter of the Irish Medical Association was not reproduced by the *Daily Express*, which we much regret, as, thus introduced, it would have made the general public aware of the increasing necessity for watchfulness against the insidious changes in the lunacy system secretly effected by the Central Department, such as no public department would have ventured boldly and openly to make. While the indisputable facts and unanswerable arguments of that letter are withheld, the *Daily Express* refers to the proposed restoration of the Visiting Physicians to their original duties, and proceeds to condemn such a proposal, relying for its argument mainly on the circumstance of the recent appointment as Visiting Physician at the Waterford Asylum of a gentleman whom it represents as "a young lad" appointed to "consult and advise" the Resident Medical Superintendent, "a graduate in arts and medicine, of high reputation in his profession, and much experience in insanity and the diseases commonly accompanying it." We altogether deprecate the attempt to deal with a great public question by a comparison between the merits of individuals, but such a method of deciding the question is especially weak in the present instance, inasmuch as the Resident Medical Superintendent (whom we are far from having the least desire to disparage by adopting the style of argument of the *Daily Express*), is very little senior in the profession to the "lad" visiting physician, and is one of those officers referred to in the letter of the Irish Medical Association, who passed almost from the medical school into the very limited professional area of a district asylum, and who, in the capacity of assistant resident there qualified for promotion to the position which he now holds. Any such argument as that put forward by the *Express*, is obviously incapable of convincing anyone, because, assuming for the moment, that the statement made therein is true, and that the recent appointment of the visiting physician at Waterford is unsuitable, a single such appointment affords no case against the existence of a Visiting Physician in connection with district asylums, which, with the Medical Association, we consider of very high importance, concurring also with that body, that those officers should be again placed in sole charge of the "bodily sick" in asylums. Without expressing any opinion upon the merits of any officer at any age, we conceive it reasonable to suppose that the case of bodily illness in a district asylum may very possibly be better placed in the hands of a physician-surgeon, in his full maturity of education and qualification, even at the early age of 22 years, than in those of a gentleman of —for all we know—not higher academic attainments, whose opportunities of improving his medical and surgical knowledge and experience have been limited to those of the very subordinate position of assistant in an asylum. We are completely incapable of understanding that an assistant to the Resident Medical Superintendent, trained from the first to forget all ever known of medicine and surgery, except of his own speciality, should be more capable of doing medical justice to the sick lunatic, than the practitioner whose daily business it is to add to his knowledge and experience by engagements in every department in the wide field of practice of medicine and surgery, and whose presence is valuable as a link between the outside public and the imprisoned inmates of asylums. This link the *Express* would feign break, professing to consider as sufficient protection for the lunatic, the occasional visits of friends and of the chaplains; friends, if any, and the chaplains, too, having their visits subject to the approval and convenience of the Resident Medical Superintendent. We have, of course, the indispensable arguments reproduced by the *Daily Express*, that there are no visiting physicians in England, and *ergo* ought to be none in Ireland, inasmuch as "they do not seem to be found necessary" at the other side of the Channel. We doubt not that the English asylums would be better managed, and the bodily sick better provided for if there were such officers in England, and we doubt not that the public would know more than they do now of the occasional broken bones which, notwithstanding present arrangements, are brought to public notice. We are persuaded that if such officers existed in English asylums, we should hear more frequently than we do of transactions similar to the cold-bath homicide at Limerick, although such occurrences would be much less frequent than they are now.

The *Daily Express* misrepresents the letter and spirit of the Council's communication, which by a careful statement points out how the existing state of things has been brought about, and recommends (not as the *Express* would have it appear, the "re-establishment of the former status in district asylums of the officer now termed the visiting physician but") that that officer shall be restored to the full charge and direction of all cases *of bodily illness*, continuing, as hitherto, to afford his advice in consultation in "difficult or peculiar" cases of "mental" disease, leaving the direction of the "moral and medical" treatment of the insane to the resident medical superintendent, who we observe has tired of his official name, and his self-styled "physician superintendent."

It is announced that the Council of the Royal College of Surgeons of England will, on the 13th of June next, proceed to the nomination for election in July of th several Professors and Lecturer for the ensuing year.

Notes on Current Topics.

The Kashmirr Medical Mission.

THERE can be no doubt that the system of combining medical and missionary work is a good one, and judging from the Report just issued by the able young surgeon and missionary, Dr. E. Downes, it bids fair to be very successful. It is impossible to make much impression of a religious nature upon the minds of the natives of India, without first gaining their affections and claiming their respect by such acts of skill and charity as can be only performed by means of a hospital. "This," in the words of Dr. Downes, "appears to be the true fulcrum on which to apply the missionary lever." From a missionary point of view, there was very little work done last year, for, owing to circumstances that could not be avoided, it was impossible that the hospital of the mission could be the centre of any religious teaching.

On the other hand, the medical campaign in Kashmirr was a very active one, and within the short period of a few months some thousands of out-patients have been seen, and some hundreds of operations performed. The following extract from his diary will give the reader some idea of the work that an English missionary has to do :

"June 5th.—No out-patients, operating day. Dr. Ross and Dr. Lewer came to help me. I saw a case of lupus exedens: one side of a boy's face was quite destroyed ; I could do nothing. I operated on two eyes for trichiasis by Stellwag's plastic operation, which Macnamara recommends ; and I extracted the lens in a case of hard cataract by Von Graafe's method : I did an iridectomy for an artificial pupil. I resected an elbow joint and excised a large epithelioma. At last I was obliged to let two cases stand over.

"June 6th.—Out-patients in the morning. I made up my mind to finish off the operations which I had no time to do yesterday. Dr. Ross and Dr. Lewer came again. I straightened both knees which were contracted in a young man who had been a soldier in the Maharajah's service. I removed a sequestrum in a case of necrosis of the femur. I did another trichiasis case, and operated on both eyes of an officer's servant for pterygium. At 9 o'clock at night I operated on a case of strangulated hernia."

Towards the end of the year, Dr. Downes performed Symes's amputation at the ankle joint, had a case of occluded os uteri, removed the whole of the lower jaw of a Yorkandi, and tied both thyroid arteries.

A Sure Remedy for Toothache.

AN American homœopathic practitioner states that he has found in the *Plantago major* a sure remedy for toothache. It is, he says, the large-leaved plantain of the door-yard, hitherto known as a nuisance. He gathers it when the rod has grown to full perfection. The leaves are chopped finely, packed closely in a bottle, and covered with strong alcohol for a week. By this time the bright green colour has changed to brown, and it is fit for use. In using it a piece of cotton-wool is saturated with the tincture and inserted in the cavity, and four drops of the same put in half a glass of water, of which a teaspoonful is taken. By rubbing it on the gums, it (on rubbing) was found to ameliorate the painful process of teething ; and when inserted in the ear it is said to be equally efficacious in earache. As there are doubtless many plants of whose medicinal virtues we are perfectly ignorant, and as toothache is one of those torments which often baffle all attempts on the part of the physician to cure it, it may be worth while to give this reputed remedy a further trial, a trial which need not be delayed in the case of such a common complaint as that of toothache.

The Annual Meeting of the Irish Medical Association

Took place on Monday last at the Royal College of Surgeons in Ireland. The day's proceedings were inaugurated by a breakfast of the members at the Shelburne Hotel, which was presided over by Dr. Grimshaw, Chairman of Council, and was largely attended. At 12 o'clock the chair was taken in the council-room of the College of Surgeons by Dr. Nolan, of Gort, who presided in the absence of Dr. Darby, President of the Association, and the report was read by Dr. Chapman, hon. sec. Most of the subjects of special interest to the profession were dealt with by resolutions which, with the observations of the speakers thereon, we hope to give in full in our next issue. The annual dinner of the Association was held in the College of Surgeons, the chair being occupied by Dr. Robert MacDonnell the newly elected President.

The Election of the Council of the Irish College of Surgeons.

THE annual election took place on Monday last in the Board Room of the College. By the resignation of Mr. Butcher and the election of Dr. Wheeler as an Examiner on the Surgical Court, two seats on the Council were vacated. For election to the governing body of the College seven new candidates presented themselves : Dr. Croly, formerly examiner in surgery in the College, Dr. William Elliott, Dr. Jacob, Dr. Thornley Stoker, Dr. Roe, Dr. John Madden, and Dr. J. Bellew Kelly, of Drogheda. The number of Fellows who voted was 112, being a slightly larger number than that of last year. On scrutiny of the poll it was ascertained that Drs. Croly, Elliott, and Jacob had obtained seats on the Council, Dr. Albert Walshe retiring, and all the remaining Councillors being re-elected.

Action of Oxygen Upon Anatomic Elements.

BERT has been studying the toxic action of oxygen under high tension. He finds, by the indirect method of air confined under pressure, that the injurious effect of oxygen upon air-breathing vertebrates begins when its tension corresponds to a pressure of five or six atmospheres. The analysis of the gases contained in arterial blood shows that under this tension the colouring matter of the globules is completely saturated with oxygen, and that gas begins to be dissolved in the sanguine plasma. If the compression is long continued, the solution of oxygen becomes diffused through the tissues, and the organic oxidations are diminished, leading to an immediate reduction of the temperature of the body.

The Sudden Death of Mr. Philip Wykeham Martin, M.P.

THE sudden death of this gentleman in the library of the House of Commons was an event which very naturally created some sensation among the Members who were present last Friday evening. Although he had sat in the House for many years, he was comparatively young, and his death, which arose from disease of the heart, was no doubt accelerated by that fatigue and excitement which would be the inevitable result of his attending to business of any kind. It appears that he was suffering from valvular disease of a decidedly serious character, so that very little exertion or mental excitement would break the slender thread on which his life was evidently hanging. There is, perhaps, no organ of the body which, when diseased, is so much in need of rest as the heart, and yet for obvious reasons there is no organ of the body to which rest is less practicable. The brain can sleep, and the liver, stomach, and other organs are only periodically active; but the heart is at work during the whole period of our existence, and when diseased is, from the complicated nature of its structure, more liable than any other organ to suffer from the effects of either inordinate muscular or mental exertion. A burst of passion, some sudden calamity, hurrying to catch a train, will stop for ever the action of a heart which, if kept at rest as much as possible, might go on beating for years. Patients, therefore, suffering from this painful and terrible disease, cannot be too strictly enjoined to keep themselves continually quiet, and to avoid company as much as possible. Had Mr. Martin done this, his life might probably have been spared, but even his death might be less lamented if it only served as a lesson to others who often undo by their own indiscretion the good they may have derived from the advice of their medical attendants.

Hospital Out-patients' Reform.

THE incidence of charitable medical relief has no doubt become greatly altered since the introduction of the Poor Law Dispensary System amongst us, and it is now high time that the whole question of the work of medical charity in connection with our hospitals was fairly and carefully taken up and more seriously considered. The chief question is, happily, less one of funds than of their injudicious use and administration. The existing income of medical charities would more than suffice if we desisted from the improvident and almost impossible task of providing medical treatment on a purely gratuitous footing for the entire working class and a considerable margin of the lower middle class of society, and extending to medical charity that discrimination without which all charity becomes injurious to the recipients and wasteful to the community.

We are rejoiced to find that managers, and those who administer funds entrusted to them for real works of charity, are beginning to open their eyes to the abuses of hospital out-patients' departments. Sir Sydney Waterlow, who has already evinced a laudable desire to grapple with the evils complained of, announced to the Committee of the Hospital Sunday Fund last week that in a few days a meeting of the treasurers and trustees of the several hospitals would assemble in St. Bartholomew's, with the view of discussing and suggesting a remedy for the abuses of a system which has educated a fourth part of the population of the metropolis into improvident and mendicant habits, and entirely relieved it, as regards this requirement of civilised life, from all necessity for forethought and thrift.

Medical Service in the Paris Exhibition.

THE post of Doctor to the Exhibition has recently been given to Dr. Ladreit de la Charrière, who continues the functions which he discharged during the period of its construction. The service thus organised includes six resident doctors. The principal requirements of the service will be a lecture-room, and an apartment where the medical visitors to the Exhibition will be sure to find all the medical papers, and where they will meet their brother doctors, glad to receive and oblige them.

Analysts in Ireland.

MR. ARTHUR MOORE has procured a return "of all counties in Ireland in which public analysts have been appointed," and of cases in which "specimens of liquor have been submitted for analysis," with convictions and decisions in each case. The secretaries to the grand juries and the town clerks have supplied the information. Every county has an analyst, and most of the greater towns. Dr. Cameron officiates for no less than twenty-seven counties and towns, as well as for Dublin, his salary ranging from £5 per annum, as in Galway and Kilkenny cities, to £50 in Dublin, in addition to £300 in the metropolis. In fact his salaries for making analyses amount to £990 per annum. He analysed in the year four specimens in Derry, four in the Queen's County, 25 in Roscommon, 29 in Waterford city, 1 in Carlow, 8 in Cavan, 14 in Clare, 410 in Dublin county, 46 "chiefly for private persons," in the city; 1 in Fermanagh, 2 in Galway, 4 in Kerry, and 5 in Kilkenny. There were five convictions in the year in the whole island; and from the decisions of the analysts we learn that in general water is the greatest element employed by adulterators. Professor Hodges has five northern counties under his supervision.

The Title of M.D.

A CORRESPONDENT of one of our weekly contemporaries says:—"I take this opportunity of venturing to opine that a great deal of space is allotted to childish whimperings for M.D. from men who had at the proper time not either the steadiness, or their fathers the money, to enable them to graduate." Replying to which criticism the editor complains that those gentlemen who pine for the M.D., cannot "obtain it *under ordinary conditions of graduation*, except by undergoing a part of their education in Scotland or Ireland." "The regulations of the Scotch Universities and the Queen's University," says the editor, "are such as to place the degree of Doctor of Medicine within the reach of the great majority of Scotch and Irish students without any unusual sacrifice of time and money, and without *going beyond the ordinary standard of fair preliminary education* and good medical instruction, such as are attained by the majority of students;" and he complains that the M.D. of the English Universities and the University of Dublin are not to be had as cheaply.

It is not possible to please the general practitioner in this matter without injustice to the university graduate; and we submit that the M.D.s of Oxford, Cambridge, London, and Dublin have a substantial grievance in the fact that the regulations of the Scotch and the Queen's *do* place the doctorate (which has always been the reward for academic culture in a University) at the disposal of students who have not gone beyond the ordinary standard of preliminary education; and we suggest that the *British Medical Journal* should devote itself to the task of bringing these Universities back to the level of their elder sisters, and of removing by this means the anomaly under which England suffers, instead of extending the anomaly to the higher Universities. The *British Medical Journal* is frank in its confession of the reasons for this longing for the M.D. on the part of those who have never taken the trouble to earn that degree. It says: "The degree is valuable in the public mind, and is often important *socially*; and in practice *as being supposed to imply a higher degree of preliminary education.*" This is a perfectly accurate statement of the case; and we venture, thereupon, to ask our contemporary what justification can there be for the Scotch and Queen's Universities granting the doctorate to graduates who never possessed the "higher degree of preliminary education" which the M.D. is "supposed to imply?" and what reason can there be in the "childish whimperings" of men who seek to reap the advantages, "socially and in practice," of a "higher preliminary education," without winning those advantages in the legitimate way?

The granting of the doctorate by the lower Universities to students who have no commensurate preliminary education, is just one of those abuses, born of the greed for graduation fees on the part of those institutions, which the Duke of Richmond's Bill seeks to amend. His Grace is bound by the principle of his measure to secure uniformity in the education required for the degree of M.D., as for all other medical degrees, and he can only obtain that uniformity either by forcing Oxford, Cambridge, London, and Dublin, to give the doctorate to all comers, or by obliging Edinburgh, Glasgow, Aberdeen, and the Queen's University to cease granting the M.D. to any but full graduates in arts.

The General Medical Council has already declared by resolution that the latter course is the only tolerable one, and we do maintain that the Duke will simply act up to the principle of his Bill, and to every principle of equity, if he insists that those who desire the social distinction of a Doctorate in Medicine, shall devote the necessary labour, time, and money to gain it, as it has always been won previously to the creeping in of these degree-selling abuses.

Walking Round the World.

An amateur athlete of Toronto, Canada, named James Duff Henderson, has commenced a pedestrian undertaking of a novel and stupendous nature. He proposes to walk a distance equal to the earth's circumference, and to finish his task within two years, choosing the localities in which to walk, and resting where he pleases. He has walked several days in Toronto, and is now in the United States. Henderson is a fine, stalwart Scotchman, 28 years old, and a house carpenter by trade. He stands six feet in his stockings, and has a stride varying from 42 to 46 inches. He will visit the principal cities in America, and purposes crossing to Europe in time to reach Paris before the close of the Exhibition. He will be accompanied for a time by Dr. Ryder, an hygienic practitioner, who is also one of his backers. He is to receive 50 dollars a month as expenses, and if he succeeds he is to have 10,000 dollars. To accomplish his task by the 1st of May, 1880, he will be obliged to walk 40 miles a day on an average, and he expects to gain enough on this during the first few months to enable him to dispense with walking aboard ship while crossing the Atlantic. We hear that at one or two places he has visited, the public took no notice of the great man, which has rather damped his spirits. Such exhibitions are tedious and worthless, and we hope he will meet with a similar reception here.

Coroners and the Causes of Death.

Scarcely a week passes without our having some proof of the necessity of regulating the action and duties of coroners with a little more precision than that which now obtains. Sometimes, through the medium of some local or provincial newspaper, we have complaints made of the coroner holding more inquests than necessary, and of thus putting the parish to unnecessary expenses. At other times, as the following incident will show, a person dies suddenly under extraordinary or suspicious circumstances and is allowed to be buried without any certificate as to the cause of death. Between nine and ten on Tuesday week, a middle-aged widow, named Whitlam, residing at Sugar's Yard, Gainsborough, died suddenly. She was employed at Mr. Bettinson's osier beds, on the Notts side of the river, and, during a wordy quarrel with another woman, she became excited, and suddenly fell down. A rattling was heard in her throat, she exclaimed, "Lord have mercy on my poor lad," and expired immediately. Dr. Armstrong was promptly summoned, but, of course, his service were of no avail. The circumstances were reported to the coroner (Mr. C. S. Burnaby), who thought that an inquest would not be necessary, notwithstanding that Dr. Armstrong refused to certify as to the cause of death.

It is difficult to form from a short report in a newspaper a correct opinion of such cases as these. Apparently the peculiar circumstances under which the woman died, and the fact that the doctor refused to give a certificate, called for a post-mortem examination and inquest. At all events, it is to be hoped that before long the legislature will make some alteration in the law respecting the holding of coroners' inquests, so that the circumstances under which a coroner should or should not hold an inquest may be more exactly defined, and that not so much should be left to the discretion of that officer.

Swimming and the Disaster in the Channel.

There is one point connected with this terrible disaster, and one lesson to be drawn from it, on which it is quite within our province to make a few remarks. If swimming were not one of the healthiest exercises that can test strength of muscle, soundness of lungs, and power of endurance, we might let the event pass without further notice. But the recent foundering of the German ironclad, two or

three miles off Dover, shows that as a means of saving life swimming is one of the most useful of all athletic sports. The ironclad was only a few miles from shore, the weather was not very rough, and assistance was not far off. Therefore had the whole of her crew been sufficiently good swimmers to keep themselves afloat for an hour or two in the water, probably scarcely one life, instead of 350 lives, would have been lost. *Apropos* of this distressing event, we may notice the excellent letter that Capt. Webb has just addressed to the *Standard* newspaper.

In the recent debate in the House of Lords, swimming is mentioned as one branch of athletics in which candidates for commissions in the army will be tested ; and it appears that the test will be to swim a certain distance in a given time. "I would, however," remarks Capt. Webb, "call public attention to the fact that swimming should be regarded from one main point—viz., as a means of saving human life. From this all-important point of view, I would suggest that the best swimmer is not necessarily the one that can swim the fastest for a short distance, but the one that can keep afloat the longest. The late wreck of the *Eurydice* is one of the many cases that confirm this view. In case of shipwreck the man who finds himself struggling with the waves has to think not so much of reaching shore—too often an absolute impossibility—but of keeping himself afloat with the chance of being picked up by some passing vessel."

Few will dispute the justness of these observations, the truth of which is even better illustrated by the disaster in the Channel than by the wreck of the *Eurydice*, as in the former case the sea was not very rough, and there was time enough for all hands to take to the water. There can be no doubt that in all kinds of sports and athletic exercises, power of endurance is more to be prized than a mere temporary exhibition of speed or muscular strength. On this subject we had much to say when noticing Gale's pedestrian feats, and we shall therefore only now remark that the same power of endurance which in his case could be turned to very little account might in the case of swimmers be the means of saving many thousands of lives. Capt. Webb further writes to say that "with a view of showing how long it is possible for a healthy man to keep afloat, I have determined to attempt a thirty-six hours' swim in the sea on the same conditions as I swam the Channel—viz., no artificial dress, and not to touch any boat, &c. Should I succeed in my attempt I believe some good may arise, inasmuch as the fact that a man had swam for such a length of time might encourage others, who may one day be dependent for their lives on their ability to keep afloat." Very bravely said, and we earnestly hope that Capt. Webb will not injure his health through undertaking a task which seems quite beyond the powers of the human frame to accomplish.

A Special Religious Service for the Profession.

On Friday evening last a special service took place at St. Paul's Cathedral for medical men, organised by the Guild of St. Luke the Physician and Evangelist, and of which Dr. Meadows is the Provost. The objects of the Guild are stated to be to promote and defend the Catholic Faith, especially amongst members of the medical profession, by frequent and regular communion, intercessory prayer, personal influence, and the promotion of works of mercy. The Guild itself is composed chiefly of students and practitioners of medicine, together with a body of clerical associates.

The service was well attended, the ladies largely preponderating; and the musical arrangements were conducted by the London Gregorian Choral Association. It commenced with a processional hymn sung in unison by a numerous choir of men and boys, accompanied by a band of wind instruments, the special psalms and Magnificat being chanted, and accompanied by the strains of the fine organ of St. Paul's, played by Dr. Stainer, and a sermon preached by the Rev. G. Body, a well-known missionary preacher, brought an impressive service to a close. A good deal of care had evidently been bestowed by the Guild on the arrangements of the evening, which were most unexceptionable, and our acknowledgments are due to Dr. Meadows and his professional friends, who were at so much pains to inaugurate so good and novel a service.

The Mortality in Dublin.

According to the Registrar-General's latest returns, the death-rate of Dublin is 33·4 per 1,000 of the population—London ranking for only 20·1, Glasgow for 22·8, and Edinburgh 20·1. The small-pox deaths of the week ending May 25 were 6 less than those of the previous week, but 3 over that of the penultimate week. The cases in hospital are about the same in number (267 against 270), but the admissions are 12 less than those of the previous week. The total deaths of the city are 57 (nearly one-third) in excess of the average.

Ye Ancient Apothicarye.

It may be of interest to the pharmacist of to-day, to know what was expected of the apothecary of a few hundred years ago. Some of the rules would prove fitting examples for the guidance of many a modern pharmaceutist.

The apothecaries of the Elizabethan era compounded their medicines much as medicines are compounded at the present, and the shop customs have undergone only a slight change. The apothecaries' table of weights and measures, still in use, was the rule in the sixteenth century, and the symbols (for a pound, an ounce, a drachm, &c.), remain at this day just what they were 300 years ago.

William Bulleyn, one of the most celebrated physicians under the reigns of Edward VI., Mary, and Elizabeth, and who died in 1576, gave the following golden rules for an apothecary's life and conduct :—

THE APOTHICARYE.

1. Must fyrst serve God, forsee the end, be clenly, pity the poore.
2. Must not be suborned for money to hurt mankynde.
3. His place of dwelling and shop to be clenly to please the sences withal.
4. His garden must be at hand with plenty of herbes, seedes, and rootes.
5. To sow, set, plant, gather, preserve, and kepe them in due tyme.

6. To read Dioscorides, to know ye natures of plantes and herbes.
7. To invent medicines to chose by coloure, tast, odour, figure, &c.
1. To have his morters, stilles, pottes, filters, glasses, boxes cleane and sweete.
9. To have charcoles at hand, to make decoctions, syrups, &c.
10. To kepe his cleane ware closse, and cast away the baggage.
11. To have two places in his shop—one most cleane for the phisik, and a baser place for the chirurgie stuff.
12. That he neither increase nor diminish the phisician's bill (*i.e.*, prescription), and kepe it for his own discharge.
13. That he neither buy nor sel rotten drugges.
14. That he peruse often his wares, that they corrupt not.
15. That he put not in *quid pro quo* (*i.e.*, use one ingredient in the place of another, when dispensing a phisician's prescription), without advysement.
16. That he may open wel a vein for to helpe pleuresy.
17. That he meddle only in his vocation.
18. That he delyte to reede Nicolaus Myrepsus, Valerius Cordus, Johannes Placaton, the Lubid, &c.
19. That he do remember his office is only to be ye phisician's cooke.
20. That he use true measure and waight.
21. To remember his end and the judgment of God; and, thus do I commend him to God, if he be not covetous or crafty, seeking his own lucre before other men's help, succour and comfort.

The Harvey Tercentenary.

On Saturday evening last a festival banquet in honour of the three hundredth anniversary of the illustrious Harvey was given by the President and Fellows of the Royal College of Physicians. Invitations were sent to the members of Her Majesty's Government, the leaders of the late administration and of the medical and scientific professions. The chair was occupied by Dr. Risdon Bennett, F.R.S. (president), and the vice-chairs by Dr. F. Farre (Treasurer), Dr. Pitman (registrar), and the four censors, Drs. Quain, Fincham, Barnes, and Martin. After the usual loyal and patriotic toasts had been duly honoured, the Marquis of Ripon, in responding to the toast of the House of Lords, touched upon the subject of medical education, giving it as his opinion that it was necessary both for the sake of the profession and the public that the whole question should be legislated for in a liberal and comprehensive spirit, as an earnest of which he deemed the readiness of the Lord President to incorporate the compulsory conjoint scheme into his Bill an excellent omen. To Professor Huxley the honour of replying to the toast of the evening, "To the Honour of Harvey," was entrusted, than which a better choice could scarcely have been made. Mr. Gladstone, Mr. Lowe, Dr. Quain, Dr. Allen Thomson, Professor Michael Foster, and others spoke during the evening, the whole affair passing off in the most brilliant and satisfactory manner, reflecting the greatest credit upon the officials and all concerned in the management.

Fears having been expressed as to the water supply at Malta being equal to the demand made upon it by the increased garrison, orders have been sent out for two powerful condensers in the dockyard to be prepared for the service of the troops should any scarcity be threatened.

Mr. Parnell is highly incensed against Dr. Burns, who brought the convict Reddin to his senses, with the aid of an electric battery, when shamming fits before the judge, and moved in supply in the House of Commons last Thursday, that the vote for convict establishments be reduced by £450, the amount of the doctor's salary. In a House numbering 231 members, Mr. Parnell could only gain the sympathies of 18, and Dr. Burns will get his salary, notwithstanding that Mr. Parnell prefers malingering to galvanism in convicts.

The County Infirmaries (Ireland) Bill was, on Wednesday last, again postponed to the 9th June. This measure has been most unfortunate in its career; in 1876 it was introduced, but met the fate of many other "slaughtered innocents." Again this year the second reading was postponed, and now the promoter (Mr. Meldon), when the time arrives, is not prepared to proceed, not having the Bill printed.

An application was made on Saturday last to set aside the judgment in the Bagot will case, about which there was so much conflicting medical evidence on the ground of misdirection by the judge, and that the verdict was against the weight of evidence. The motion was postponed indefinitely in consequence of the great pressure of other cases.

Small-pox seems steadily declining in London; last week the deaths from this cause were 43. Of these, 23 were certified as unvaccinated, 4 vaccinated, the remaining being uncertified as to vaccination. In Dublin there were 15 deaths from small-pox, but not one in any of the large provincial towns in the United Kingdom was reported.

In the principal foreign cities, the last weekly returns of mortality per 1,000 of the population were:—St. Petersburg 64, Calcutta 52, Buda-Pesth 46, Alexandria 41, Bombay 39, Naples 39, Vienna 35, Munich 33, Stockholm 30, Turin, Dresden 29, Rome, Berlin, Geneva 28, Amsterdam 25, New York 24, Paris 23.

We are glad to notice that at the last election of the important metropolitan district of St. Marylebone, Dr. McGrigor Croft, of St. John's Wood, was carried in at the head of the poll for No. 2 Ward, as guardian of the parish.

The mortality last week in the four principal cities of the United Kingdom, was again low, except in Dublin. In London it was 20, Edinburgh 21, Glasgow 23, and Dublin 33 per 1,000 of the population. The large towns in the second category were exceptionally healthy.

Literary Notes and Gossip.

We understand that within a few days the report of the Copyright Commission will be laid before Parliament. The opinion of the majority of the Commissioners is that copyright should last for the author's life and for thirty years after, their reason being that this is the period allowed on the Continent, and that by assimilating our own practice to tha

of other nations, a step, at any rate, will be taken towards the establishment of international copyright. What recommendations will be made with regard to the vexed question of international copyright itself is not certain. The matter is a difficult one, and cannot be properly approached, unless we recognise that literature, like all other professions and occupations, is governed by the stern laws of supply and demand. As the matter at present stands, America has undoubtedly the best of English authors; she can pirate any English book she chooses, and to protect such piracy she fixes very high customs duties upon all English imported books. True, she says we can do the same, well knowing that with few exceptions she has produced no works worth a publisher's attention. Yankee cuteness is all very well in its way, but we would rather recognise in our brothers on the other side of "the herring pond" a little scraping of that Divine principle of "doing unto others as they would men should do unto them."

* * *

We understand that Mr. Fleming, author of "Rabies and Hydrophobia," "Text-book of Veterinary Obstetrics," &c., is engaged upon another large work entitled a "Text-book of Comparative Pathology (General and Special) and Therapeutics." Mr. Fleming's great literary abilities and research warrant us in looking forward to an original and comprehensive contribution to our pathological knowledge.

* * *

Mr. Balmanno Squire has decided upon a re-issue of his atlas of Skin Diseases, which was first published in 1864, in an altered form. The first part has appeared this week as a demy 8vo, with text and four plates lithographed in colours.

* * *

The greatest satisfaction is expressed in literary and scientific circles by the selection of Dr. Brown-Séquard, as successor to the illustrious Claude Bernard in the College of France. Dr. Brown-Séquard's attainments are too well known to need recapitulation here, and being personally known to the profession in America, France, and England, having both English and French blood in his veins, the choice will be widely popular.

* * *

At the last meeting of the Royal Irish Academy, Dr. Aquilla Smith, representative of the King and Queen's College of Physicians in the General Medical Council, was awarded one of the massive Cunningham gold medals for his writings in "Numismatics." A medal was also awarded to Dr. Allman for his biological researches.

Correspondence.

THE PURIFICATION OF WATER.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—We need not have taken any notice of the remarks by the Secretary of the London and General Water Purifying Company in your issue of May 22nd, if the general public were not apt to be misled by such incorrect statements when brought forward with some degree of boldness. By referring to Professor Bischof's paper, read before the Society of Arts, of which we enclose a copy for your perusal, it is easy to show that your correspondent's assertions are throughout inconsistent with truth. He says that the excellence of the Spongy Iron Filter exists only in "the Professor's *own idea*." We have marked in the enclosed copy no less than *eight* official reports which the lecturer quoted as to the unquestionable superiority of spongy iron as a filtering medium for potable water. The sole opinion he himself gave as to this was conveyed by an incidental reference to some physiological experiments of his bearing on water purification.

The remarks about the defects of animal charcoal were likewise based upon quotations from official and other reports. It is singular that your correspondent, in referring to certain obsolete reports about animal charcoal, cannot see that Dr. Frankland quite consistently proclaimed that material—with all its defects—as the most efficient purifier of water at the time when the application of spongy iron for that purpose was unknown. But like everyone who is unbiassed, he was compelled to acknowledge the superiority of the latter material after the exhaustive experiments which he officially made as to its merits. Again, the lecturer's remarks about the renewal of animal charcoal in filters are not his own, but, as stated expressly, extracted from official evidence.

The "chalybeate" character of the water from spongy iron filters exists only in your correspondent's too vivid imagination. Your space is too valuable to allow of any lengthy explanations, but we shall be glad to forward to any one of your readers such evidence as to this point as will set his mind at rest.

We prefer that the spongy iron filter should stand on its own merits, but since your correspondent has provoked criticism, we may tell him that Professor Bischof seems singularly well informed on water filters. Speaking about the usual construction of cistern filters, he said: "Unless the top is jointed perfectly tight, the unfiltered water, with upwards filtration, may be sucked in through the joint, without passing at all through the materials." Now it so happens that since the paper was read a gentleman wishing to exchange one of the London and General Water Purifying Company's cistern filters for a spongy iron filter, and to employ the former for mechanically straining the water not used for drinking, sent it to be charged with sand. On testing it by immersion in water, we found that the defects referred to by the lecturer applied in a marked degree to this filter; in fact, on account of the leakage through the joint, the London and General Water Purifying Company's filter proved useless, even as a mechanical strainer.

We remain, Sir, your obedient servants,

The Spongy Iron Water Purifying Company.

505 Oxford Street, W.C., London, May 27, 1878.

THE FORTHCOMING ARCTIC EXPEDITIONS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—The recent article in the Medical Press on the above subject has been extensively reprinted and quoted in various newspapers and journals, the *Yorkshire Independent*, the *West Central News*, the *Echo*, the *Alliance News*, and the *Temperance Record*, amongst others, giving prominence to the Medical Press "Current Topic" on the question of alcoholic stimulants in Arctic exploration. The article having been transferred in its entirety to the pages of the *Temperance Record*, has elicited a communication from Captain Wiggins, "The Elms, Sunderland," in which that experienced and well-tried Arctic voyager commends your suggestion of a total abstaining ship's crew; and so much confidence has he in the success of the trial, that he offers to take the management and command of such a ship, having been already engaged in three expeditions extending over four seasons, during which his "men grew fat and flourished on total abstinence." Capt. Wiggins further says: "I have never yet taken spirits of any kind whatever to sea in these expeditions; and that during a "severe winter journey of over 8,000 miles of sledging, night and day, at the highest speed possible, covering for days together 200 miles per day, I not only never needed such a thing as false stimulants, but demonstrated in the most striking manner the fact that they were most injurious." A gentleman who travelled with Captain Wiggins, "a most abstemious man," acclimatised to the severities of a Siberian winter, was knocked up before he had accomplished half the journey, although he and the captain occupied the same sledge—but this abstemious gentleman was not an abstainer, and hence he could not resist the influence of the climate which his companion so easily withstood. Eventually, however, a medical gentleman prescribed total abstinence to the sufferer, and then he too was untouched, and went on his way rejoicing.

The above is the merest abstract of Captain Wiggins's interesting letter; but I presume enough has been quoted to convince the most sceptical that the only safe course in the colder regions of the globe, at all events, is abstention from what Captain Wiggins emphatically calls "the *pernicious* influence" of alcoholic stimulants.

As the subject is a strictly medical one, as well as of national interest, I have ventured to ask your permission to ventilate it in the columns of the Medical Press, especially

as the medical aspect of the temperance question is now so generally recognised by the Profession, and Dr. Carpenter's oration before the Medical Society of London is receiving ample justice at your hands by being published in your columns.

Faithfully yours,

H. P. G.

Poland Street, W.

Medical News.

Royal College of Surgeons of England.—The following gentlemen, having passed the required examinations, received the diploma of M.R.C.S. at a meeting of the Court of Examiners on May 23rd :—

Andrews, W. Stratford, Dover.
Apthorp, F. William, Lee, Kent.
Bisdee, James, L.S.A., Hutton, Somerset.
Buckle, John, L.S-A., Catton, Norwich.
Butler, G. William, Abingdon.
Candler, W. John, Harleston, Norfolk.
Clark, J. R. Andrew, L.S.A., Cavendish Square.
Clitherow, R. Edward, L.S.A., Horncastle.
Crouch, E. Thomas, L.S.A., Devonport.
Edwardes, W. Whitfield, L.S.A., Llansantffraid.
Fulton, James, M.D. Toronto, St. Thomas, Canada.
Good, F. Thomas, L.S.A., Highbury Hill.
Hawkins, Howard, Lee, Kent.
Jackson, Thomas, L.R.C.P.Ed., Great Torrington.
Ling, M. Edward, L.S.A., Saxmundham.
Shaw, George, L.S.A., Blackheath Park.
Smith, K. Rawlings, L.S.A., Stamford Hill.
Snowden, G. Hugh, Ramsgate.

Ergot in Diabetes Insipidus.—The *Philadelphia Reporter* says that Prof. Da Costa's clinic on January 12th exhibited a patient who had been passing ten pints of urine daily, the amount of fluid ingested being fully two pints less. No cause could be assigned for the disease. The urine contained no sugar or albumen, and had a s.g. of 1,005. When commencing the use of ergot, drachm doses of the fluid extract were taken three times daily, then four times, and at last six times daily. The effect on the renal secretion was to reduce its amount to five pints, then to three pints, by which time the ergot had been stopped and peppermint water substituted. During two weeks of this supplemental treatment there was no return of the disease. Prof. Da Costa has had three other cures by this method, one of which was verified a year after its discharge.

The Hospital for Consumption, Brompton.—On Thursday last Lord Derby presided at the annual court of the governors of the Hospital for Consumption, Brompton. In moving the adoption of the report, the noble lord referred to a prevailing impression that the institution was so largely endowed as to be independent of donations and subscriptions, and pointed out that the real fact was they were dependent upon the public to the extent of four-fifths of their income. The report of the committee of management stated that there were 1,222 in-patients during 1877 ; of these, 891 had been discharged, 137 had died, and 194 remained in the hospital on Dec. 31, 1877. The receipts were £19,766 5s. 9d., and the expenditure £18,097 15s. 8d. The income showed a falling off, though, happily, the expenditure had been more than covered by the receipts from all sources. The committee hoped that before another annual court much progress would be made with the new building for the extension of the hospital.

Poplar Hospital for Accidents.—The twenty-third annual festival of this institution was held on Friday last at the City Terminus Hotel, under the presidency of Sir W. J. Baynes. The hospital, which is contiguous to the docks, warehouses, engineering and manufacturing establishments of the port of London, is in the midst of a densely-crowded population. The number of patients relieved during the past year was 4,881. The chairman, in proposing "The Poplar Hospital," said that the founder had purposely placed it near the dock gates, where accidents were of constant occurrence. It was not at all local in its scope, and would be better named as the "Port of London Hospital." Having no endowment and but little invested capital, it had to look for the £4,000 it required annually to a benevolent public, to whom, through his hearers, he now appealed.—During the evening the secretary read a list of subscriptions amounting to £1,800.

The Victoria Hospital for Children, Chelsea.—The annual dinner of this charity, which was established in 1866, took place on Wednesday last at the Grosvenor Gallery, New Bond Street, the Earl of Cadogan presiding. After the various toasts had been honoured, it was announced that the donations and subscriptions promised that evening amounted to £900. Funds are urgently required to pay the balance of the purchase money of additional land, and also for recent repairs and current expenses. Seventy beds are maintained at the institution, sixty at the hospital, and ten at the convalescent branch at Margate.

London Temperance Hospital.—Lord Aberdare presided at the Memorial Hall on Friday last at the annual meeting of this hospital, which was founded some five years since, to demonstrate that the non-alcoholic principle of treating disease and injuries is scientifically sound. During this period 600 in-patients and 6,000 out-patients have been treated, with results which are declared to be wholly confirmatory of the principle on which the institution was started. The chairman in opening the proceedings said that it was well known that he could not see his way to support a measure for the total abolition of the liquor traffic or of liquor drinking ; but he gave his most attentive and favourable consideration to the efforts of that hospital to establish what he thought would be a great and most important principle, and his most hearty sympathy and support to any attempt to diminish the horrible and monstrous evil of intemperance. Judging from the figures in the report of the hospital, its results were admirable, but he still wanted further evidence before he could agree with the main proposition, that all diseases can be treated in all cases as successfully without alcohol as with it.—Cardinal Manning, who proposed a resolution of thankfulness at the success of the hospital, referred to his having incurred the displeasure of an eminent physiologist by declaring some time since that the medical faculty owed reparation to the public for the countenance given in past years to the use of intoxicating liquors. If he repeated the charge it would be not on his own authority, but under the shelter of such names of Dr. Richardson, the two Drs. Carpenter, and Dr. Wilks of Guy's, which would protect what he said from any appearance of animosity against a distinguished profession. What he meant was that a quarter of a century ago it was thought necessary to use stimulants in the great majority of cases where there was debility, and it was perfectly certain that drinking habits, of which hundreds of cases had come under his own cognisance, had been formed by following medical advice. Dr. Edmonds, in response to the query of the chairman, gave as the result of his experience that such cases could be dealt with without the use of alcohol, by the employment of the ice cap and such remedies as opium and chloroform.

A Study of Muscular Physiology.

Prof. Coutance, of Brest, has recently called attention to the advantages presented to physiologists by acephalous mollusca, especially *Pecten maximus*, for analysing the most interesting and delicate phenomena of muscular action, without having recourse to the apparatus at present employed. Experiments may be made on the animals and muscles intact, so that the complications connected with vivisection are avoided. The *Pecten maximus* has an enormous adductor muscle of about 26 grammes weight placed between two movable levers, the valves, whose movements manifest those of the muscles itself, and may be amplified by means of a long needle attached to one of the valves ; thus muscular contractions and elongations of fractions of a millimètre may be translated into centimètres on a scale. M. Coutance has made many experiments of this kind, trying the effect of various stimuli, anæsthetic agents, &c. Among other things, he has been able to prove that certain fibres of these adductor muscles are designed to bring back the valves, others to retain them. He has also tested the muscular strength of a number of common acephala, referring it to unit of surface, the square centimètre.

NOTICES TO CORRESPONDENTS.

☞ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber,' "Old Subscriber," &c. Much confusion will be spared by attention to this rule

READING CASES.—Cloth board cases, gilt-lettered, containing 26 strings for holding each volume of the MEDICAL PRESS AND CIRCULAR, can now be had at either office of this Journal, price 2s. 6d. The postal regulations not allowing the Journal to be stitched, these cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

NOTICE TO SUBSCRIBERS.—Subscribers who have not already paid their subscriptions for last year are reminded that they are now due and should be sent to the publishers, who will be happy to acknowledge their receipt.

A SUFFERER.—Prof. Menière's "Electric Alarm for Prevention of Night Emissions" can now be had in this country of Messrs. Holdernesse and Co., Instrument Makers, 16 Corporation Street, Manchester.

KRYOLITH.—We have been asked by one or two correspondents what this word means. It would probably be better understood if spelled "Crolyte." It is a fluate of soda and aluminium, a rare mineral, found chiefly in Greenland.

PROF. T. SPENCER WELLS will commence a course of six lectures at the Royal College of Surgeons of England on June 10th on "The Diagnosis and Surgical Treatment of Abdominal Tumours." On the 24th Mr. B. T. Lowne will also commence a course on "The Physiology of Nerve Stimulation." With these latter lectures the annual courses at the College will conclude.

UNGUENTUM PETROLEI.—Under the head of "Novelties" in our last, we referred to this substance as being a very valuable addition to our stock of pharmaceutical products. We, however, omitted to mention the names of the agents for the United Kingdom, which we now supply. They are Messrs. Allen, Hanbury, & Co., Pough Court, Lombard Street, London; Dr. J. Evans, Dawson Street, Dublin; and Messrs. Duncan & Flockhart, Edinburgh.

MR. L. B.—By all means.

DR. T. W. E.—It is our intention to refer to the subject in our next.

A COUNTRY PRACTITIONER.—You acted with perfect propriety under the circumstances. Your friend should invest a shilling in "Rules of Medical Etiquette," by a Licentiate of the Royal College of Physicians.

ON BLOOD-LETTING AS A THERAPEUTIC.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—It must prove a difficult task at times for your compositors to copy into type from my cramped writing. My letter on "Blood-letting" in last number is, therefore, rendered with fair accuracy, but to make the sense better, I must ask you to note that "in" in the second line of first column, after "concerned," should be "as;" "pleuritis" before "with convulsions," at top of second column, should be "phrenitis;" "intermittingly," about middle of same column, should be "unsparingly;" and lastly, "hæmorrhagia" should read "menorrhagia."

This done, I wish to claim a small space from you at present to say that, in response to your article on "Counter-prescribing," I do most willingly set down my guinea in aid of the funds of the Defence Association, an early member of which I have been and still am a member.

The argument has been plainly placed before the profession now in your pages on grounds from highest to lowest, and if to save themselves in many pounds medical men refuse to contribute shillings, I think such conduct can be expressed by only two words—*beggarly* and *idiotic*. Can another word be said?

I am, Sir, respectfully yours,
Houghton-le-Spring, Durham, J. O'FLANAGAN, L.R.C.P.Edin.
May 30, 1878.

SANITARY INSPECTION.—An Association has been started in Manchester under the title of "The Manchester and Salford Sanitary Association," for the purpose of providing its members at a fixed cost with sanitary and engineering inspection of their own houses, and the inspection and improvement of the dwellings of the poor. If it be what it professes, a *bonâ fide* Association to remedy existing evils, and not a mere commercial speculation, we wish it every success. At present no names appear on the prospectus, we are, therefore, unable to pass an opinion.

PELVIS, if doubtful about the forms of contraction of the pelvis, should seek the advice of a consultant. If determined upon the use of the flexible catheter, he should insert it carefully within the uterus. It is a matter of no importance into which part of the cavity of the uterus it finds its way, but no force sufficient to injure the placenta should be employed. It may be left two or three days, or if signs of labour do not show themselves, may be removed and re-inserted.

M.D., Lincoln.—The report came to us too late for comment in the present number; we shall refer to it in our next.

THE ATTEMPTED ASSASSINATION.—We are glad to be able to report that the Dr. Nobiling who so treacherously attempted the life of the German Emperor, is not a member of the medical profession, but a Doctor of Philosophy of the University of Leipsic.

MR. HAY.—Thanks: if space permits we will utilise it in our next.

APPOINTMENTS.

BURTON, S. H., M.B., M.R.C.S.E., Surgical Registrar to University College Hospital.

CLARKE, J., M.D., C.M., L.M., Junior Resident Surgeon to the Belfast Royal Hospital.

DENSON, J. L., L.K.Q.C.P.I. & L.M., a House Surgeon to the Royal Infirmary, Liverpool.

FAULKNER, A. S., M.R.C.S.E., L.R.C.P.I., a House Surgeon to the Royal Infirmary, Liverpool.

HODGSON, G. G., M.R.C.S.E., a House Surgeon to the Royal Infirmary, Liverpool.

HOGGAN, G., M.B., C.M.Edin., an Hon. Medical Officer of St. John's Hospital for Diseases of the Skin.

O'DONAGHUE, P., L.R.C.P.Ed., L.F.P.S.G., Medical Attendant to the Royal Irish Constabulary, Loughrea, co. Galway.

O'NEILL, H., M.D., C.M., L.M., Senior Resident Surgeon to the Belfast Royal Hospital.

POPE, F. A., M.B., L.R.C.S.I., Surgeon to the Throat and Ear Hospital, Dublin.

ROSE, J., M.R.C.S., House Physician to the Royal Infirmary, Liverpool.

TAYLOR, S. T., M.B., L.R.C.P.L., M.R.C.S.E., Medical Officer of Health for the St. Faith Rural Sanitary District, Norfolk.

THORNLEY, J. G., M.D., Assistant Medical Officer to the Wilts Lunatic Asylum, Devizes.

TWINEM, J., M.R.C.S., House Physician to the Royal Infirmary, Liverpool.

WILKINS, R. B., M.R.C.S.E., a House Surgeon to the Metropolitan Free Hospital.

WINTER, W. H. T., L.K.Q.C.P.I., a House Surgeon to the Metropolitan Free Hospital, Dumbleton.

Marriage.

THOMSON—WALKER.—May 27, at the Church of St. Martin's-in-the-Fields, London, James Archer Thomson, M.B. & C.M., Jersey, to Charlotte, second daughter of the late Robert Walker, of Stratford-on-Avon.

Deaths.

BRUCE.—On May 17, at Great George Square, Liverpool, David Herd Bruce, M.B., aged 29.

BRUCE.—On May 8, at Loch-Inver, Sutherlandshire, James Bruce, L.F.P.S.G., aged 23.

FRAZER.—On May 26, at Nottingham Terrace, Regent's Park, Thomas Frazer, M.D., R.N. Retired Deputy General-Inspector of Hospitals and Fleets, aged 72. Friends will kindly accept this intimation.

GRANT.—On May 10, at Clarendon Villa, The Hyde, Hendon, William Grant, M.D., R.N., aged 38.

HAMILTON.—On May 28, at 2 Honor Oak Park, Forest Hill, Mark Hamilton, M.D., R.N., Staff Surgeon, aged 63.

HEFFERNAN.—On May 29, at Ballyvoreen, co. Limerick, James Heffernan, M.D., aged 72.

HEWARD.—On May 28, at Clare, T. Spencer Heward, L.R.C.P.Edin., late of 56 Grosvenor Street, London, and of Langley, Bucks, aged 64.

HILL.—On May 30, at Earl's Court House, Old Brompton, Dr. R. G. Hill, F.S.A., aged 67.

MURTAGH.—On May 11, at Gort, co. Galway, James Walsh Murtagh, M.D., aged 25.

STEVENSON.—On May 27, Thomas Stevenson, L.R.C.P.Ed., of Iver Heath, Bucks, aged 77.

IRISH POOR-LAW INTELLIGENCE.

MEDICAL WITNESSES AT ASSIZES AND QUARTER SESSIONS.

THE following is the copy of a circular sent to the several benches of magistrates in Ireland under date of 15th May :—

"Dublin Castle.

"GENTLEMEN,—The attention of the Lord-Lieutenant has been called to the great and unnecessary expense of medical witnesses at assizes and quarter sessions, and as there is reason to believe that such witnesses have recently, on several occasions, been somewhat unnecessarily summoned and examined when their evidence might readily have besn dispensed with without detriment to the administration of justice, I am directed by his Grace to impress upon you the necessity of exercising great caution in the matter of summoning and binding medical witnesses to appear at assizes and quarter sessions, unless in important cases, or where it can be satisfactorily shown that such evidence is indispensable for rightly disposing of the case. His Grace desires me to remind you that if it should afterwards become essential to produce a medical witness in order to sustain the charge for which the accused may be indicted, there will be no practical difficulty in procuring the attendance of such medical witness by Crown summons at assizes or quarter sessions.

"I am, Gentlemen, your obedient servant,

"T. H. BURKE."

LIMERICK URBAN SANITARY BOARD.

DUTIES OF CONSULTING SANITARY OFFICERS.

A report was read from the Relieving Officer stating that he prosecuted two cases at the last petty sessions, but the magistrates dismissed the cases on the ground that it was shown the house had surface drainage and that the yards were kept clean. Dr. Barry refused to give evidence, as he had not been summoned and was not paid, but Dr. Holmes did give testimony.

Dr. Barry held that he was only bound to attend the meeting of the board and consult with the members as to the proper administration of the Sanitary Acts. The sanitary officer should attend when required by the executive officer.

After some discussion the following minute was made: —"That the Local Government Board be furnished with a copy of the report as a reply to their letter of the 15th inst. This board wished to explain that even had Dr. Barry given evidence his testimony could only be a repetition of Dr. Holmes's evidence. But the cases were dismissed on the grounds that under the circumstances it was proved that there were open sewers sufficient to keep the yards clean."

[Dr. Barry was perfectly right. The duties of the Consulting Sanitary Officer, as set down in the general order of the Local Government Board, are as follows :—"The duty of the Consulting Sanitary Authority shall be to attend meetings of the guardians acting as Sanitary Authority whenever required to do so, and to advise them on all matters and proceedings requiring medical knowledge and advice in the administration of the sanitary laws." Nor is it the duty—according to the Act of Parliament—for the medical sanitary officer to give evidence at prosecutions. The Local Government Board, it is true, has taken upon itself to impose such duty amongst others, by their order that the medical officer "shall attend and assist in all proceedings in which his attendance or assistance may be required ;" but this imposition of duty has no warrant in law, and we trust that it will be set aside in the new Public Health Act.—ED.]

ATHY PETTY SESSIONS.

DUTIES OF VACCINATORS.

THE court was crowded to inconvenience, principally by women with children in their arms, who were summoned by the Athy board of guardians as alleged defaulters under the Vaccination Act.

The first case called was Mr. Kelly. Mr. Cooper, relieving officer, prosecuted on behalf of the board of guardians.

The defendant handed to the bench the legal certificate of successful vaccination, from which it appeared the child had been vaccinated within the time required by the Act —six months.

Mr. Cooper said all the defendants had been served with a printed circular, calling on them to have their children vaccinated, and informing themt hat if they did not comply legal proceedings would be instituted against them under the provisions of the Compulsory Vaccination Act, to which a note was added :—"When you shall have complied with the request herein contained you will please notify the fact at once to me.—JAS. COOPER."

The defendant questioned the right of the relieving officer to require such a notification. The fact of the child having been successfully vaccinated should be properly registered by the medical officer, and if such were done, and a proper examination of these books made, there would be no necessity to summon and keep from their business people who had complied in every respect with the Act.

The Chairman having consulted the Act, said he could not see that the parents or guardians were required to give such notice. It was perfectly plain that it was the duty of the medical officer to duly register every case of successful vaccination. Section 3, cap. 52, of the Compulsory Vaccination Act says :—"Upon and immediately after the successful vaccination of any child the medical officer or practitioner who shall have performed the operation shall deliver to the father or mother of the said child, or to the person who shall have the care, nurture, or custody of the said child, a certificate under his hand, according to the

form of schedule hereinafter inserted marked A, that the said child has been successfully vaccinated, and also transmit a duplicate of said certificate to the registrar of births and deaths of the district in which the operation was performed, and such certificate shall, without further proof, be admissible as evidence of the successful vaccination of such child in any information or complaint which shall be brought against the father or mother of the said child, or against the person who shall have the control, nurture, or custody of such child as aforesaid, for non-compliance with the provisions of the Act, provided that if the medical officer of any dispensary district is also the registrar of the district, it shall be sufficient for him to sign one certificate to be delivered to the father or mother or other person as aforesaid, and to register the fact of such vaccination in the manner hereinafter prescribed." The Chairman then said —Nothing can be plainer or more distinct than that, and certainly these people who have complied properly with the Act should never have been brought here by the board of guardians. It is clearly the duty of the doctor in all cases of successful vaccination to register them. Whoever the medical officer was in whose time these cases occurred, if he carried out his duties properly some of these prosecutions would certainly never have been brought. The parties holding these certificates have no right whatever to give any notice or send down their certificates. It is the medical officer who is to blame.

The case was dismissed.

In the next case called, it appeared that the child was not vaccinated for some time after the six months had expired. The mother stated that the child had measles, and was not fit to be vaccinated at the proper time.

In reply to the bench, she stated she had not received a medical certificate to that effect from any doctor.

Bench.—On this point, too, the Act is quite plain. It requires the parents or guardians of any child to procure a certificate of its unfitness from a medical officer, which certificate will protect them from any prosecution.

The Clerk of the court said it had been proved in that court on a former occasion that the doctor would not give this certificate.

Bench—We have nothing to do with that now. We are only pointing out what the Act requires. If it is not complied with it is another matter. We hope this point in particular will be publicly known, for a great many of the people seem to be of opinion that if the child is not fit they have nothing more to do. Now it cannot be too strongly impressed on them that they are liable to the full penalty, even although the child may not have been fit, if they fail to provide themselves with a certificate of its unfitness.

Fined 1d. and costs of court.

In the next case called the father swore that the child died within a month of its birth.

The mother swore she registered the birth and death of the child on the same day—the day the child died.

The Chairman—This is a clear case of neglect on the part of some one. It has been positively sworn to that this child's death was registered one month after its birth. Now if that death was entered in the proper registry, why send out a notice several months after to have a dead child vaccinated, and then summon the parents for not having done so? We trust this matter may be closely looked into by the board of guardians, for while we are determined to carry out the law stringently in the case of defaulters—for in future it is our intention to impose the full penalty—we hope the guardians on their part will thoroughly investigate the cause of these irregularities.

The case was dismissed.

In all the remaining cases, of which there were a large number, when it was proved the defendants had not complied with the Act small fines were imposed, but a great number of the summonses were dismissed.

CORONER FOR THE CO. LIMERICK.

It is stated that Dr. Wm. C. Murphy, who for a number of years discharged the duties of coroner with zeal, ability, a courteous disposition seldom equalled, has resigned or is about to resign the office he held. The office is now sought by Dr. Hartigan of Croom, and Dr. McNamara of Bruff, who are both engaged in active canvass amongst the freeholders. The polling is to take place at Bruff, and will continue for two days, and a lively contest is anticipated.

WATERFORD ASYLUM.

At the usual monthly meeting of the Governors of this institution Dr. W. Connonly was elected visiting physician, the voting being—For Dr. Connolly 7 votes; for Dr. Alcock 4; for Dr. Browne 1.

THE KILMALLOCK INSURANCE FRAUDS.

REFUSAL OF THE LOCAL GOVERNMENT BOARD TO SANCTION DR. MEEHAN'S APPOINTMENT.

At the last meeting of the Board of Guardians to-day, the following letter from the Local Government Board was read:—

"Local Government Board, Dublin,
May 21st, 1878.

"Sir,—The Local Government Board for Ireland have had under their consideration the resolution which was passed at the meeting of the Board of Guardians of Limerick Union, on the 15th inst., in the following terms:—'That the consideration of the report of the Local Government Board on the case of Dr. Meehan be postponed for one month, pending the inquiry which we understand is to be instituted in this case in the House of Commons, and that Dr. Meehan be continued in the present employment of the Board of Guardians until we have the decision of the inquiry, as this board has already shown, by their selection of Dr. Meehan, that they believe in his innocence; and we request the Local Government Board to sanction Dr. Meehan's continuation in the office for one month from this date.'

"In reference thereto the Local Government Board have to state that, as the Board of Guardians persist in continuing the services of Dr. Meehan, notwithstanding the refusal of the Local Government Board to sanction his appointment, an order, under seal, will be made removing him from the office to which the Board of Guardians have appointed him.

"The Local Government Board have already stated distinctly the grounds upon which they felt themselves unable to sanction Dr. Meehan's appointment as medical officer, and the terms of the resolution above quoted do not alter the state of the case in any respect. By order of the Board,

"B. Banks, Secretary."

A sealed order, removing Dr. Meehan from the office, was enclosed.

Mr. Cregan said the Local Government Board had treated the mild remonstrance of the guardians in a high-handed and arbitrary manner, and he hoped they would not rest quietly under the indignity. He proposed a resolution remonstrating with the Local Government Board, and earnestly requesting them to reinstate Dr. Meehan in the office.

The motion, on a division, was carried by 23 votes to 9. Eleven guardians declined to vote.

[Although we do not feel it necessary to adopt any definite view of Dr. Meehan's culpability in connection with these transactions, and are decidedly of opinion that deliberate fraud was not proved against him, we feel it to be due to the Local Government Board to say that we do not see that they could, under the circumstances, have

adopted any other course than that pursued by them. They could not be expected to revise the decision of a jury, whether that decision be just or the reverse.—Ed. M. P. & C.

SOUTH DUBLIN UNION.

DESTRUCTION OF INFECTED CLOTHING.

Mr. Shackleton moved that the clothes worn by small-pox patients in the Kilmainham Hospital should be destroyed and other clothing supplied to them. The only effectual way of preventing infection from being transmitted by clothes was to burn the clothes. There was no doubt that the small-pox epidemic had originated from a solitary case of a person who came here from Lancashire. Some months ago the Public Health Committee made an order for the destruction of small-pox clothing. Afterwards they rescinded that order; but they had since seen the necessity of re-enacting that order, and it was now carried out at Cork Street hospital. He believed that if they had adhered to their first resolution there would not be so many cases of small-pox as there were now. The opinion of the highest medical authorities was that the application of heat to the clothes was quite insufficient to destroy the seeds of the disease. His resolution might involve an expense of two or three hundred pounds, but that would be an infinitesimal addition to the rates.

Sir George Owens seconded the resolution. It was a measure essential for the stamping out of infection. The Local Government Board approved of it, and would sanction the expenditure involved.

Mr. James M'Grane, in supporting the motion, said he hoped the expense would be fairly divided between the city and the rural districts.

Mr. Macready said the guardians never hesitated about paying what was necessary for the stamping out of cattle disease, and he would certainly vote for the present resolution, which had the object of saving human life.

Mr. Bentley did no see that the resolution was necessary.

Mr. O'Brien, Local Government Inspector, said there was power to charge for the destroyed clothes under the head of "wear and tear of clothing."

The resolution was carried on a division by 15 to 6.

SUPERANNUATION.

A letter was received from Dr. Henry Croly, medical officer of Rathfarnham Dispensary, resigning his office. Accompanying the letter were communications from Mr. Porter, surgeon to the Queen, and Dr. O'Leary, to the effect that Dr. Croly, who was over seventy years of age, was no longer equal to attending sick calls by night and day.

Sir G. Owens gave notice that on that day five weeks he would move—"That the board grant a superannuation allowance to Dr. Henry Croly of £120 per annum, being two-thirds of his salary, and emoluments for the last five years, he having served for 27 years as medical officer of Rathfarnham dispensary."

DUNGARVAN UNION.

MIDWIVES' ATTENDANCE.

The medical officer reported that a ticket was issued for his attendance on a woman in labour. He was from home, and on attending about four hours afterwards he found no experienced nurse in charge of the case, the matron informing him that she had no authority to send for a nurse. Master said that the woman who attended ordinary cases of midwifery had left the house. There was an order of the board that the medical officer should be called in before the union midwife.

Dr. Hunt.—The doctor is never required in ordinary cases of midwifery.

The following order was made:—The Board having learned from the workhouse medical officer that a custom prevails in cases of midwifery of sending in the first instance for the medical officer, are of opinion that in cases of this nature the paid midwife should be first called in, and that it rests with her to require the attendance of the medical officer, should the case not present the ordinary features of natural labour.

ABBEYLEIX UNION.

THE APOTHECARYSHIP.

It will be recollected that Dr. Stoney was recently appointed apothecary to the workhouse, which appointment the Local Government Board refused to confirm, on the ground that the dispensing of the medicines was the duty of the medical officer. At last meeting of the Board the following communication was read:—

"Sir,—The Local Government Board for Ireland have had before them a minute of the Board of Guardians of Abbeyleix Union of the 14th inst., in reference to the appointment of Dr. Stoney to compound the medicines for use in the workhouse; and I am to state that under the circumstances the Local Government Board will issue an order authorising the appointment of a second medical officer for the workhouse, and the appointment must be made in the usual way.—By order, &c.,

"B. Banks, Sec."

LIST OF ENTRIES IN THE REGISTER OF THE BRANCH MEDICAL COUNCIL (IRELAND) FOR THE MONTH OF MAY, 1878.

May 3rd.—McComb, Wm. Taylor, 19 Charlemont Place, Dublin, Lic. R. Coll. Phys. Edin. 1878, Lic. R. Coll. Surg. Edin. 1878, Lic. Apoth. Hall Dub. 1878.

3rd.—Carmody, John Power, Athlacca, Kilmallock, co. Limerick, M.D. 1877, and M.Ch. 1877, Q. Univ. Irel.

6th.—MacCullagh, James Acheson, The Abbey, Newry, co. Down, M.B. Univ. Dub. 1878.

6th.—Murray, John James Goodlatte, 3 College Square East, Belfast, Lic. R. Coll. Phys. Ediu. 1878, Lic. R. Coll. Surg. Edin. 1878.

7th.—Furlong, John Joseph, 17 George Street, Limerick, Lic. Apoth. Hall Dub. 1876.

7th.—Wall, Henry Arthur, 28 Lower Baggot Street, Dublin, Lic. R. Coll. Surg. Irel. 1877.

10th.—Linden, Henry Cooke, 29 Laburnum Terrace, Antrim Road, Belfast, Lic. R. Coll. Phys. Edin. 1878, Lic. Fac. Phys. & Surg. Glas. 1878.

10th.—Hueston, James Lyle, Gortade, near Maghera, co. Derry, Lic. Fac. Phys. & Surg. Glas. 1878.

13th.—Fogarty, Thos. Frederick Willoe, 22 Kenilworth Square, Rathgar, co. Dublin, M.B. 1877 and B.Ch. 1878 Univ. Dub., Lic. Mid. 1878 K. Q. Coll. Phys. Irel.

13th.—O'Mullane, Eugene Joseph, 8 Church Gate Street, Bury St. Edmunds, Lic. 1876 and Lic. Mid. 1876 K. Q. Coll. Phys. Irel., Lic. R. Coll. Surg. Edin. 1878.

15th.—Sweeny, Terence Humphreys, 83 Upper Leeson Street, Dublin, Lic. R. Coll. Surg. Irel. 1877, Lic. 1878 and Lic. Mid. 1878 K. Q. Coll. Phys. Irel.

WEEKLY REPORT OF HEALTH OF DUBLIN AND SUBURBS FOR WEEK ENDING MAY 25, 1878.

Total registered deaths in Dublin and suburbs*			... 202
Ten years average of same week	...	...	... 145
Excess of mortality above average	...	...	... 57
10 weeks' ratio of deaths Rathmines		24·3	per 1,000
„ „ „ Donnybrook†		25·3	„
„ „ „ Blackrock		15·2	„
„ „ „ Kingstown		16·9	„
„ „ Entire Dublin District		33·4	„
Comparative Ratios—London	...	20·1	„
„ „ Glasgow	...	22·8	„
„ „ Edinburgh	...	20·8	„

* District extends over 10,050 acres, and contains 314,666 persons.

† This district includes City of Dublin and Incurable Hospitals.

The deaths from zymotic diseases registered during the week number 46, being 11 less than in the week ending 18th inst., but 20 over the average number in the 21st week of the last ten years; they comprise 15 from small-pox, 8 from fever (4 typhus and 4 typhoid), 9 from whooping-cough, 2 each from quinsy and croup, 4 from diarrhœa, 1 each from scarlet fever, measles, dysentery, &c. The deaths from small-pox are 6 less than in the preceding week, but 3 more than in the week ending 11th instant; 6 are chargeable to the North City, and 9 to the South City, 6 of the latter number being deaths of inhabitants of Peter Street district. The number of cases of small-pox under treatment in the Dublin hospitals (including the temporary hospitals in connection with the two union workhouses) on Saturday last was 267, against 270 on the preceding Saturday; 94 cases were admitted during the week, being 12 less than in the previous week; 82 patients were discharged as as cured, and 15 died.

Fourteen deaths (of children) from convulsions were registered during the week.

The mortality from diseases of the respiratory organs continues high. The average number of deaths from these causes in the 21st week of the ten years 1868-77 was only 25, while the number recorded last week is 42, viz., 25 from bronchitis, 12 from pneumonia, 1 from laryngitis, and 4 from lung disease unspecified.

Ten deaths were attributed to heart disease, 1 each to aneurism and pericarditis, 6 to paralysis, 5 to apoplexy, 2 to cephalitis, 4 to brain disease unspecified; 4 to liver disease; and 2 to kidney disease.

Phthisis caused 20 deaths, mesenteric disease 3, scrofula 2, hydrocephalus 3, and cancer 5.

Eight accidental deaths were registered.

PAROTITIS.

In connection with the preceding paragraph, we may mention two interesting cases of parotitis in the *clinique* of M. Empis at the Charité, communicated to the Paris Clinical Society (*France Méd.*) by M. Mercklen. The first followed a uterine affection complicated with peritonitis and an obstinate diarrhœa. It was succeeded by pleurisy. Here, then, we have a condition of health often recognised as likely to give rise to this disease. The second case appeared at the beginning of rheumatic fever in a strong man, and would not at all be anticipated. Indeed, we know of no other recorded case in which this has been seen. There had, indeed, been angina, but this was not believed to be a cause. Still, we think it is often associated with it. An abscess formed near Steno's duct, and possibly this had much to do with it. M. Mercklen asks if it could be rheumatic in its origin, and admits the improbability of such an explanation. No such case is mentioned by M. Iszenard in his thesis, and few will admit any association between parotitis and acute articular rheumatism. In this case pus was discharged freely from three several openings—one by the knife—and the patient did well. No cardiac complication occurred.

Table *showing for* Eight Large Towns, &c., *the* Area, *in Statute Acres; the* Population *in* 1871; *the* Annual Rate of Mortality *per* 1,000 *Inhabitants represented by the Number of Deaths registered during the Week ending Saturday, May* 25, 1878; *the Total Number of* Births and Deaths *registered during the Week, with the Number of* Deaths *at certain Ages, and from* Several Causes, &c.

THE INNER LIFE AND ECONOMY OF A LOCK HOSPITAL IN INDIA. (a)

By Surgeon-Major W. CURRAN,
Army Medical Department.

(*Continued from page* 467.)

Registration of Prostitutes and Area of Supervision.—All the registered prostitutes are, of course, subject to supervision, and the area of this control extends for five miles around cantonments. It includes the Sudder and regimental bazaars, Alum-Nuggar, Thompson-Gunge, Sitapur, and Khyrabad. The public women who elect to reside within the boundaries of cantonments, or who are known to ply their trade chiefly among soldiers, are examined weekly by myself in person, while those from the more distant parts are examined once a fortnight.

This arrangement is, however, subject to be modified by the requirements of the local situation at any moment, at my discretion or under orders to that effect from the local authorities, and, as a matter of fact, I examined them all every seven days for several weeks during the last summer, when there happened to be an unusual prevalence of "venereal" among the troops. In addition to this weekly inspection, any woman with whom an infected soldier may have had connection, or from whom he may consider that he has contracted disease, is, on being identified by him, brought to hospital and inspected by myself or the native doctor. It frequently happens, however, that these women are found free from disease, and this is not to be wondered at when we take into account the state as regards sobriety, darkness, excitement, or *insouciance*, under which soldiers resort to native bazaars. I will only add that villagers or vagrant women from other localities are known to prostitute themselves in groves and other retired places near cantonments whom it is often impossible to identify or arrest owing to the reluctance or inability of the men to assist the police; and that the speculum is rarely required for purposes of examination in this hospital.

The old dhai, who has acquired, from long practice, a peculiar aptitude for exposing the os, inserts the index and second fingers of the right hand into the vagina in front of the anus, while she produces extension of the perineal parts downwards by thrusting the same fingers of the left hand into the passage under the symphysis pubis from above. In this way, as well as by a judicious manipulation of the vaginal walls, she exposes the parts so thoroughly in a few seconds as to render them obvious to any onlooker, and an amount of examination is got through in this way in a few minutes, which several hours with the speculum would scarcely complete. This process was exhibited by me to the local deputy surgeon general I. F. on the occasion of his recent visit to this place, and appeared to meet with his approval. (a) Were it employed at home we would hear less of those scandals which are so much to be deprecated than we now do, unfortunately. Imputations of indelicacy or impropriety would, in fact, be impossible under such an arrangement.

Statistics.—The following table shows the average strength, as well as the percentage of admissions, discharges, deaths, &c., that took place during the past year, and I regret that the data at my command, will not allow me to institute any very reliable comparisons between it and the years that have passed. No fee is charged for registration; any woman not actually under coverture may apply for a ticket to the cantonment magistrate, and this is scarcely ever refused, The ticket costs two annas, and is supposed to last for a year, but it rarely does so,

(a) It may be necessary to explain, for the benefit of those who do not understand Hindoostani, that the word "purka" means, in reference to a well, wall, or building, masonry, as distinguished from clay; while the words "dhai," "chowkedar," and "bhistie," mean respectively a nurse, a watchman, and a water-carrier.

(a) This applies, however, more to the older prostitutes than to the younger ones, in several of whom the speculum can alone be employed with safety. We have been foiled by the narrowness of the outlet in two cases in our endeavours to introduce the instrument available here, and we always resort to its use where the instability or tension of the parts so suggests or requires.

and meanwhile its owner may at any time claim her discharge from the register on giving satisfactory proof of an altered life, or other employment.

TABLE No. 4.—*Being a Return of the Average Strength, etc., of the Registered Prostitutes of Sitapur from 1st January to 31st December, 1877: together with the Averages of the Sickness, Discharges, etc., etc., that took place during the same period.*

Particulars.	Nos.	Remarks.
Average strength of prostitutes	103·45	The number of registered prostitutes has been steadily increasing since prostitution became legalised in this station, and it is greater this year than ever. The ratio of admissions to strength has increased in proportion, and this increase is otherwise accounted for by my desire or endeavour to stamp out or minimise the disease in this small isolated station, and consequent detention of trivial cases. The other items explain themselves.
Average daily sick	13·94	
Number of admissions ..	322	
Number of discharges ..	325	
Number of deaths	Nil.	
Percentage of strength to admissions	0·23	
Percentage of admissions to discharges	0 24	

European Troops and their Liabillty to Disease.—The European Troops stationed in this garrison during the past year were—the head-quarters and right wing of H. M.'s I. 14th regiment and the corresponding portions of H. M.'s 92nd Highlanders. The records of the former are not, I regret to say, now available for reference by me, and, as regards the latter, I submit a table which shews, at a glance, the venereal diseases for which the men of that corps were treated from the 2nd of February —the day on which they reached this station—till the 31st of December last, inclusive. Eliminating from this, as is only proper under the circumstances, the items marked "primary and secondary syphilis, which were obviously not contracted here, we have still a large amount of inefficiency to account for, and yet is this considerably less than was that of its precessors. The admissions to strength in the I 14th amounted in 1876 to 323·68, while they have only reached 240·08 in the 92nd, and while only 93 of the latter suffered from disease contracted in Sitapur, 147 of the former were the victims of a local infection. Gonorrhœa was, unfortunately, the prevailing disease amongst the troops, a good deal of which, there is reason for believing, was contracted from unlicensed women in the vicinity of cantonments or in the outlying jungles, and a medical inspection that was instituted by myself in June last, in the 92nd, brought to light a considerable amount of latent "gleety" disorder in that corps. For the rest, Table No. 5 will explain the situation, and, high though the percentage of admissions be, yet does it compare favourably with the experience of the past, and I am weak or vain enough to hope that, if the rigid standard aimed at by myself will be carried out, the disease may be still further reduced, if, indeed, it cannot be quite minimised in this station.

TABLE No. 5.—*Being a Return of the Admissions for Venereal Disease that took place in H.M.'s 92nd Regiment—the "Gordon Highlanders"—as well as of its Seasonal Variations, from the 2nd February to the 31st December, 1877, inclusive.*

In addition to the above, there was a battery of Royal Artillery in the station, which left it *en route* for England on the 19th of last October. This battery, E 19, R.A., was succeeded on the 10th of December by another, viz., I 5, R.A., and this is the one now on duty here. It brought with it from without five cases of venereal, and, regretting that the absence of records will prevent my giving particulars of the wing of the I 14th regiment, I subjoin tables respecting the others, and leave these to speak for themselves.

TABLE No. 6.—*Being a Return of the Admissions for Venereal Disease that took place among the men of H.M.'s E 5th, late E 19th, Battery, Royal Artillery, from the 1st January to 19th October, 1877, inclusive.*

The following table is more explicit, and it shows very forcibly the risks to which soldiers are exposed on the march in this country. There is reason to believe that many of our rest camps are infested by a low class of prostitutes, who, dreading restraint, or unable to obtain a livelihood in any other way, squats down on the spot, or prowls about in quest of prey, whenever the opportunity offers. (*a*) This, of course, only occurs in the cold weather, when, alone, marching is practicable in India; but the fact—and such it undoubtedly is—tends to show the immunity with which this dangerous calling can be practised out here, and the mischief the system entails is

(*a*) The extent to which prostitution flourishes in this country may be inferred as well from the statistics of venereal diseases among our troops as from the fact, attested lately, in my presence, by no less a person than the general officer commanding the Oudh division, that there are 8,000 prostitutes in Lucknow alone, and Sir William Sloman, who had access to all the State records, &c., under the old *regimé*, states, in his interesting "Journey through the Kingdom of Oudh," that the man who licensed prostitutes in that city in the good old times paid £30,000 a year for that exclusive privilege.

simply incalculable. A regiment of no unusual strength lately passed through this station which bore 43 venereal cases on its hospital-rolls, which were, I believe, mainly contracted on its march, and the subjoined table speaks for itself in the same direction.

TABLE No. 7.—*Being a Statement of the Prevalence of various forms of Venereal Disease among the men of H.M.'s I 5 Battery, Royal Artillery, from 10th to 31st December, 1877, inclusive.*

An Epitome of the Three Annual Statements required by Government.—Of this statement, which is taken from the three annual statements that are required by the local Government, and which is condensed to the utmost to save time and space, little need be said, inasmuch as it carries its own interpretation along with it, and the items of which it consists have only a local or technical interest. It is intended to exhibit, in as short a compass as is possible, the constitution, working, and general management and expenditure of a lock hospital in this country, and the particulars it embraces in respect of each of these are believed to be so far exhaustive.

General Summary and Conclusion.—As far as can now be ascertained, there was no such change in the character or amount of the venereal disease that obtained in this garrison during the past year as calls for, or would justify a special record, and it may be assumed that there is a good deal of correspondence or agreement between the complaints that are found amongst the licensed women and those that are treated in our local military hospitals. This is not, however, always the case, and the absence of it induced me to institute an inspection of my charge in June last, which disclosed a good deal of latent disorder in the same, and led to a correspondence on the subjects of illicit prostitution and police supervision. It also not unfrequently happens that women who are accused by soldiers of infecting them are found to be healthy, and the occasional supervention of a gonorrhœa on an old-standing gleet, or its recurrence after a bout of drink, unusual effort, &c., goes far to prove that it—gonorrhœa—is often as much the result of a mechanical or of a catarrhal irritation of the urethra as it is of an impure connection, or of a specific poison. However that may be—and this is clearly not the place for a technical discussion of the point—I prefer acting on the latter supposition, and accused women are accordingly ordered to be kept in for my personal inspection. If found diseased they are, of course, subjected to treatment on the spot, and I am enabled to judge of the manner in which my instructions are subsequently carried out by the results achieved in my absence by the native doctor and the dhaï on duty.

TABLE No. 8—*which is an Epitome of the Three Annual Statements required by Government—is intended to show the Class of the Hospital, and specify the Authority under which it is conducted. It also shows the Changes that take place in the Personnel of the Prostitutes themselves, as well as their liability to Disease; and the Items subjoined, respecting Expenditure, will easily admit of being compared with those of different, or similarly-constituted, Institutions elsewhere.*

Month.	Average No. of prostitutes on the register for each month, and for the year.	Average No. attending the periodical examinations.	No. reported for non-attendance. Having now, for the second time, under treatment for gonorrhœa and mucous papules a deaf-mute girl of a low type of mental organisation, who is said to prostitute her person under trees, &c., for a few pice, to all comers, and having also under my care another idiotic or epileptic woman, who is in a fearful state of filth and destitution, I think it my duty to call special attention to this class of cases, and to impress upon the Civil authorities the propriety—nay, the necessity—of removing these poor creatures to some place of shelter or of refuge, wherein they may be protected against themselves, and prevented from practising a calling for which they are so obviously unsuited. These wretched women can scarcely be said to be responsible for their actions; they must either sin or starve, and they are sowing infectious disease broadcast, almost, it may be said, through no fault of their own. Their very helplessnes or incurable maladies ought, of themselves, to establish a claim for them, in a country like this, on the consideration of Government, and their want of cleanliness, as well as their promiscuous mode of indulgence, are peculiarly favourable to the development of the diseases here contemplated. It is not too much to say that they have been already the cause of a good deal of mischief of this kind in this very garrison, and I am of opinion that one woman of this class is more dangerous in herself alone than a dozen of her cleaner or more discriminating sisters.

The British soldier is, as we all know, not very particular in the distribution of his amorous patronage. He selects his partners without fear or favour, in the darkness of the night, as well as under the shadow of a tree, or within the shelter of a cornfield or a nullah. He likes variety, but dislikes paying much for it, and there is reason to believe that he is not altogether averse to the kind of pariah-gratification afforded by these women. Anyhow, there is evidence to show that they are unable to compete on equal terms with their sisters; they have to go elsewhere—to the jungle or the common. They are frequently—much more so than their neighbours—diseased, and I am of opinion that such women should be no longer allowed to roam at large as they do at present in this or any other military cantonment.

There can be no reasonable doubt that, as noticed by one of my predecessors, "the women convicted of unlicensed prostitution sent up for examination were generally found to be suffering from a more virulent form of disease than those who were more regular attendants," and the reasons for this are so obvious as to dispense me from the necessity of doing more in this place than dwelling on the claims of the latter to protection, and insisting on the necessity of improving or extending the detective system now in force. I am aware that rewards are supposed to be given to these men when they succeed in catching an unlicensed woman with an European soldier, but they are, I fear, too small, if, indeed, they are ever disbursed at all, to counteract the other influences that are, or can be, brought to bear on these officials, and, taking into account the odium that must necessarily attach to such a duty. I would strongly recommend the institution of a regularly-graduated tariff of fees for these services. The dhaïs, and even the registered prostitutes themselves, might be included in the same list—the former on account of their greater local knowledge; the latter through their pockets. Their natural dislike of "poachers" would stimulate their scent, their instinctive sense of self-preservation or love of emolument would concur, and any woman who succeeded in convicting a noted trespasser might be either rewarded on the spot or have remitted to her any fines she may incur within the current year. Whether this suggestion can be carried out or not, I am unable to say; I feel, however, that it deserves consideration, and I feel, further, that were some combined measure of supervision, such as I have ventured to suggest, efficiently carried out, we might, in time, minimise, if we did not actually succeed in entirely stamping out venereal in this station.

One more suggestion and I have done. When I first thought of writing this report I looked about me in vain for any guide as to the form it should assume, or as to the points on which I should dwell in connection with it. I was not even made aware of the necessity of such a report at all until the local Deputy Surgeon-General, I. F., Dr. Hutchinson, told me so on the occasion of his recent visit here, and the scattered memoranda to which I had access are quite insufficient for such a review as the general surroundings and situation deserve. This will account in some measure, though not, of course, altogether, for the diffuseness or incompleteness of this statement. I did not know how to begin or where to stop, and I must plead the above in extenuation of my shortcomings. To obviate a similar failure in the future I would suggest that a printed copy of this—should it happily achieve that distinction—and such other preceding reports as are now available should be filed for future reference in our lock-hospital office here. The orders of Government that bear on the subject might also be included, and medical officers are now so liable to change that no one man can be sure of being left in charge of this or of any other local institution of the kind for even a year.

Facts of medical or military interest are constantly accumulating in connection with these establishments which it is desirable to preserve and collate, and this can only be done after the fashion here recommended. The very nature and origin of syphilis are, notwithstanding all that has been written about them, still moot questions, and it should not be forgotten that these women are themselves incapable of affording any reliable information on these points. They are above reproach, or so callous to shame as to be indifferent to the consequence of their conduct, and the restraint to which they are subjected affords facilities for clinical study and observation which have no parallel elsewhere in *our* dominions.

For these and other reasons too numerous or too technical for mention here, I venture to suggest, as above, that copies of this and other documents of like import should be deposited in our office here; and I will only further add, that any or such women as manifest any other than a venereal complication or disease during their attendance or under inspection, are sent, as soon as their more special requirements will permit, for further treatment, to the Civil dispensary.

(To be continued.)

THE REMOVAL OF FOREIGN BODIES FROM THE EAR.

By ROBERT T. COOPER, M.D. Dub.

THE many recent communications upon this subject in the journals show how much interest is being taken on the subject of aural therapeutics; the lesson we learn from one and all of them is, it seems to me, the important one summarised by Hinton ("Aural Surgery," p. 73), when he says, "that whenever an instrument will succeed (in removing a foreign body from the meatus) syringing would also succeed, and that when proper syringing will not succeed all instruments are *full of danger.*"

This being the case, it is very necessary, if improvement is to be effected, that it be done in relation to our methods of performing the operation of syringing.

Now, practically, there are two very different kinds of foreign bodies to be met with in the external auditory meatus; these are, in the first place, *cerumen*, which is to all intents and purposes, a foreign body; and, in the second place, substances such as beads, buttons, and the stones of fruit, &c., that are introduced from without.

In the case of both varieties, it must be admitted to be of extreme importance the being able to *see* the body upon which we are directing the current of water from the syringe. With the ordinary ear specula, as met with at the instrument-makers, this would be impracticable. I

have, therefore, constructed an ear speculum, a description of which appeared in the April (1877) number of the *Dublin Journal of Medical Science*, so constituted by the addition of a spout-handle through which the outgoing current of water can pass, as to enable us to see at each stage of the operation in what way the foreign body is influenced, and upon what part of it we are directing the principal force.

The case of cerumen, however, differs from that of an ordinary foreign body in this most important particular, that force from *in front* is necessary to be expended in order to detach it from the sides of the meatus, and that in order to accomplish this, the force obtained by means of the jet of water playing upon it, has often to be considerable; while, on the contrary, in the case of the true foreign body, no *vis à fronte* is required, and may even be highly dangerous by driving it, perhaps irritating the surface, against the tympanal membrane. In this respect, cerumen stands in marked contrast with the ordinary foreign body, the one offering little or no danger to the application of force by means of an ordinary syringe-stream, and even requiring its application, the other circumstanced so as neither to require nor yet to be free from danger if a forcible syringe-stream be directed upon it. For here comes the distinction between the two: the cerumen invariably occupies the entire channel of the meatus, it is firmly attached to the sides of the meatus, and its tympanal extremity is smooth; the foreign body, contrariwise, scarcely ever occupies, except, indeed, the meatus be very much swollen, the entire calibre of the canal, its sides do not adhere to the wall of the meatus, and its inner or tympanal extremity is often rough and irritating.

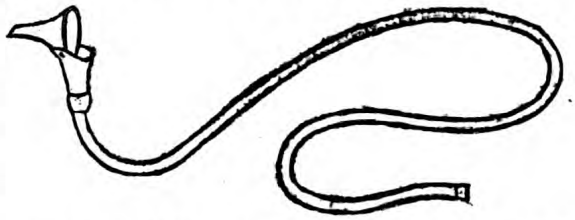
This being the case, while we are justified in playing the syringe-stream with force upon the cerumous body and from in front, we should not be justified in so doing in regard to the true foreign body. Then, let us remember, the foreign bodies that find their way into the auditory meatus are those that introduce themselves there, as is the case with insects, the cockroach, the earwig, &c., or have been forcibly pushed in by the patients themselves, as in the case of children and lunatics.

A moment's thought will convince us that it must necessarily be a very exceptional instance where the foreign body so occupies the entire meatus as not to leave some space between itself and any portion of the wall of the meatus, for the shape of the auditory canal is such that, except midway between the external opening and the drum-head, it is more oval than round, and even in this part of it is subject to much individual variation. And, besides, the cartilage of the ear is so formed as to be deficient above corresponding to the roof of the meatus; "the whole cartilage (Quain's "Anatomy," art. "The Ear," p. 628) may be looked upon as an elongated plate, the lower part of which is folded round in front so as to bring it *nearly* into contact with the upper part." There will, therefore, be a certain amount of deficiency, and hence, we obtain a corresponding amount of space, even supposing the shape of the foreign body to be round, and the question will be how to utilise this space with the greatest advantage.

Now, in removing a foreign body, whether actually impacted or not, our object should be either first or last to drive it *in towards the drum-head*, but to at once direct our force upon it in such a way as to secure the most speedy exit possible for it from the canal.

This, it is admitted by all authorities, is fairly accomplished by our ordinary methods of syringing. But the reason why syringing is so successful an operation is, because sufficient deficiency exists between the canal-walls and the body to be removed to allow of the water getting behind the body before it becomes detached from the sides of the meatus, and in this way protecting the drum-head from injury. But it is evident that the force playing upon the body from in front may, before the water gets behind it, drive the foreign body right against the drum-head, and so cause serious injury.

The rational way, therefore, of utilising any vacant space between the foreign body and the canal-wall will be to insert the nozzle of a syringe constructed so as to terminate by a very fine extremity and to possess a correspondingly minute bore. The object of this will be to enable us so to utilise the space as to syringe in such a way as will cause the water to accumulate *behind* the foreign body and *between it and the drum-head*, and swelling up from behind will, therefore, take place, and as the water accumulates pressure will be brought to bear upon the body from within, the tendency of which will obviously be to drive it outwards. But in order to perform this delicate operation satisfactorily it is necessary that we should have in clear view the body we are seeking to remove at each step of the operation, and this advantage we can obtain only by the employment of my spout-speculum as pourtrayed in the adjoining woodcut.



This nozzle of the syringe is so constructed that while the nozzle itself is as free as possible, so as to occupy very little space, its extreme end slightly bent so as to fit *over* the foreign body, and, at the same time, steady it, and it is bored in such a way as to leave the tube of it to find an exit above and somewhat short of the tip. In this way the pipe of the syringe effects the twofold object of steadying the foreign body and shutting off any of the forward force of the syringe-stream abutting upon the foreign body.

The same object might be gained, but perhaps not quite so effectually, by having a loop of silver-wire, made like the end of an ear-scoop, attached to the syringe-pipe; this would steady, and, at the same time, if needed, press down the foreign body, while space would, in this way, be gained for the entrance into the meatus of the syringe-stream.

The spout-speculum and a specially-constructed syringe, are to be had of Messrs. Arnold & Sons, Instrument Makers, Smithfield.

6 Ladbroke Road, Notting Hill, W.

ABSORPTION OF TUMOURS.

By CHARLES W. HAMILTON, L.R.C.P. Ed.

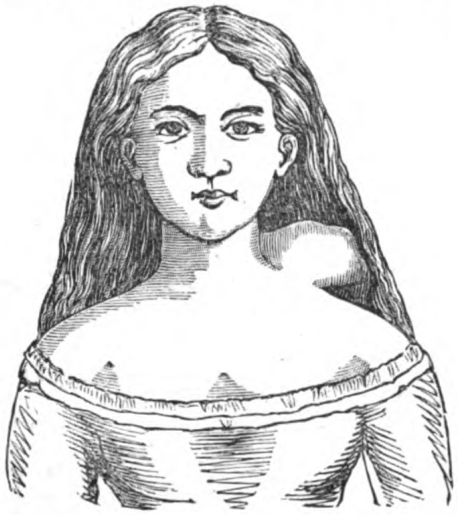
Licentiate of the Royal College of Surgeons in Ireland;
Medical Officer of Achill;
Admiralty Surgeon to Sick Marter's, Achill, Ireland, &c.

Miss H., a young lady, consulted me some time since about a large tumour, situated in the posterior inferior triangle of the neck. Its large size and exposed situation caused considerable deformity to this otherwise good-looking young person. It measured 3 inches from base to apex; circumference, about fifteen inches. The woodcuts are faithful representations, both before and after being cured, and are taken from sketches drawn by a professional artist from life. The tumour felt hard, and seemed encapsuled; the patient presented no symptoms of a scrofulous tendency. She desired me to remove it in some way, and if all failed, promised to submit to the knife. I prescribed the following:—

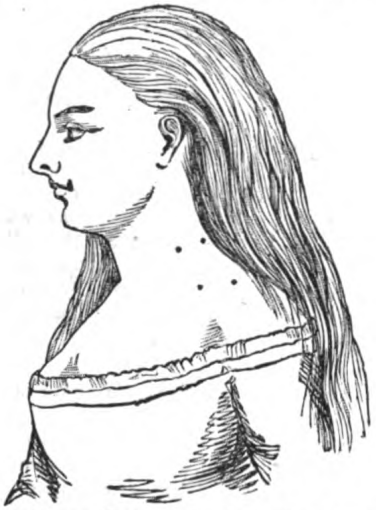
℞ Potass. iodid., ℥j;
Tinct. iodi., ℥j;
Syrup. aurant., ℥ss;
Aqua, ad ℥s. ℳ

Of this mixture I directed her to take one tablespoonful three times a day, also one Plummer's pill every second

night. She faithfully obeyed those directions for three weeks, without the slightest effect, one way or other, to the enlargement. Being a nervous, hysterical young person, was averse to operating until I should have fully tried out absorbent remedies. I contented myself with passing two silk threads midway through the tumour. I applied the ung. iodi. over the entire of it. On the second



day, I withdrew one of the threads, and again had the ointment rubbed over the situation. I now carefully watched for the slightest indication of a rigor (being afraid that this treatment might lead to an unsightly cicatrix, for which I knew I should not be thanked), on which I withdrew the seton; inflammatory action had commenced where the threads had been. I substituted the ung. potass. iod. now for the stronger preparation, and had it applied to the entire tumour morning and night; she had been using the mixture from *the first application of the setons*. This treatment had been continued for three weeks more. After the withdrawal of the threads, some serum,



slightly coloured, oozed through the minute perforations, which soon became quite *transparent*, as the more active remedies *were discontinued*. At the end of the third week of this treatment, and sixth from the commencement of first coming under observation, a visible diminution took place, and by the end of the fourth week *the tumour had entirely disappeared;* the only traces where this enlargement had been were four minute depressions, like pinholes, which could not be detected *unless looked for*. As she told me herself, *she could now wear a low dress*.

Remarks.—Many remarks might be appended to this interesting case, but I will content myself with noticing only some points in the treatment, viz.—(*a*) I believe the iodide of potash *had no effect* on this tumour (it had likely on the entire body) until its action had been *directed, so* to speak, by the setons, &c. (*b*) Had the seton been left in longer, *suppuration would have set in, and spoiled the cure*, causing, as I remarked before, a very unsightly cicatrix. The nicest point in the treatment being to *bring on suppuration*, and then *check it*, this is nicely shown in the *coloured serum again regaining its transparency*. The weaker ointment (ung. iod. pot.) to be substituted for the stronger (ung. iodi.), for the above reasons. (*c*) A most important part of the treatment, in my opinion, is to continue the internal administration of the iodine up to, and even after, all trace of the tumour has vanished. (*d*) Some slight coryza troubled this patient from the continued use of the mixture, but stopping one day always cured it. (*e*) I believe this tumour to have been adenoid, but think this treatment might be used with other varieties in similar situations. (*f*) Removing this tumour by a single operation would have been tedious from its situation, and, with a history of scrofula, not inviting, and without doubt a more unsightly mark would have been left.

The tumour had been growing for two years, and during the last half year, had remained *in statu quô*. I may add that this young lady had been under treatment for this affection before coming under my care, but without any benefit.

Clinical Records.

SHORT NOTES OF A BALL PESSARY RETAINED IN VAGINA FOR THREE YEARS AND A-HALF.

By Dr. G. de Gorrequer Griffith,
Senior Physician to the Hospital for Women and Children; Consulting Physician-Accoucheur to St. Saviour's Maternity.

Sarah Fitzwater, æt. 37, married, had four children, and been a widow for seven years. All her labours had been very hard, the first being accomplished with instruments; the last also hard, though terminating quickly at the close, and being ended before the doctor came to render any assistance. Immediately after getting about she felt the womb fall, and come lower and lower down, till at length it seemed all but out; she was obliged to apply to a hospital, where the instrument was inserted, she, to use her own words, being told at the time that it would not come out unless taken away by operation. It is about 3½ years since the pessary was inserted; immediately after its placement in the vagina she noticed the bowels became confined, not being moved for three or four days at a time, though before this they had been rather regular; the pains, when a motion had to be passed, were like those of labour, and during them the ball would be forced to the os vagina, where it would be stopped by the action of the sphincters (as I ascertained before I extracted it), the rectum being tightly closed, the vagina also being so tightly constricted that the finger could only be introduced with difficulty when the instrument was pushed up towards the os uteri, and thus out of the way, the bowels could be evacuated, and this was the necessary mode of procedure before each movement.

On November 23rd the patient presented herself to me at the Hospital for Women and Children, stating that she was in general bad health, and could not make out the cause of it, unless it was from overwork. On questioning her I ascertained the history I have narrated. On Nov. 24th she came to me again; there was an intensely fœtid, blackish-brown discharge from the vagina, and, on introducing Fergusson's large-sized speculum, the vagina was found exquisitely tender, eroded, and granular, in its entire surface, and at the apicial opening of the speculum was seen a blueish-black or purple mass, looking very like a blood-engorged tumour extruding from the os uteri, or like the fœtal surface of the placenta, presenting itself

as a blue shining mass through the os uteri, and being there packed tightly and compressed. The discharge was excessively offensive, and she could not even bear the finger to be moved in the vagina. I therefore asked my colleague, Dr. Folwell, to give her chloroform, and, with his aid and that of my assistant, Mr. Bamber, I extracted this large spherical wooden pessary, by means of one blade of the short forceps and the first two fingers of the left hand, having first lubricated the vagina as well as I could by means of oil syringed into it. Afterwards the passage was well washed out and cleansed by means of Condy and warm water, the syringe being used for the purpose. All the constitutional symptoms quickly disappeared, and she became healthy-looking and ruddy, showing that the state of toxæmia existing before I removed the pessary was due to the offensive discharges created, and, in a measure, pent up in the vagina, these symptoms being aggravated by the constant irritation of the offending pessary.

9 Lupus Street, London, S.W.

Special Correspondence.

[FROM OUR SPECIAL CORRESPONDENT.]

Paris, Rue de Luxembourg,
June 5, 1878.

It would be a French compliment were I to ask your readers to come to Paris, for some might take it as a personal invitation, and my friends are too numerous, and at the same time my house too small to accommodate all whom I should like to see here, so that I can only advise or prescribe that all jaded, overworked practitioners seeking a holiday should seriously think of visiting La Belle France.

Pleasure may be combined with science. Enlarged views of humanity will be acquired, insular prejudices toned down, fresh ideas developed, new inventions for surgery studied by a visit to the Exhibition. In the midst of the myriad treasures of art and of luxury, of apparatus and machinery of every conceivable kind, and of the thousands who are arriving to inspect them, one feels what a cypher one is in the scheme of creation.

Some of us require such a corrective for the "ego," for the eradication of old ideas, not only about "British interests" but British surgery, and they will there find that surgical or medical skill is not confined to our favoured race, but that the Paris hospitals open out a wide field for thought, study, and research.

The courtesy of our French *confrères* is not only proverbial but founded on fact. The visitor will have little difficulty in obtaining introductions to some of the principal hospitals, as the Necker, Hôtel Dieu, Salpétrière, &c., and of attending some of the demonstrations of the *chefs* of the Paris School of Medicine.

Even in the Exhibition there is evidence of the forethought and *desire* of the profession in Paris to provide for the comfort of their foreign visitors, for a suite of rooms are prepared where foreign visitors may obtain all necessary information regarding the *cliniques* of the various professors, the hours of attendance at hospital, operations, special lectures, and where all inquiries will be courteously and promptly answered.

There is a special medical staff appointed for the Exhibition in case of temporary illness, with ambulance, &c., under the supervision of Dr. Ladriet de Lecharrière, and a staff composed of MM. Audige, Testaud, Venet, Benoit, Grenet, Kuhff, Le Coin, and Sottas.

In connection with the medical department, there is also a room for lectures, so that even within the building science may be studied.

Thus, names known only by reputation may become living realities, and the practitioner interested in French medicine or surgery may see or hear the leaders of the Paris profession, as Charcot, Pasteur, Germain, Sée, Guyon, Desprès, Hardy, Broca, Bouchard, Tillaux, Vidal, Bouchut, Terrillion, Le Fort, Chauffiard, Peter, Bell, &c. Should the visitor desire to leave the atmosphere of professional life, and give himself up thoroughly to enjoyment, he will find amusements in endless variety, in the Exhibition, in concerts, theatres, cafés chantants, in the parks, museums, picture galleries, &c. Pleasure invites on all sides. There is only one drawback—money will be wanted. During this period hotel proprietors are asking fabulous sums for maintenance; in fact, a golden harvest is expected to be reaped out of the pockets of those who honour us.

What does it signify? Life is short, and, though our art is long, we must, in return, extract some of the golden salve, if not from the pockets of our patients, from the balance at our bankers', and scatter it for the good of humanity in general and of the Paris bourgeoisie in particular. For those who have no balance at their bankers' my advice would be—"Go to Bath." (*Mem.*—Meeting of British Medical Association, August 6th, 7th, 8th, and 9th).

The pleasure side I must leave; each visitor will, I am quite certain, be able to select for himself the form of amusement suited to his own individual taste, whilst I confine myself to some subjects of professional interest.

One of the most brilliant reunions of the French Association of medical practitioners has just been held; its 20th session under the presidency of M. Henri Roger.

It is not analogous to your British Medical Association, for though it brings together, and cements the bonds of union between, the vast body of physicians and surgeons throughout France, it has the more special object of relieving the wants of indigent members, who after a life of labour, ungratefully rewarded, and devotion to the cause of humanity, through unmerited and accidental causes have to appeal to the charity of their *confrères*.

We seem to be a poor profession, universally poor, not only because we are forgetful of our own interests, but because an unappreciative public, whilst it accepts our services, does not pay us adequately, or does not pay us at all; receiving eleemosynary aid at hospitals, dispensaries, which too often is abused by persons who are capable of paying. Hence the necessity of helping our poorer brethren.

We are a charitable profession beyond doubt, and this meeting proved the widespread interest in the movement by the numerous delegates sent from local societies, by the subscriptions, and by the applause which greeted the report of M. Bucquoy, announcing that all the claims for assistance had been granted. I may here mention, as I am speaking about societies, the French Association for the Advancement of Science will open on 16th or 22nd August.

President.—M. Frémy.
Vice-President.—M. Bardoux, Minister of Public Instruction.
Sec.-General.—M. le Commandant Perrier.
Vice Sec.-General.—M. Le Comte de Saporta.

In order to contribute to its greater success, the Municipal Council of Paris have arranged that some of its members should co-operate with the delegates of the Association, and MM. Bourneville, Cadet, Caubet, Combes, &c., have been appointed as members of a commission for that purpose. Thus there may be a great scientific and intellectual treat *in posse*.

It will be interesting to sanitary reformers and medical officers of health to know that an international congress of hygiene will meet at the Palace of the Trocadero from the 1st to the 10th of August. A programme of the questions said to be discussed has already been issued. As the agency of the Congress is installed at the Tuileries, and as the office is open from 1 to 5, hygienists can readily obtain copies of the programme of the Association.

At present it is difficult to select from the various

excellent lectures or courses in progress of delivery one for special notice.

As syphilis is at all times an interesting theme, and an almost universal disease, entailing results of the most disastrous nature, I may briefly refer to the course of lectures commenced by M. Cornil on the 21st May at the Lourcine, on "The General Pathology of Syphilis," to be continued every Tuesday.

Syphilis he defines to be a virulent malady having a considerable degree of resemblance to glanders and tuberculosis. After a glance at the theories of the unicists and dualists, he insists on the anatomo-pathological differences between soft and hard chancre, the period of incubation being the distinguishing feature. Soft chancre appears immediately after contamination, indurated after a time varying from ten to twenty-five days, and sometimes extending to a longer period, as has been proved by the observations of Langlebert, Rollet, Diday, &c., and the experiments of Wallace, Vidal de Cassis, Waller, and Pellizari. But what takes places between the time of incubation and the appearance of the chancre? Some authors affirm that the individual is contaminated during the period of incubation, the chancre being the local and first manifestation of a general disorder, dating from the day of incubation. Others have denied this theory.

M. Cornil, after referring to the experiences of MM. Riaes, Ricord, Ausfritz, and Unna, considers the most probable hypothesis to be that syphilis is not generalised at the onset, but that the chancre is the first complication which by little and little infects the whole economy.

In reference to other lectures, I may mention that M. Luys is giving a course on mental pathology at the Salpétrière, M. Fournier on affections of the skin and syphilis at St. Louis, and at the Hospitals for Children, MM. Parrot and Archambault on the diseases of children.

Surgeons can study the practice of M. Verneuil at La Pitié, of Prof. Gosselin at La Charité, of M. Broca at the Necker, of M. Richet at the Hôtel-Dieu, of M. Desprès at the Hôpital Cochin; whilst the method lately submitted to the notice of the profession in London, viz., that of dressing wounds with cotton wool, may be seen practically carried out in the *service* of M. A. Guérin. I intended to have sent you the transactions of some of the societies, but must defer them for a future occasion, as also a description of the sanitary appliances and surgical instruments on view in the Exhibition. At the present time relief for the sick and wounded must be a subject of interest in English professional circles. You have, fortunately, not had such practical experience of the miseries of war as the French, Germans, or even Americans, though you have nobly and charitably furnished ambulance and surgeons for the East. I shall devote particular attention to the best and newest contrivances for service in the field, as ambulances, field transport, stretchers, field cases, and medicine chests, splints, &c., and at the same time I shall give a *résumé* of the French Army Medical Organisation, so as to afford a standard of comparison with your system. The English Army Medical Service does not seem popular, the method of recruiting it might be advantageously remodelled, and the experience of other nations should not be lost in the reconstruction of a department upon which the comfort and even the destiny of whole armies may depend.

SANITARY INSTITUTE OF GREAT BRITAIN.

THE first annual meeting of this Institute took place last week in the theatre of the Institute of Civil Engineers, Westminster. Dr. G. B. Richardson, the first President of the Council, occupied the chair. The report of the Council, which was submitted to the meeting, contained the announcement that the institute was free from debt; but it was stated that much of the work they desired to see more efficiently carried on was impeded owing to want of funds.

Dr. RICHARDSON, in moving the adoption of the report, said the Sanitary Institute of Great Britain was not as yet a legally constituted body with a charter, but it had nevertheless appointed a competent board of examiners, and he doubted whether a more stringent examination had been carried out by any of the chartered institutions during the past year. That strictness, however, instead of doing harm, had done good, since it had led to a better class of men coming forward for the offices of surveyors and inspectors of nuisances. When the institution obtained its charter of incorporation it would be the first body established in the kingdom for teaching sanitary matters scientifically and effectually.

The report was adopted, and at the unanimous request of the meeting Dr. Richardson consented to serve for the ensuing year as Chairman of the Council.

Mr. WILLIAM DONALDSON, M.A., C.E., then read a paper on the

PRESENT AND FUTURE WORK OF ENGINEERS IN REFERENCE TO PUBLIC HEALTH.

The share of the civil engineer in the promotion of health comprised the provision of an abundant supply of pure water; the provision of means of removing all polluted matters and the means of their disposal; comprising means of preventing floods, and the drainage of miasmatic swamps, and the provision of an abundant supply of pure air to overcrowded districts. He was of opinion that engineers could bring sewage undertakings into the same category as gas and water supply, and could now prove that if properly and efficiently carried out the annual value of the sewage as a manure, added to the saving of the annual charge for removing night soil and cesspool matters, will pay directly a fair interest on the outlay. In regard to the utilisation of sewage, he said the matter was narrowed down considerably. It being proved that land irrigation was the most effectual means of purification, the principle of intermittent downward filtration over a large area, not over what was considered the minimum for purifying the given amount of sewage to be disposed of. He showed by the experience of Colonel Jones at Havod-y-wen Farm that sewage was most valuable, and that by adopting the system of separating storm-water from the sewage its disposal was a matter of ease within the reach of private enterprise.

THE DINNER.

After the meeting the members of the Institute dined at the Grosvenor Restaurant, Dr. Richardson presiding.

After dinner, the patriotic toasts having been honoured,

Dr. CHADWICK proposed "Success to the Sanitary Institute," coupled with the health of the Chairman, who had most powerfully influenced the progress of sanitation in this country. It was now, he said, high time that there should be undivided and concentrated attention to the promotion of sanitary science in its application to the health of the population. He much regretted that he had not an earlier knowledge of the Chairman's capacity, of his power of analysis and exposition, as well as of his power of invention, that he might have enlisted his services when he was in office, for in that case sanitation would now have occupied a very different position.

Dr. RICHARDSON said nothing could give him greater pleasure than to be present to hear one so esteemed and venerated as Dr. Chadwick speak as he had spoken. He thought the Sanitary Institution had a certain success before it, and that in the history of the future it would take a marked position. For the first time in the history of sanitary science a special institute had been established. There had been an Italian who lived more than 150 years ago, named Rammazzini, who, if he had existed in our time, would have ranked as the first of sanitarians. This man had studied profoundly many of the questions, such as ventilation, water supply, cleanliness, food, drink, and the effects of trades and occupations, which were now recognised as constituting the foundation of sanitary science, and it had been the dream of his brief poetic life to establish before he died an association of scholars to carry out his sanitary ideas. He had died, however, without his dream ever being realised. In France, again, at the beginning of the present century, a distinguished scholar had endeavoured to carry out a similar project, but with no better success. He believed that their beginning, though in a small way, was the commencement of a great movement, which would lead to the formation of institutions equivalent to our colleges and academies, and other great foundations, and nothing delighted him more than the honour of sharing in its inception and inauguration.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, JUNE 12, 1878.

THE CONSTITUTION OF MALT LIQUORS.

How often do we find people saying that they cannot get on without their beer. How often, on the other hand, do patients tell us that they cannot touch a drop of beer without it disagreeing with them. Indeed, there could not be a better illustration of the truth of the old adage that "what is one man's food is another man's poison" than the experience of different people with regard to the use of this homely and time-honoured beverage. In the *Chemical News* of May 3rd there is an able and suggestive paper on the Constitution of Malt Liquors and their Influence upon Digestion and Nutrition, by Mr. J. J. Coleman, F.I.C., F.C.S. Considering the vast consumption of these liquors in this country, the importance of the subject in a social point of view, and the outcry that has been lately raised against the use of any kind of alcoholic beverage whatever, we shall make no apology for calling the particular attention of the reader to a question in which, as a medical man, he cannot fail to be interested.

A liquid, resembling in appearance British porter, and labelled "Hoff's Malt Extract," has been recently very much in vogue. It has been largely patronised by the medical profession, under the impression that it was a very nourishing and strengthening beverage, and was of great service in restoring the energies of patients suffering from faulty nutrition. Mr. Coleman having in his own person experienced the good effects of this extract in the usual dose of a wineglassful twice or three times a day, has been induced to investigate its composition and the circumstance to which its value as a wholesome and nutritious liquor should be attributed. The mean result of a number of analyses showed it to consist of—

Alcohol	4·00	per cent.
Extractive matter ...	8·12	,,
Water	87·88	,,
	100·00	

The preparation is therefore a variety of porter or beer, and closely resembles in its composition the celebrated Bavarian Bock beer, which contains the same amount of alcohol, but rather less (7·20) extract than Hoff's liquor. The Bavarian beer was much praised by Liebig, who ascribed its "precious quality" to a peculiar process employed for fermenting the wort—that is, fermentation from below. It may also be remarked that Hoff's liquid is something more than "malt extract," as it contains alcohol, and the usual quantity of carbonic acid gas which causes any ordinary fermented liquor to froth up when liberated from the bottles containing it. "But," says Mr. Coleman, "this liquid of Hoff's produces, on evaporation to dryness, an extract which differs from the solid extract usually obtained from British beers. Malt extract obtained from such sources contains a large percentage of crystallisable sugar, whilst that from Hoff's liquid is almost entirely constituted of the dark-brown uncrystallisable extractive matter present, but in less proportion, in the beers of this country."

The most interesting question for consideration is: To what constituents of Hoff's liquid are to be attributed its marked physiological effects? Relying upon the evidence of Drs. Edward Smith and Richardson with respect to the action of alcohol on the system, Mr. Coleman rejects the idea that the spirit in the "malt extract" has anything to do with its dietetic virtues. And even on the assumption that alcohol is a food, he considers that the quantity of carbon contained in the alcohol present in Hoff's liquid is so small (not more than 150 grains) in proportion to the quantity (from 4,000 to 6,000 grains) consumed daily by an average man that it could add very little to the nutrition of the body. But Mr. Coleman very justly observes, although these liquids have no food value of any importance, may they not have the power of influencing the digestion of other food? If the extractive matter of beer and porter be really malt extract—that is, if it possesses the qualities of original malt—then the question is answered affirmatively. It is well known that if lukewarm water be poured upon fresh bruised malt a certain principle dissolves, which, from the difficulty of separating it in the pure state, has hitherto evaded chemical analysis. This substance, called diastase, is a ferment, being capable of converting an indefinite quantity of insoluble starch, through the stages of soluble starch and dextrin into the final product, glucose or grape sugar.

For reasons we cannot here mention, malt liquors may contain little or no diastase; but the nature of these ferments is very obscure, and it occurred to Mr. Coleman that the extractive matter of our ordinary malt liquors might contain the elements of a ferment in some latent form ready to be called into activity during the process of digestion. Now it is obvious if malt liquors exert a solvent action upon starch (a substance which constitutes 47·4 per cent. of wheaten bread), the phenomena can be

investigated externally to the stomach, provided the necessary precautions be taken. Consequently, Mr. Coleman instituted several series of experiments to test the solvent action of Hoff's liquid and ordinary beers upon substances containing starch. For the details of these experiments we must refer the reader to the original paper; suffice it to say, that experimental proof was obtained that 4·82 grms. of bread, or about 20 per cent. of its constituent starch, could be dissolved by the agency of Hoff's liquid. It was also found that ordinary beer possesses a solvent power similar to that of Hoff's liquid, but to an inferior degree. Thus Burton ale, Wrexham ale, London porter, and Hoff's liquid dissolved 15, 26, 40, and 60 per cent. of starch respectively. Thus it was not the richest ales coming from our large breweries which afforded the best result; which may be explained in two ways—either from the fact that in large breweries the diastase of malt is made to go as far as possible, by using raw grain with the original malt, or, secondly, as suggested by Dr. Wallace, from the excess of alcohol in strong ales precipitating the diastase before it reaches the consumer.

In an eighth series of experiments all sources of error existing from the action of the malt liquors upon the gluten of the bread were removed by using pure starch, and the result was as satisfactory as those obtained from previous experiments. Chemically it is interesting to know into what substance or substances the starch is transformed; whether into ordinary dextrin, Bechamp's soluble starch, Dubunfrants' maltose or ordinary glucose; but at all events, Mr. Coleman's experiments appear to have established a food value for malt liquors not before known, and if the results of his investigations are confirmed by other chemists and physiologists, the poor man's beer will not be so much at a discount as it has been lately, while the known action and properties of malt liquors will enable the practical physician to judge in what cases they may be beneficially prescribed.

We cannot, however, conclude this article without protesting against the assumption that the action of the alcohol present in malt liquors (which is generally pure and produced by internal fermentation) is to be altogether ignored in accounting for their therapeutic or dietetic effects on the system. If the extractive matter of malt liquors may "have the power of influencing the digestion of other food," may not the very moderate quantity of pure alcohol which they contain act in the same indirect and beneficial manner? Indeed, from time immemorial, wine, taken in moderate quantity at the principal meal, has been considered a promoter of digestion, an effect it may in many people of weak stomachs certainly lay claim to if only in virtue of its action upon the brain, for it will be generally admitted that exhilaration of spirits and a happy frame of mind are very favourable to digestion. But whatever its *modus operandi* may be, action of some sort, good or bad, it must have; it cannot be inert; and therefore, in those cases in which Hoff's malt extract, or any other malt liquor, has been found to benefit patients suffering from faulty nutrition, it may be presumed that the alcohol which they contain has at least some share in producing that effect.

PROGRESS OF THE NEW MEDICAL BILL.

Last Friday the Medical Acts Amendment Bill was read a third time in the House of Lords and passed. It is to be hoped that it will not meet with much opposition in the House of Commons, but if it does, it will be from that party which is so anxious at this critical period in the history of medical reform, to compel the Government to adopt measures which would be both unwise and impracticable at so late a stage of the passing of the Bill. We are far from finding fault with the general agitation in favour of altering the constitution of the General Medical Council, but we doubt the propriety of urging such a step at the eleventh hour, and on the very eve of the passing of a Bill in virtue of which the profession and the public will have secured the adoption of a scheme of medical education and examination which has long been contended for, and which cannot fail to have a very beneficial influence upon the future status of the medical profession. Not only do we think it desirable that the proposed reconstitution of the Medical Council should take place for the reasons that we and our contemporaries have already given, but on other grounds also. For in all probability the Medical Council will see the necessity of undertaking the duties imposed upon it by the Bill, namely, that of regulating the course of medical study and exercising some supervision over the examinations, and even of reporting to the Privy Council any examining body which fails to carry out the provisions of the Act. Now considering that ninty-nine per cent. of the candidates who will come up to the conjoint boards are destined to enter upon general practice, it is advisable that a portion, however small, of the examiners constituting those boards should be drawn from that class of practitioners which is most familiar with the exigencies of general practice. But the propriety of adopting such a plan would be more evident to a medical council, and would be more likely to be supported by it were it composed partly of members who directly represented the great body of general practitioners than were it to continue to consist entirely of members who are engaged in consulting practice. The direct representation of the profession in the Medical Council is therefore both desirable and practicable, but not at this present time. The incorporation of such a medical reform in the Bill now passing through both Houses of Parliament is impossible; and any opposition to the Government Bill on the grounds that it does not grant all that is asked for is neither politic nor likely to be successful. If the constitution of the Medical Council is to be changed, that change had better be postponed to a future occasion when it can be more conveniently and deliberately made. The present Bill is a great move in the right direction, and there is no reason why the reformation so well begun should not before long reach a point that will satisfy the most ardent medical reformers.

DEPARTMENTAL DESPOTISM.

It has been our duty—one which we would rather not fulfil—to call attention more than once to the high-handed method which the Irish Local Government Board has occasionally adopted in dealing with its medical officers, and we find it necessary to present our readers with one more specimen of the mode of doing business by that de-

partment, which we put on record in the hope that it may prove to be the last evolution of a policy which we trust is fast going out of fashion. We can sympathise with the anxiety of a public department to administer its regulations with firmness and prompt effect, but we cannot hesitate to express disapproval when an arbitrary or vindictive spirit is displayed, or when the authority wielded by such a department is misused and the letter of the regulations set at nought.

In the *Ballyshannon Herald* we find a letter, in which the following narrative is contained :—

"The medical officer at Doochary was, in due course, requested some time since to attend the petty sessions to give evidence in certain prosecutions for neglect of vaccination. He did so attend, and having given his evidence he applied to the magistrate for a certificate for his fee in accordance with the Act of Parliament. The magistrate refused, and, therefore, the medical officer received no remuneration whatever for his trouble in travelling a distance of nearly ten miles and giving testimony. On the next occasion on which the medical officer was requested to attend for a similar purpose, he did so, but, upon being called into the box, he pointed out to the magistrate that attendance at these prosecutions was no part of his (the doctor's) duty as set down in the regulations, but, on the contrary, was recognised by the law as a service to be paid for outside his dispensary salary. On the magistrate again declining to give the certificate the doctor declined to give evidence, and the cases were accordingly dismissed. Now comes the strange part of the story. The guardians having complained to the Local Government Board of the doctor's refusal, that Board wrote to the doctor demanding his resignation of his dispensary, but, knowing perfectly well that the giving of evidence at vaccination prosecutions is *not* a part of the medical officer's duty, and feeling that it would be totally illegal for them to dismiss him for refusing to perform for nothing, a service for which the law awards him a fee—the Local Government Board were driven to seek some other excuse for 'serving him out.' This they thought they found in an official report made by the doctor to them four months ago upon the sanitary state of his district, in which report the medical officer had stated roundly that the Public Health Act (as at present administered) was a sham, and a disgrace to the authorities. Everyone knows that the said Act is a sham, and the execution of it a complete farce; yet, for stating that fact in very emphatic language, the Local Government Board takes upon itself to punish the medical officer by taking from him his means of livelihood and subjecting him to professional disgrace.

"On his expressing regret for the phraseology used in his official report, the Board has reinstated the medical officer, but they cannot as easily efface the feeling of bitter disapproval which their despotic and unjust proceedings has evoked. It is, I submit, disgraceful to a public department: Firstly, that it should attempt to force unpaid duties on a member of any profession—knowing well that it cannot legally do so. Secondly, that, being foiled in that attempt, it seeks then to wreak its vengeance on its own officer by taking up a communication which four months ago it had received without any sign of disapproval."

We have thought this narrative worthy of special inquiry, and, without having the documents before us, we are in a position to state that the facts are accurately stated, and that no circumstance has come to our knowledge capable of excusing in any way the extraordinary course adopted by the Local Government Board.

We have reason to believe that the phrases used by the medical officer in describing the working of the Public Health Act were neither choice nor elegant, nor—in style—quite respectful to his masters. It is obvious, however, that they cannot have been so markedly objectionable as to attract notice or call for decided censure, for we find that they were not considered deserving of mention by the Local Government Board for four months after their being penned.

The act of the Board thus recorded was simply an attempt, illegally, to force upon medical officers in general, and upon Dr. Thompson in particular, a function—laborious and irksome—which the Board well knows is not equitably or legally his duty, and to wreak vengeance upon him for his non-compliance by the discreditable expedient of raking up a long past peccadillo. We beg the Board not to entertain the idea that by their move they have either established a principle or achieved a victory. They are truly entitled to all the honour of having intimidated a poor dispensary doctor into an humble apology, and of having, probably, frightened him into promising performance of anything or everything the Board pleases to put upon him. They have not, nor can they give themselves authority to coerce their officers to do anything but that which is their legitimate business, and for which they are paid; nor can they assume the privilege—not confirmed to them by any Act of Parliament—to dismiss an officer at their own caprice. On an occasion, not long past, they have indulged themselves with a similar threat, and it was our duty to remind them that they are not the sole judges as to what constitutes "sufficient grounds" for dismissal. We assert distinctly that no language in reference to the Public Health Act, short of actual disrespect, and no refusal of a medical officer to give evidence at a vaccination prosecution, constitute "sufficient grounds" required by the Act of Parliament as a condition of his dismissal; and we tender our respectful advice to the Irish Local Government Board not to be tempted into a display of hastiness of temper, such as this transaction indicates, until it is quite certain that its proceedings are outside the range of legal retribution and public criticism.

THE CRISIS IN MEDICAL AFFAIRS.

We are not, we conceive, guilty of exaggeration when we express our conviction that the medical profession is, at this moment, in the crisis of a revolution more portentous than that which medical affairs have undergone for half a century, and we recognise in the present circumstances of medical legislation the presence of interests of the gravest importance to the public while they involve the very existence of the medical profession as it has hitherto existed. It is well known to every medical man who interests himself in such matters that at length the abuses of medical qualification which have arisen out of the greed of licensing bodies and the incapacity of the General Medical Council, have culminated in the effort now being made by the Government to put medical education on a sounder footing, and that the profession has, almost with one voice, spoken loudly in favour of the means by which the Government has proposed to effect that object. It was proposed—speaking shortly—to compel the licensing bodies who have been hitherto selling diplomas upon whatever terms, educational and monetary, pleased them, to join together in the formation of a system by which the terms of granting licences should be uniform throughout the kingdom, and should guarantee the perfect competency of the practi-

tioner. Such objects were especially entitled to the warm approval of those who were conversant with the evil results of competition for the diploma fees amongst nineteen separate licensing bodies, and, as we have said, it received that approval with all the acclamation which it deserved. Thus, the Bill of the Duke of Richmond had, with the improvements suggested by the profession, secured the solid and hearty support of our profession, and (although it lacked one addition which had been earnestly hoped for) it would almost certainly have passed Parliament.

In the full enjoyment of our hopes of speedy medical reform, to the consternation of all reasonable advocates of that object, the Bill has assumed a character which makes its further support by the profession very questionable. As we have said, the plan of the measure was, that the existing licensing bodies should assist each other in the holding of examinations, one board of examination being formed for each country, and the education and examination under each being equal. The student having passed one of these Boards could not yet enter into legal practice, but should present himself to two licensing bodies which he selected, and receive from them his diplomas, on which he would be entitled to insertion of his name in the Medical Register and to the consequent privileges of practice. The amendment to which we refer was that introduced at the suggestion of the Marquis of Ripon, and referred to in the following Parliamentary report from the *Times* of June 4th :—

MEDICAL ACT (1858) AMENDMENT.

Their lordships having gone into Committee on this Bill,

On Clause 4, which would have made it necessary for a person who had passed the joint board examination to obtain a medical diploma from one of the existing medical authorities before he could be placed on the Medical Register,

The Marquis of Ripon moved an amendment to make such diploma unnecessary for the purposes of registration.

The Duke of Richmond and Gordon approved the amendment.

The amendment was agreed to, and Clause 4 as amended, and the remaining clausee, after verbal amendments, were ordered to stand part of the Bill.

The Bill was then passed through Committee and reported to the House.

Under this simple form lies a proposal which, we state without hesitation, signifies the extinction of the licensing colleges, and nothing else. Under the Bill, in its original form, these institutions should content themselves to suffer a serious loss of income, but this proposal would, we repeat, be equivalent to the reduction of the colleges to the condition of impecunious and insignificant medical clubs. By the Marquis of Ripon's amendment, the student who succeeded in passing the conjoint-board examination would be entitled, then and there, to register his passing and enter into practice. He need not, nor would ten per cent. of the students so qualified, ever think of entering a college or seeking a collegiate diploma until, if ever, the time came for him to look for a higher degree *e.g.*, a Fellowship or a Doctorate in Medicine. We are at a loss to conceive how there can be any doubt upon this point in the mind of anyone who knows anything of the matter, and yet we find the *Medical Times and Gazette* expressing its opinion that "the medical authorities will not object to the alteration, for no medical man will be likely to be content with the qualifying certificate only." As a matter of fact, it is true that fully nine-tenths of the students who enter the profession at the present day are "content with the qualifying certificate only," and never dream of seeking the higher diplomas, and there is not the remotest reason to suppose that the rank and file of the profession will ever see the necessity of passing and paying for distinctions which carry with them no legal privileges which they do not already possess. Deprived thus of their income from licensing, in what condition will the corporations stand? As a single example let us take the Irish College of Surgeons. In the past year it received £2,801 8s. from candidates for its license, and only £273 from its Fellowship candidates. If deprived of this £2,801 it would have only £873 left to meet an ordinary expenditure of £3,674 (exclusive of extraordinary building outlay).

Can the complete extinction of the Licensing Corporations be contemplated by the Duke of Richmond—the minister of a Conservative government. We can hardly conceive that it is so ; and we have, perhaps, spoken in ignorance of some scheme contemplated by the Duke to meet this difficulty. Perhaps it may be intended to fix in the Bill a fee payable for the Conjoint Examination Certificate, which will be adequate — when divided between them—to maintain the present Licensing Bodies. Nothing less than thirty guineas would suffice for this purpose, even though the Bodies submit to a serious curtailment of their present incomes ; and while we find mention of this or any other sum in the Bill, we anticipate that the prevailing idea in the Medical Council would be to fix the certificate fee at the minimum amount which would pay for the examination, and thus to leave no surplus for division; and it would be, therefore, out of the question to leave the fixing of such a detail to the discretion of the Council.

Radicals in Medical Reform may, perhaps, argue that it is not the duty of the State to take cause for the maintenance of Medical Corporations, and that it would be unjust to tax the immigrants into our profession for such purpose, but in this argument lies the gravity of the situation which we have said cannot be exaggerated. It may, indeed, be of little interest to the public whether Medical Corporations continue to exist or not ; but it should be remembered that the medical practitioners who treat the diseases of the public can hardly be taught their business without these institutions. It is the licensing bodies which maintain museums, keep medical libraries, provide laboratories and lecturers, and act as the motive power in encouraging medical research, and we find it difficult to imagine the system which can, under present circumstances, supply their place. The very Conjoint Examining Board which the State now recognises as the only legitimate portal to the profession are to be created mainly by those bodies, and, without their aid, the emoluments of teachers can never be sufficient to attract the best class of men in the profession for the instruction of the medical man of the future. The many reasons which may be given for the protection of the licensing corporations are, indeed, un-

necessary for us to detail here, and are so obvious that we cannot believe that the Duke of Richmond has overlooked them. We must assume, therefore, that he has failed to appreciate the effect of the amendment, and we most anxiously look for such a retracing of the step as may reassure the profession, and permit of their continuing their cordial support of the Bill. On the whole it seems to us that the purpose of the amendment would be most readily made compatible with the continued efficiency of the licensing bodies, by the fixing in the Bill of a uniform conjoint diploma fee for the whole kingdom, sufficient in amount to ensure the existence of these bodies and to make certain the social status of the profession in the future. It is quite certain that an alteration in the Bill to such effect must be made in committee in the House of Commons, otherwise the whole energy of the licensing bodies, backed by the influence of a large majority of the profession, will be used to prevent its becoming law. Hoping as we do for a reasonable measure of reform, we should feel its defeat to be a disaster.

Notes on Current Topics.

Temperance Coffee Taverns and "Temperance Stalls."

At the annual meeting of the East-end Juvenile Mission, known as Dr. Barnardo's Homes, held last Wednesday at Exeter Hall, the Lord Chancellor, who presided on the occasion, remarked that "Dr. Barnardo was the first to institute the system of temperance coffee-houses. He was able in the East-end to secure a magnificent gin palace and a large shop. They were fitted up in an extremely attractive way, and there the working-man escaped the ruinous temptation to drink which had been the curse of the metropolis. One of those coffee palaces during the year had realised a sum of £2,300, its expenses amounting to £2,000. In the mission rooms there were evangelistic addresses, and he had himself seen one of these rooms crowded from end to end with most anxious and inquiring auditors to hear a plain, simple address, which had nothing in it to attract except the truth and simplicity of the Gospel. It had been determined to add a medical mission, through the exertions of which there would be a power of carrying the message of the Gospel to people whom they could not otherwise approach."

There can be no doubt that the establishment of these attractive and well-conducted coffee-houses is one of the best means that could be adopted to check the enormous amount of intemperance prevalent in the metropolis; and therefore we are glad to see that the establishment mentioned above has turned out such a success. In connection with these places, we may also notice the "temperance stalls" that are springing up in different parts of the town. They are simply covered refreshment stalls similar to those seen on the Continent, supplied plentifully with tea, coffee, lemonade, &c., but no intoxicating liquors whatever. By such measures we may hope in time to see more good done in the cause of temperance and towards repressing the drunkenness of the working-classes than all the lectures and demonstrations that are being continually given in favour of the "total abstinence" movement and the absolute proscription of all kinds of alcoholic beverages under any circumstances whatever.

We hear that a case of fever, which is so general at Gallipoli, has made its appearance on board H.M.S. *Rupert;* and her commanding officer, Captain Gordon, has been sent to Malta Hospital for treatment. With this exception, the health of the fleet in the Dardanelles continues good.

Dental Druggists.

The surgeons who practise dental surgery are likely to realise the consummation which they appear to desire, *i.e.*, the honour of appearing in the same official register hobnobbing in professional circles with the oilman in the next street; at least we learn from the *Pharmaceutical Journal* that such a happy condition of amity is contemplated by the drug trade. In the last issue of our contemporary we find the following statement:—

> The Dental Practitioners Bill, as amended in Committee, now contains an addition calculated to provide that recognition of the rights of chemists and druggists who have been engaged in the practice of dentistry, which we have already pointed out it was only reasonable to expect. This clause, as it now stands, provides that among those who are to be entitled to registration, and subject to that formality, exempt from the penal provisions of the Bill, are to be included persons who at the passing of the Act are *bonâ fide engaged in the practice of dentistry in conjunction with the practice of pharmacy.* We may therefore regard this matter as being virtually settled by the Pharmaceutical Society *on behalf of the trade interests of the body it represents.*

It may be an additional satisfaction to the members and fellows of Colleges of Surgeons who are to share with their druggists the distinction of the Dental Register, to learn that any oilman can satisfy the requirements of the Bill and prove himself to be "*bonâ fide engaged in the practice of dentistry*" by a certificate given *by himself to himself,* a testimonium of a single day's experience being sufficient to justify the declaration. In other words the druggist may put a drop of creasote in a hollow tooth on the 31st of December, 1878, and he will be perfectly entitled to state that he is "engaged in the practice of dentistry," and will be then and there co-opted and officially recorded a practitioner of dental surgery on the 1st of Jan., 1879.

A more astonishing piece of legislation never existed, and yet it seems likely to pass in consequence of the complete apathy of the licensing bodies, and, more extraordinary still, of the dental surgeons.

In the House of Commons, last week, in Committee on the Bill, on Clause 22, Mr. Young moved an amendment with a view to restrict the uses of the terms "surgeon dentist" and "dental surgeon" to practitioners who had the qualification of a surgeon. The amendment, he said, was supported by high medical authority.

Sir J. Lubbock said that as the description "surgeon dentist" was legal under the common law, and had a generally accepted meaning, which, according to the Lord Chief Justice, was well understood, those who drew up the Bill did not think it necessary to complicate the matter by introducing such an amendment.

The Chancellor of the Exchequer desired to consult the

President of the Council, and would therefore defer any expression of opinion until the stage of report. He was under the impression that an amendment had been made. However, it was not necessary to make one, as the Bill could be amended if thought desirable in the other House.

Sir J. Lubbock said *no medical body had petitioned in favour of this amendment*, which, therefore, had only received individual support.

The amendment was negatived.

The Bill passed through Committee.

Medical Expert Testimony.

An able article upon this subject appears in the *Medical and Surgical Reporter*, April 20, 1878, from the pen of John J. Reece, M.D., Professor of Medical Jurisprudence and Toxicology in the University of Pensylvania, &c.

It deals at length with the questions: 1st. The qualifications of those who may claim to be considered *experts*; 2nd. The justice or injustice of calling upon experts to give their opinions in any given case, without special and adequate remuneration. With regard to the first of these two questions, Dr. Reece points out, what seems on the very face of it a self-evident truth, that no one should be called upon to express an opinion as an expert, or to put himself forward as one, unless his whole life's study has been specially directed to that particular branch of knowledge within the scope of which the point at issue falls, and in connection with which the witness's eminence has been very generally admitted. The author emphasises the fact that neglect of this rule on the part of medical men themselves has often led to able men being placed in a very false position, and to medical evidence in general being brought into great discredit.

He very properly insists that "expert" evidence should be given in a spirit of strict neutrality; that it should be based upon a calm and unbiassed consideration of all the known *facts* of the case in question, and upon that alone.

With regard to the second question, he argues—and argues, we believe, very justly—that "expert testimony" is the private property of the witness, and that it is most unjust to expect such evidence to be given without special and adequate remuneration; that the evidence is not one of facts necessary to the ends of justice, which the witness as a good citizen of the State is bound to supply, but of *opinions*, of skilled knowledge, the result of special study and experience, which special knowledge is the private property of the witness by which he lives, and to which neither private indivividuals nor the State have any right, unless proper remuneration has been made.

A New Qualification for a Coroner.

It having been stated that Dr. W. Murphy had resigned the coronership of East Limerick a number of candidates are seeking the office. Among these is Mr. Casey, who was recently prosecuted for having written newspaper letters under the name of "the Galtee boy," which were calculated to incite to the assassination of the agent to the Galtee estates. He is making an energetic canvass, and has been received with great enthusiasm as "the defender of the poor mountaineers." He made recently a speech in which he said he sought the only office left in the power of the people to dispose of as a recognition that he had done something for the tenant farmers and shown to the world the wrongs and oppression suffered by the yearly tenants of his oppressed land.

Accidental Poisoning of a Child by Strychnine.

An inquest was held a few days ago before Dr. Mitchinson, at West Barkwith, Lincolnshire, on the body of a male child, aged two years. It appears that the mother of the child while clearing out a cupboard placed a few partly empty medicine bottles on the table, and when her back was turned the child drank some of the contents of one of them, which was supposed to contain a solution of quinine. About a quarter of an hour afterwards deceased suddenly became convulsed, and screamed violently, as if in pain. Its hands became clenched, and body very hard and stiff. With the aid of a neighbour the mother put the child into a warm bath and gave it an emetic, and sent for Dr. Armstrong, of West Barkwith. On his arrival he found the child suffering from the symptoms of poisoning from strychnine. He applied the usual remedies, but death rapidly ensued. Dr. Harrison took possession of the bottle from which the child was supposed to have taken the poison, and telegraphed to the London chemists who had prepared the medicine for Mrs. Thompson, who in reply informed him that it was a solution of strychnine which had been furnished to a lady some six or seven years ago.

There is nothing very remarkable about the case with the exception of the fact that the bottle, although coming from a first-class London chemist, did not have a poison label on it. This was a most dangerous and culpable piece of neglect on the part of the chemist, considering the bottle contained one of the most powerful poisons known. Moreover, poisoning by strychnine at so early an age is comparatively rare. In this case it was supposed that the child took about half a grain of the poison, and he lived only an hour and a half after taking it.

Mr. John Parry.

We think that our medical *confrères* might take a lesson from the unfortunate position of a gentleman to whose talents the public have been for many years indebted for much refined amusement. It appears that a large part of Mr. Parry's property, the fruits of his professional labours, was entrusted to his solicitor for investment. The recent death of that gentleman has disclosed the lamentable truth that the money was never invested in the manner represented, and it is to be feared that little is likely to be rescued from the winding up of the estate. A fund is being raised by various influential friends of Mr. and Mrs. Parry to save them from the great distress to which, in their declining years, they are likely to be reduced, and we hope that liberal subscriptions will be forthcoming to fulfil the very desirable object in view. In the meantime we draw the attention of our readers to the case as showing that our duty to ourselves and our families does not end with merely entrusting a large sum of money

to a solicitor for investment. We should also make a point of seeing some proof that the money has been invested in the manner represented, and even of having ourselves possession of the bonds or certificates received in acknowledgment of the investment. Members of the medical profession are not, as a rule, good men of business; their professional earnings, and still less their savings, do not generally amount to very much, and their necessary expenses are often very great. They cannot, therefore, be too careful about the little capital they may possess, so that it may be properly and safely invested without any risk of its being lost through the misfortune, negligence, or dishonesty of other parties.

A City of Health.

Dr. Elliot, the Medical Officer of Health for the city of Carlisle, must lie on "a bed of roses." According to his last report for the Carlisle Urban Sanitary District, ending May 30th, the death-rate was at the rate of only 8 per 1,000 per annum. In the corresponding week of last year, the death-rate was 24 per 1,000 per annum. Frequently the death-rate of Carlisle has been singularly small in the course of the last two years. It has been repeatedly down to 11 per 1,000, but the rate of 8 per 1,000 was not only lower than ever previously known, but such a rate is probably lower than any town in existence, with a population of 35,000, a fact all the more remarkable when the great antiquity of the city is considered as entailing sanitary disadvantages which can only be very slowly remedied. Of course, correct inferences cannot be drawn from any single week's results, but such a fact is, at least, extraordinary.

Competitive Athletic Examinations for the Army.

In the House of Lords, on Friday, Lord Hampton moved for the report of the joint committee of the War Office and the Civil Service Commissioners, appointed to consider the question whether the present literary examinations for the army should be supplemented by physical competition In the course of his remarks, Lord Hampton said that those young men who desired to enter the army should have the discretion of selecting three out of six manly exercises in which success in examination should bring them a maximum of 1,200 marks. We have all along so strongly insisted upon the propriety of giving more attention to the physical education of the army, and of developing the physique of both officers and men by the systematic introduction of all kinds of athletic sports and exercises, that we heartily sympathise with the feelings expressed on the subject by those noblemen who took part in the debate on Lord Hampton's motion. They all agreed that if this physical examination were made part of the examination for the army, it would be an additional safeguard that we have the best and finest men in her Majesty's service. But Earl Grey's reason for supporting the proposed change was still more to the point. It was not only, he said, extremely important that persons liable to be engaged in warfare should have their bodily powers cultivated, but so keen was the competition to enter the army, it was very desirable to adopt some change in order to counteract the dangerous tendency to undue stimulation of the mental powers. The justness of these remarks will be duly appreciated by the profession whose attention has been too frequently drawn to the deplorable effects of overtaxing the brain in the hopes of passing some competitive examination. It is evident that a candidate for a commission in the army may pass the ordinary medical examination, and yet may have so injured his mental and bodily vigour by the severe mental strain that his studies have imposed upon him, as to be incapable of afterwards reaping those advantages that are inseparable from the possession of a good constitution. It is natural that such an innovation as that proposed would be received with a certain amount of suspicion, but the criticism which the subject elicited turned more upon the method of carrying it out than upon the principle it involved. Lord Cardwell said the subject was a difficult one, and reminded the house that in modern warfare the principal secret of success was intellectual efficiency. But in answer to this we would say that it is intellectual efficiency of a peculiar kind, not that which is the outcome of mere book-learning, but that which results from the duo exercise and gradual development and improvement of both the intellectual and physical powers, and whose final expression is that sound judgment, clearness of intellect, self-possession, readiness of resource, and good common-sense, which are so characteristic of the smart and intelligent officer, or successful general.

The Army compared with Civil Practice.

We published recently the letter addressed by the War Secretary to the Irish Medical Schools, in which information was requested respecting the earnings of civil practitioners during successive periods of their professional career—it being desired to contrast the financial position of the Army Medical Officer with that of the Civil Practitioner. To this letter the Professors of the School of Physic of the University of Dublin have sent the following reply:—

Trinity College, Dublin,
May 23, 1878.

Sir,—I am instructed by the Professors of the School of Physic in Ireland to express their regret that it is not in their power to give a detailed answer to Secretary Colonel Stanley's letter of 27th ult., as they do not possess the data necessary for such an answer.

The Professors, however, desire to make the following statement, for the information of Secretary Colonel Stanley:—

The medical graduates of the University of Dublin are all obliged to undergo, in addition to the usual training in medicine and surgery, a further liberal training in arts, during four years; as it has been the invariable practice of the University of Dublin to require graduation in arts as a necessary preliminary to graduation in medicine. In consequence of this practice, the medical graduates of the University of Dublin possess an education superior to that of the medical graduates of Universities not requiring degrees in arts, and, of course, superior to that of licentiates and members of the Colleges of Physicians and Surgeons.

It thus comes to pass that our graduates are entitled to seek, and do seek and obtain, positions in civil practice, from the outset of their career, superior to the ordinary Poor-law appointments open to the competition of all registered practitioners in Ireland.

Even these appointments are, on the average (including emoluments as well as salaries), worth £145 per annum; a sum which a moderately well-educated man would, in most cases, from the outset, convert by private practice into double that amount, with prospects of still further increase, varying according to the locality.

The higher class of appointments open to our students are worth fully £500 per annum.

Any desire to enter the Army Medical Service, which existed on the part of the graduates of the University of Dublin, did not depend on financial reasons, but on the popularity of the Army Service itself among all classes of educated Irish gentlemen.

The causes referred to in our letter to Mr. Secretary Hardy of 18th ult. have rendered the Army Medical Service distasteful to the feelings of educated gentlemen: and this class of candidates will not come forward in large numbers until the social disqualifications attaching to the Army Medical Service are frankly removed, and the medical officer admitted to a full equality with the combatant officer in social rank and position in the Service.

I am instructed, finally, to state that it is the opinion of the Professors of the School of Physic that if the examinations for the Army Medical Service included a large element of classics and science, as well as of medicine and surgery, a better class of army medical officers would be at once secured; and all difficulty on the part of their brother officers to concede them equal social privileges would disappear, in consequence of the superior education of the medical officers selected under such a system. The improved examination here suggested would continue to be, as the present examination is, competitive.

I have the honour to remain,
Your obedient Servant,
SAMUEL HAUGHTON, Clk., M.D.,
Medical Registrar.

Ralph Thompson, Esq., C.B.,
Under-Secretary of State for War.

The Local Government Board and Dr. Meehan, of Kilmallock.

IT will be recollected that the Local Government Board refused to sanction the appointment of Dr. Meehan (who had suffered sentence in connection with the Killmallock insurance frauds), to the Limerick Workhouse, and on the Board of Guardians remonstrating against this refusal, they threatened a sealed order if the appointment of another person were not proceeded with. It would seem that the Local Goverment Board has had occasion to reconsider the matter, for at the last meeting of the Board of Guardians the following letter was read :—

Local Government Board,
Dublin, 4th June, 1878.

SIR,—With reference to the recent removal of Dr. Meehan from the office of visiting medical officer of the workhouse of Limerick Union by sealed order of the Local Government Board for Ireland, I am directed to state for the information of the Board of Guardians that the Chief Secretary of the Lord Lieutenant is in communication with Mr. Butt, M.P. for Limerick, on the subject, and that he is desirous nothing further should be done in reference to the case until he has had a full opportunity of making to him any further statement which he may have in view, although at present the Chief Secretary has no reason to question the correctness of the decision arrived at in Dr. Meehan's case.

By order of the Board,
B. BANKS, Secretary.

After a warm discussion the board decided, by a large majority, to postpone the election of a resident medical officer and a resident apothecary, pending the inquiry, which it was intimated, the Chief Secretary was instituting into the case of Dr. Meehan.

The Health of Dublin.

THE health of the city shows (for the week ending June 1), a sudden and great improvement. The mortality rate has fallen to 25·1 per 1,000 of the population. The small-pox deaths were the same in number as those of the preceding week, but the admissions to hospital had fallen to 70 (or 24 less than the previous week) and the cases in hospital to 239 or 28 less.

Hereditary Transmission.

A CORRESPONDENT, in our contemporary, *Nature*, reports a curious case of hereditary transmission in a slave. "Capt. D'Urban, of H.M.S. *Griffin*, having captured off the south coast of Martinique a Portugese slaver, called the *Don Francisco*, landed in this colony the living freight of 437 human beings, who, about two months previously had been forced from their homes on the banks of the Congo, to be sold in Cuba. William Laidlaw, one of the liberated slaves, gives to me the following interesting details of hereditary transmission in the African, which I believe will be interesting to the readers of *Nature* :—

"'I am about sixty or sixty-five years of age, and was born with six fingers on each hand. Soon after my "freedom," I married a woman from "our country." We had four children, two being boys and two girls; they were born with six fingers on each hand, and one of the girls had six toes on each foot. My eldest son, Robert, who is married and settled in Demerara, is the father of two boys, whe have six fingers on each hand. My second son, William, who is working with me on the Goodwill sugar plantation, married, and his wife had five children; they were born having the same peculiarity, but I regret to say none are living.'

"I yesterday sent for William Laidlaw, and have substantiated his father's statements. I measured the sixth fingers; the one on the right hand is exactly 1¼ inch in length, and has a perfectly formed nail, the one on the left showed traces of having been partially amputated."

Throat and Ear Hospital, Dublin.

DR. POPE has been appointed one of the medical officers of the hospital, in the room of Kendal M. Franks, M.D., who has been appointed surgeon of the Adelaide Hospital.

IN view of the new charter, enabling the University of London to confer degrees on women, and the increased demand for the higher education of women, the Council of University College have determined to provide for them systematic instruction in regular college classes. In most subjects the junior classes for women will be distinct from those attended by male students. The senior classes will more generally be open to both sexes, and those classes which are already open to both—as Fine Arts, Philosophy of Mind, &c.—will remain so.

THE annual rate of mortality in the principal foreign cities, according to the most recent weekly official returns, were in Calcutta 40, Bombay 43, Madras 46; Paris 23; Geneva 22; Brussels 26; Amsterdam 27, Copenhagen 22; Stockholm 29; St. Petersburg 57; Berlin 27, Hamburg 27, Dresden 28, Breslau 32, Munich 35; Vienna 38, Buda-Pesth 43; Rome 28, Naples 37, Turin 34, Venice 28; Alexandria 40; New York 22, and Philadelphia 18. The 726 deaths in St. Petersburg included 158 from fevers.

PROF. VIRCHOW, of Berlin, believes he can furnish proof from a Bulgarian skull, that the Bulgarians are not of Slav, but of Turkish origin. For this purpose Herr von Hönika will shortly bring from Roumania fifteen skulls of Bulgarians who were killed by the Turks near Kadikoi, and which have been prepared at the request of Herr von Hönika by Dr. Markovics in Sistova.

THE Russian troops appear to be still in a most unhealthy state. From Helsingsfors we learn that the sickness in the Finnish battalions of the Guards has increased rather than diminished since their return from the war. Every day new cases arise. Spotted typhus prevails, though it has not yet appeared outside the barracks. The soldiers are to be put under canvas outside the town.

THE death-rate throughout the United Kingdom was again exceptionally low last week, being 21 per 1,000 in London, 22 in Glasgow, 24 in Edinburgh, and 25 in Dublin. In the other large towns the majority were below these figures, the highest being Sunderland with 27 per 1,000 of its population.

THE mortality from small-pox again declined in the metropolis last week to 40. Of these, 20 were certified as unvaccinated, 11 as vaccinated, the remainder being uncertified. There were 15 deaths from this disease in Dublin, and 1 in Sheffield, no others being reported.

Correspondence.

"ON BLOOD-LETTING AS A THERAPEUTIC."

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I have just read with much pleasure a letter on the above subject in yesterday's issue of your journal by Mr. O'Flanagan. The able writer of that letter has stated what it has been his lot to witness with a most commendable frankness. He lives in a district where acute diseases are most likely to be common enough, and, therefore one in which such a remedy as blood-letting can be fairly tested. I have nothing new to add to what Mr. O'Flanagan has set forward, but am writing for the useful purpose of corroborating that gentleman's experience by what it has been my own fortune to behold. When I assisted Mr. Crockett, Chief Surgeon, Cyfarthfa Iron Works—a gentleman both brilliant as an operator, and painstaking and accurate as an observer, I had abundant opportunities of testing the efficacy of blood-letting in such diseases as Mr. O'Flanagan makes mention of, particularly hepatitis, nephritis, pleuritis, and pneumonia, and the conclusion that forced itself on Mr. Crockett, as well as on myself, was, that sooner or later the enlightenment which facts necessarily create would be as powerful in reviving blood-letting as a most valuable therapeutic agent, as prejudice, if not ignorance, had been in effecting its decay. I have witnessed truly marvellous results from this topical remedy—results as comforting to the patient as they were agreeable and encouraging to ourselves—in nearly all of the diseases mentioned by Mr. O'Flanagan.

I am of opinion that leeches have been cast too much into the shade by practitioners in this country, and can vouch for the persistence in, and the success of, the judicious use of leeches by general practitioners in Ireland. I trust, therefore, that Mr. O'Flanagan's letter may be the means of stimulating scientifically-disposed practitioners to give to blood-letting a fair trial, and to the profession at large what I confidently anticipate, the favourable result.

And setting aside the subject matter itself, permit me, Sir, to call the attention of your readers to the simple, yet admirable style in which Mr. O'Flanagan's letter is written. At present a good deal is being written about what constitutes the educated physician, but my opinion has always been that the capacity and literary taste of the man himself and not the degrees which he may have obtained, make up what is called "the man of learning." No cramming in the collateral sciences, nor getting off translations of the ancient languages can compare for one moment with the immeasurable advantages to be derived by a careful study of the writings of Swift, Goldsmith, and Addison. It is a standing disgrace to the general practitioner, and very often to the pure physician or surgeon that, of all other things, that of which he is most ignorant, is the simple use of his native language. Is such not deplorable? It is, however, a glaring truth. "Language is the armoury of the human mind, and at once contains the trophies of its past and the weapons of its future conquests." Such was the opinion of the immortal Coleridge, and in doing honour to this opinion, and in the endeavour to raise the profession in a literary, as well as in a scientific sense, let us cultivate our own language. Until we do this we can neither speak nor write with pleasure, and with but little advantage.

I am, Sir, your obedient servant,

38 Alton Street, Blackburn, May 30, 1878. JOHN LOWE.

ARMY MEDICAL SERVICE IN INDIA.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—At the present time when the wrongs of the Army Medical Department, are receiving such attention from the various Licensing Bodies in this kingdom, and when the military authorities are making such anxious but ineffectual bids to secure a supply of qualified practitioners for the service, the following extracts from the letter of an old pupil and friend of mine, now serving abroad, will command some interest, and throw some light upon the treatment which aspirants for medico-military honors are to expect.

I am Sir, your obedient servant,

W. THORNLEY STOKER,
Prof. of Anatomy, Royal Coll. of Surg., Ireland.

"You will be surprised to hear that after a year's service, and having gone through the session at Netley, we come out here to find we are only probationers. I send a copy of Surgeon-General Gordon's memo. on the subject, with the instructions from the Madras Medical Code, and we only receive rupees 317-8 a month, which is exactly the same as assistant-surgeons received ten years ago, when the pay at home was 10s. a day. I suppose we are to be treated as probationers for ten years, and receive the same pay all the time in India."

CONFIDENTIAL. Surgeon General's Office,
Cir. Memo., No. 4-78. Madras, 20th Feb., 1878.

The Surgeon General desires that the instructions contained in the Madras Medical Code, vol. i., sec. ii., para. 22, down to the words "Inspector-General's Office" in clause (*c*) be made applicable to young officers of the Army Medical Department.

2. The selections from the case-books referred to at clause (*c*) to be forwarded to the Surgeon General's Office B.M.S. Fort. Saint George.

3. Dr. Gordon also solicits attention to the remarks contained in his "Notes on the Hygiene of Cholera," chapter C. i. para 8, page 203.

By order (Signed),

G. B. MOUAT, M.D., Surgeon Major,
Secretary to the Surgeon General, B.M.S.

(*Extract from Medical Code*, vol. i., para. 22, sec. ii).

Instructions for Probationers.—The following detailed instructions relative to probationary duties are to be strictly observed by all concerned:—

(*a*) Assistant surgeons are directed to apply themselves to the study of Indian diseases, and their appropriate treatment. They are to observe carefully the practice of surgeons under whom they are placed, and they will be permitted to treat, under the strict supervision of the surgeon of the hospital, such cases, medical and surgical, as he may entrust to them.

(*b*) It is to be distinctly understood that the sole charge of severe cases of disease, where the preservation of the patient's

life depends on the treatment pursued, must not at first be entrusted to assistant surgeons doing probationary duty.

(*c*) Assistant surgeons will keep journals of their cases, according to established form, in their own hand-writing. Under ordinary circumstances, every case entrusted to their charge must be entered in the journal. The surgeon in charge of the hospital will consider it his duty to record in the probationer's journal such remarks as he may consider necessary on any of the cases, and to note any errors or omissions in the daily entries. At the end of every month, the assistant surgeon will make a selection of not less than six cases, which have been recorded in the journal, and submit them through his immediate superior to the deputy inspector-general of hospitals of the circle, who will transmit them to the inspector general, Indian Medical Department.

(*d*) The cases so selected should be fully reported, both as to diagnosis and treatment. They should be copied on sheets of foolscap paper, stiched together, folded, and docketted like other professional papers. It is especially directed that each monthly journal shall contain a full commentary on the cases treated, and that whenever cases have ended fatally, the pathological conditions of affected organs shall be fully noted.

(*e*) Deputy inspectors-general of hospitals are enjoined to inspect all probationary journals with particular care, and to enter their opinions in the way of comment on such points of practice as may appear to require notice. If the deputy inspector-general feels it necessary to enter critical notes on the journals, they are to be returned to the young medical officer, before being passed on to the Inspector General's Office.

COUNTY INFIRMARIES AND WORKHOUSE HOSPITALS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Such a long interval had occurred since my letter in reply to Dr. Laffan without any further communication on his part, that I was beginning to hope my arguments had satisfied his offended *amour propré;* such, indeed, seems to have been the case, as in his last letter to your journal he has left argument in the background, and has even failed to bring up fresh forces to the assault; I am, therefore, at a loss on what point to attack him. I must, however, premise any remarks I may have to make by an acknowledgment of the courteous tone of Dr. Laffan's letter, and I assure him he only does me justice when he retracts his former assertion, "that it was my intention to cast a stigma on the professional character of workhouse medical officers." As I have before said, nothing could have been further from my thoughts. I did, however, intend in my report to demonstrate some of the advantages infirmaries undoubtedly possess over the generality of workhouse hospitals, and some of the arguments I adduced in support of my statement will be referred to later on in this letter.

The compilers of hospital statistics must of course, as Dr. Laffan states, expect criticism, and criticism is just what we, the surgeons of the Irish county infirmaries, solicit. It is not, however, our object to disparage workhouse hospitals, far from it; but it is our anxious desire—not, of course, from any personal motive—to preserve intact the Irish infirmaries, and, in order to do so, it is necessary to keep prominently before the public the great advantages conferred by each infirmary on the county in which it is situated. It is in furtherance of this object that I have drawn up and published an Annual Report of the Tyrone County Infirmary, much to the satisfaction of the governors, and, I believe, of the public, many of whom had previously no idea of the work done in their county hospital. Dr. Laffan states that in your editorial note to his first letter, you and I are agreed, "that no reflections were intended to be made on the skill of the workhouse medical officers;" he holds, however, that such is not the meaning conveyed by my language, and, in support of his argument, he makes the following extract from my Report for the year 1877: "I briefly pointed out the disadvantages the patients labour under as compared with county infirmaries in the scientific treatment of medical, and especially of surgical, diseases, I endeavoured to point out the necessity for a central hospital in each county for the treatment of severe medical and surgical cases, and I drew attention to the irreparable loss the medical profession in this country would suffer by the general closure of county infirmaries." Now, Sir, Dr Laffan has omitted your words from the commencement of this paragraph, which alters materially its whole aspect; the words are: "In my previous report," *i.e.*, for the year 1876. On referring to this document, I find the following: "It seems to me a necessity that the respectable farmers, servants, and shop assistants should have some shelter when overtaken by severe illness, and it is impossible to expect them to avail themselves of the workhouse hospitals, the very name of which inspires a certain loathing, which, however we may regret, and which may appear uncalled-for, still exists. Besides, every county should have at least one central hospital where important surgical operations could be performed with some chance of success. In the workhouse hospitals, patients have not, indeed, cannot have, the same nursing and attendance that is absolutely essential in a well-managed hospital; they have not as many comforts, neither have they a resident medical officer, which is a necessity where important operations are undertaken." Is there here one word disparaging to the workhouse doctor? I can see none, and I am sure Dr. Laffan himself will be the first to admit that there is none.

In the concluding portion of his letter, Dr. Laffan states that your objection to the workhouse hospitals consists in the fact that severe surgical cases are scattered indiscriminately "'mid a crowd of lighter ones;" this is not so, as Dr. Laffan will see by a reference to your editorial note of the 24th ult., where you enumerate correctly many other reasons for your belief. Dr. Laffan is, however, much mistaken if he supposes that county infirmaries are merely receptacles for severe surgical diseases, where, according to him, these cases are collected "in one seething mass." A reference to the table of admissions to the Tyrone Infirmary for the past year will prove how much he is mistaken in this particular, as in others.

County infirmaries are doubtless central hospitals intended for the reception, not of trivial, but of severe medical and surgical cases, which require more than ordinary care and attention; it would, however, be a sad commentary on these institutions to suppose that their hygienic arrangements are so imperfect that the patients are necessarily congregated in one seething mass of human suffering. On the contrary, the Irish infirmaries are, as a general rule, well-found hospitals, furnished with all the necessary medical and surgical appliances that modern science demands, well-constructed, possessing every possible comfort that a good hospital can afford, having a fair system of nursing, and, above all, the hands of the surgeon being supported by an admirably constituted governing body, which, I much fear, present attempts at legislation will find it hard to improve, and not fettered by the fear of a board of guardians and their peculiar ideas of economy. Many other powerful arguments in favour of the maintenance of the county infirmaries could easily be adduced, but with what object? Surely enough has been said to prove—1st, That it never was my intention to call in question even in the slightest degree the scientific attainments of the Irish workhouse doctors; and 2nd, That county infirmaries possess advantages for the treatment of disease and injury that workhouse hospitals cannot possibly afford.

In conclusion, I beg to thank you, Sir, for your kindness in publishing this letter, which has reached an inordinate length; the importance of the subject, however, requires more than a mere passing notice.

Yours truly,

EDWARD C. THOMPSON, M.B.,
Surgeon, Tyrone Infirmary.

Omagh,
May 31, 1878.

Literature.

A TREATISE ON CHEMISTRY. (*a*)

NOTWITHSTANDING the redundancy of the smaller works devoted to chemistry, those which, from their copiousness, can lay claim to be considered as "treatises" on the science are really very few in number. Yet the rapidity with which successive editions of these more exhaustive works are absorbed shows that it is not so much for lack of readers as for lack of authors of sufficient energy and experience to furnish new ones, that such books are not more numerous. The growth

(*a*) "A Treatise on Chemistry." By H. E. Roscoe, F.R.S., and C. Schorlemmer, F.R.S., Professors of Chemistry in Owens College, Manchester. Vol. i.: Non-Metallic Elements. London: Macmillan and Co.

of the science of chemistry has been so rapid and so constant, and the records of its progress are so widely scattered, and written in so many different languages, that to produce a work which shall be really *au courant* with the times, and chronicle the more important advances in pure and applied chemistry, would require a mind of no ordinary grasp and a perseverance of no common standard. In the present instance the labour has not devolved on one man, but on two, who are colleagues at Owens College. The gentleman whose name appears first upon the title-page is well known for his many investigations in spectroscopy and inorganic chemistry, and has for years past paid much attention to applied chemistry, for the study of which his post as a professor of chemistry and technology in a manufacturing district like Manchester gave him ample incentive and opportunity; while the second—the professor of organic chemistry in the same college—is one of our most ardent workers in the field of organic research. Taking the names of Roscoe and Schorlemmer together, it is scarcely possible to have a better guarantee that all branches of chemistry will be adequately dealt with.

It is, however, somewhat to be regretted that in a work of the comprehensive nature this is evidently intended to become, and divided into volumes published at different dates, the authors should, in their preface, give no sketch of the plan on which their treatise is to be arranged, or of how many parts it is to consist.

The present volume (the only one yet issued) (*a*) has for its sub-head "Non-metallic Elements," to the study of which it is chiefly devoted. There is also an historical introduction and a chapter on General Principles, and, at the end of the volume, a chapter on Crystallography.

The "historical introduction"—a brief essay on the history of chemistry up to the present time—is a new feature in an English chemistry book, but the information given is well worth studying by those who desire to become scholarly chemists. The foundation thus laid is extended in the body of the work by the constant allusion to the names of the investigators, and by foot references to the original memoirs. Not only does this practice add weight to the information, and do justice to the original investigator, but it affords the student the opportunity, otherwise difficult of attainment, of referring back to the original paper should he require greater fulness of detail. So constantly do the authors recognise this, that one feels some little surprise whenever the authority is withheld. For instance, one would have liked to see Ansell's name mentioned as the originator of the "Osmometer" apparatus, described on page 86, for giving warning of the outbreak of fire-damp in mines. (*b*) Again, as being a fact we have not previously seen recorded, we should have been glad to see the authority given for the statement that Reinsch's well-known test for arsenic "can only be employed when the quantity of arsenic is present in considerable quantities, inasmuch as the greater part of the arsenic remains behind on the copper." We had ourselves always found Reinsch's test of considerable delicacy, while Dr. Wormley obtained a decisive sublimate from a solution containing but 1·10,000th of a grain. Speaking of this test in his "Micro-chemistry of Poisons" he says, "it serves to separate from complex mixtures, and reproduce in an unequivocal form a less quantity of the poison than any known test, excepting, perhaps, one of the methods of Marsh's process, with which, however, it is equally delicate."

The chemistry of the non-metallic elements is written in a condensed yet explicit style, suggestive of a professor's lecture notes, revised again and again; the subject matter is thus made most recent and complete. In fact, saving Watts's "Dictionary of Chemistry," we have no original English work which can compare with this book in the number of the compounds of the elements which are described. The instructions, too, for the preparation of all these bodies are unusually minute, and they are illustrated, when necessary, by woodcuts of the apparatus, or, in the case of great industries, by plans, sections, and elevations of the most modern "plant" in use.

Among the changes made by the authors in the chemistry of the non-metals, we notice that arsenic has been definitively added to their number. The atomic weights have been changed in accordance with the classical researches of Stas. Thus oxygen is no longer 16, but 15·96; carbon not 12, but 11·97; chlorine 35·37, instead of 35·5. Again, the manufacture of bleaching powder, usually treated under "chlorine," is to be reserved for the second volume, while urea, ethylene, coal gas, and a number of other bodies, usually described in the section on organic chemistry, are described in this volume.

A section which will be of interest to the medical man will be that on "natural waters;" and in it we notice two slips. After speaking of Frankland's and Wanklyn's methods of water analysis, it is stated that, "If now, by means of either of these processes, a water is found to contain more than 0·15 parts of albumenoid nitrogen to one million parts of water, it may be considered as unfit for drinking purposes." As a matter of fact, however, the results of the two methods cannot be put on the same footing, for by Wanklyn's process only about one-sixth of the total albumenoid nitrogen is evolved, whereas by Frankland's the whole is obtained. Thus, while Wanklyn gives 0·05 albumenoid nitrogen (equal to 0·06 albumenoid ammonia) per million, as the average amount in the London water supply obtained from the Thames, Frankland's average is about 0·32 per million (0·032 parts organic nitrogen per 100,000) from the same water; a difference of result which by no means bears out the statement quoted above, and which might mislead persons unacquainted with the peculiarities of the two methods.

The other error consists in ascribing to water from Ulleswater and the Thames at Kew an equal quantity of chlorine, represented by the figures 0·7 to 0·8 grains per gallon—a mark of quality that Thames water certainly does not come up to. The chlorine in the Thames at Thames Ditton averages 1·2 grains per gallon, and it is hardly likely to decrease in quantity after receiving the refuse of other places between Thames Ditton and Kew.

From a careful examination of this first volume, we should certainly place Messrs. Roscoe and Schorlemmer's work in the very highest rank among chemical text-books. If the succeeding volumes are only equally thorough, we know of no English manual which can be placed on a par with it.

(*a*) A second volume, as we last week notified, is announced as being nearly ready for publication.

(*b*) Had the very ingenious invention, "Ansell's Fire-Damp Indicator," been adopted by mine owners In 1866, when it was first offered to the public, the lives of thousands of human beings might have been saved to the country.

Hysterotomy in Dublin.

Dr. Thornley Stoker, of the Richmond Hospital, Dublin, performed the operation of removing the uterus on Thursday last, for an enormous myoma engaging almost its entire substance. The patient was twenty-six years of age, had borne a child, and suffered from the disease for two years. Extensive adhesions existed and presented much difficulty, the cervix uteri being ligatured and secured as a pedicle in the wound. By latest accounts the patient is doing as well as possible.

The Vice-President of the Irish College of Surgeons.

It is usual for those who seek the honour of the Vice-chair of the College to announce their candidature a year in advance. In compliance with this habit, Dr. A. H. M'Clintock, formerly Master of the Rotundo Hospital, and Dr. Chaplin, Surgeon to the Kildare co. Infirmary, have announced that they will present themselves for the office in June, 1879.

Medical News.

St. Thomas's Hospital.—The annual distribution of prizes to students in the College attached to this Hospital took place on Friday by Mr. Le Gros Clark, F.R.S., Hon. Consulting Surgeon to the Hospital. The following is the list of principal prize-takers:—Prizes for Summer Session, 1877—*First Years' Students:* W. A. Duncan, R. Heelis, and F. W. Nicholson each received the College prize and certificate of honour. *Second Year's Student's:* A. Newsholme, T. D. Savill, and Takaki Kanehiro each received the College prize and certificate of honour. Prizes for Winter Session, 1877-78.—

Entrance Science Scholarships: W. Wansbrough Jones, scholarship £60; A. E. Wells, scholarship £40. *First Year's Students:* W. Wansbrough Jones, the Wm. Tite scholarship £30; F. W. Stoddart, College prize £20; M. Jay, Wallaroo, College prize £10. *Second Year's Students:* W. A. Duncan, Manchester, Musgrove scholarship 40gs.; H. N. Holberton, Middlesex, College prize £20. *Third Year's Students:* A. Newsholme, College scholarship 40 gs.; A. Newsholme, College prize £20; Takaki Kanehiro, College prize £15. *Solly Medal and Prize*—C. E. Sheppard. *The Cheselden Medal in Surgery and Surgical Anatomy*—W. F. Haslam. *The Mead Medal in Practical Medicine*—S. J. Taylor, Grantham. *The Treasurer's Gold Medal for General Proficiency and Good Conduct*—S. J. Taylor.

The Metrical System amongst the Assyrians.

THE *Am. Journ. Pharm.* states that from the library of Sardanapalus, king of Assyria (found by Layard at Nineveh), it is proved that the Assyrians, some three thousand years ago, had a system of weights and measures almost as philosophical and methodical as the French metrical system, all the units of surface, volume, and weight being derived from a single linear unit. The base of the system was the cubit or elbow (equal to 20·67 of our inches). These cubits, multiplied with three hundred and sixty, gave the stadium measure for great distances. The fundamental unit of surface was the square foot (foot equal to three-fifths of the cubit). The cubic foot constituted the metreta (bushel), which, with its subdivisions, was the standard of all measures of capacity. A metreta of water was the talent, the unit of all measures of weight. The sixtieth part of the metreta gave the mine, and this, divided into sixty parts, the drachm. The weight of the metreta (or bushel, water) was about seventy avoirdupois pounds, the mine about 18·7 ounces, and the drachm about one-hundred and fifty-nine grains. The sexagesimal system appears to have been used in all these calculations, and is evidently a very practical one, combining the advantages of the decimal and the duodecimal systems.

Cadaver Alkaloids.

IN the course of toxicological researches, Prof. Selmi, of Bologna, recently found in extracts from the bodies of persons that had died naturally, several substances having the general characters of alkaloids. He supposed that these substances, which he calls *ptomaines* (πτωμα a corpse), arise from spontaneous decomposition of cadaveric matter, and this was fully confirmed. He was led to study the properties and mode of formation of these alkaloids, and the reactions which distinguish them from vegetable alkaloids. The grave consequences which may flow from a mistake in a medico-legal investigation, lend a special interest to Prof. Selmi's researches. A full account of them will be found in the *Moniteur Scientifique*, for May.

THE use of horseflesh is being slowly but surely developed at Marseilles. Thus, whilst there was only a consumption of 1,031 horses in 1875, it amounted in the following year to 1,068, and in 1877 to 1,142.

NOTICES TO CORRESPONDENTS.

☞ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

READING CASES.—Cloth board cases, gilt-lettered, containing 26 strings for holding each volume of the MEDICAL PRESS AND CIRCULAR, can now be had at either office of this Journal, price 2s. 6d. The postal regulations not allowing the Journal to be stitched, these cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

NOTICE TO SUBSCRIBERS.—Subscribers who have not already paid their subscriptions for last year are reminded that they are now due and should be sent to the publishers, who will be happy to acknowledge their receipt.

R. RUDING, Secretary, the London and General Water Purifying Company, Limited.—Your letter received as we were going to press; it will be inserted in our next.

VALE.—Your communication received too late for insertion in our present issue.

CONSTABULARY ATTENDANCE AND REMUNERATION.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—I shall feel obliged if you can inform me whether a doctor in charge of police in his district is bound to attend not only the men but also their wives and children on the same remuneration as allowed by the R.I.C. regulations? For instance, if a man of the force, or any number of them, happen to be absent at a certain time the doctor of the district is minus the allowance, while, during his or their absence, the wife or children *may* require his aid, and for the latter is he not entitled to his fee?

Yours, &c.,
M. G.

[According to the Regulations ("Irish Medical Directory" for 1878, page 321) the medical attendant is bound "to attend the wives and families of men stationed in the district." The number of men to be paid for, each month, is to be the average number present during the month, to be ascertained by adding together the number present in his district on the morning of each Saturday in the month and dividing the total by the number of Saturdays. It would seem from these Regulations that if a man should be temporarily absent for any period less than a week he is, nevertheless, held to be "stationed in the district," is counted in the allowance, and entitled to the attendance of the medical man for his wife and family. If the man be absent for two consecutive Saturdays he is plainly not "stationed in the district," and his family would have no right to attendance; but we assume that the medical attendant would not decline to look after them unless the man was known to have permanently left the locality.—ED. M. P. & C.]

VACANCIES.

Kenmare Union, Kenmare Dispensary.—Medical Officer. Salary, £100. Election, June 26.

Limerick Union Workhouse.—Apothecary. Salary, £100, with apartments and allowances. Election, June 19.

Royal Bethlem Hospital for Lunatics.—Assistant Medical Officer. Salary, £300, with furnished residence. Printed forms of application can be obtained of Mr. Jeaffreson, at the Hospital. (See Advt.)

Southam Union, Warwickshire.—Medical Officer. Salary, £45 per annum, fees extra. Applications to the Clerk to the Guardians.

Westmoreland Lock Hospital, Dublin.—Resident Apothecary and Accoucheur. Salary, £75, with apartments and allowances. Election, June 14.

Wilts County Lunatic Asylum.—Assistant Medical Officer. Salary, £110, with board, residence, &c. Applicants must be unmarried, and should address the Clerk to the Committee, Devizes.

Wolverhampton General Hospital.—House Surgeon. Salary, £100, with board. Applications to Mr. Vincent Jackson, at the Hospital.

Births.

BOURKE.—June 1, at 3 Great Denmark Street, Dublin, the wife of Martin E. Bourke, Surgeon, R.N., of a daughter.

LYSTER.—At Kilkenny, the wife of C. G. Lyster, F.R.C.S.I., of a daughter.

Marriages.

MACDONNELL—BURD.—June 1, at St. Mary's Disley, Cheshire, Hercules Henry MacDonnell, M.D., to Fanny Keogh Burd, daughter of John Burd, Esq.

WALSH—HALL.—June 1, at Limerick, Thos. Burke Walsh, L.R.C.S.E., of Ballyclough, Mallow, to Maria Louisa, eldest daughter of Ambrose Hall, Esq., J.P.

Deaths.

CROWLEY.—On May 21, at Bandon, co. Cork, Patrick Crowley, L.F.P.S.G., aged 42.

GROVES.—On May 29, at Upway, Dorsetshire, Matthias Groves, M.R.C.S.E., aged 32.

HUNTER.—On May 20, at Kilbirnie, Ayrshire, William Hunter, L.F.P.S.G., aged 53.

JAMISON.—On June 4, at Dungannon, co. Tyrone, George Jamison, M.D., aged 65.

KEALY.—On June 5, at Drogheda, co. Louth, John L. Kealy, M.D.

PARKS.—On June 3, at Bankfield, Ainsworth, James Parks, M.R.C.S., late of Bury, aged 65.

PENTLAND.—On May 31, at Queensboro', Drogheda, Henry Pentland, M.D., of Kells, co. Meath, aged 75.

WALKER.—On May 31, at Chesterfield, Hugh Eccles Walker, M.D., F.R.C.S., aged 62.

IRISH POOR-LAW INTELLIGENCE.

IRISH MEDICAL ASSOCIATION.

ANNUAL GENERAL MEETING,

Held at the ROYAL COLLEGE OF SURGEONS IN IRELAND *on* MONDAY, THE 3RD JUNE, 1878.

DR. A. O'KELLEY NOLAND (Gort.), Vice President for Connaught, in the chair.

REPORT OF COUNCIL FOR THE YEAR ENDING 31ST MAY, 1878.

MR. CHAIRMAN AND GENTLEMEN.—Your Council held four ordinary (and one special) meetings during the past year; and the Committee of Council (upon whom most of the business devolves) held forty-seven meetings.

The Public Health (Ireland) Bill.

The Public Health (Ireland) Bill of last year is still before Parliament. The Council are glad to report that, in consequence of the action taken under their direction, considerable and important modifications have been made in this Bill, all of which are favourable to the interests of the Medical Profession; the proceedings relative to this measure which have taken place since the last Annual General Meeting are as follow:—

On July 17th, Sir Michael Beach gave notice of his intention to have the Bill referred to a Select Committee of the House of Commons, and this proposal was carried into effec, a few days later. The Select Committee was appointed and met for the first time on July 23rd. In anticipation of this event, and acting under the advice of several parliamentary friends, your Council requested their Chairman to proceed to London with the view of watching the progress of the Bill on behalf of this Association; and having had their Observations on the Public Health Acts, and on the new Bill, revised and reprinted, a copy was sent to each member of the Select Committee, together with a letter and a copy of the report of the proceedings of the deputation which waited on the Chief Secretary in London on the 17th May, 1877; a special letter was addressed to the Chairman requesting that he would submit the Observations of the Council to the Select Committee, and asking if that Committee would receive such evidence as the Council were anxious to tender on behalf of the Profession, to which a reply in the negative was received; whereupon a further letter was addressed to the Chairman of the Select Committee, reminding him of the observations he made to the deputation on the 17th May, and informing him that the Chairman of Council was in London, and had been authorised to act on behalf of this Association. Although the Select Committee did not receive evidence, the views of this Association were fully brought under their notice by Mr. Meldon and Sir Arthur Guinness, the former specially undertaking to propose and support those amendments which immediately affected the interests of the Profession.

It will be remembered that the amendments proposed by the Council had the following objects, viz.:—

1st—To secure the title of "Medical Officer of Health" for the Dispensary Medical Officer.

2nd—To remove the objectionable provision by which a *maximal scale* of remuneration was fixed for their services under the Act.

3rd—To secure a definite and adequate fee for sanitary services on board ship.

4th—To secure remuneration for attendence at sanitary prosecutions.

5th—To secure an adequate fee for certifying for the removal of a dead body of a contagious disease.

6th—To secure constant and independent supervision by competent professional inspectors directly under the control of the Local Government Board.

The first of these proposals was carried by an amendment by which the position of the Dispensary Medical Officer is defined as "Medical Officer of Health," thus distinguishing him from all other sanitary officers.

The second point (the fixed maximal scale) was not carried before the Select Committee, but the Chief Secretary accepted an amendment subsequently proposed to the House of Commons by Mr. Meldon, which, if adopted by the Chief Secretary, will produce the desired result.

The third point (remuneration for services on board ship) has been secured by an amendment by which the fee is to be fixed by the Local Government Board, and as the Board has never fixed a lower fee than one guinea for such services where it had the power of regulating the amount, your Council expect that this point will be fairly dealt with.

The fourth point (remuneration for attendance at prosecutions) was carried before the Select Committee by a new clause drafted by the Chairman of your Council, which gives the Local Government Board power to regulate the fee. As it may be expected that the same scale of fees which is now in force by order of the Attorney-General for remuneration of medical witnesses at Sessions' Courts will be adopted by the Local Government Board, your Council consider this question also will be fairly settled.

Your Council regret that the fifth point (certifying for removal of dead bodies), owing to an accident, was never raised before the Select Committee; but it is said to be hoped that the objectionable ten shillings fee will be modified when the Bill again comes before the House.

The sixth point (supervision) still remains an open question. It was brought before the Select Committee, but as the Government already possesses the power of carrying out the proposal, the question must be settled by influencing the opinion of the Executive. This, there can be little doubt, has already been done by this Association, and it is now generally admitted that *independent supervision is necessary*; and your Council having good reason to believe that the Government has recognised this necessity, hope that it will provide efficient supervision in future.

It will thus be seen that nearly all the legislative points advocated by this Association, and by the Dispensary Medical Officers, in their petition, have been conceded by the Government, and that the proposition for efficient supervision has been favourably entertained. Under these circumstances, their Chairman, acting under the instructions of your Council, consented, on behalf of this Associations. to withdraw all further opposition to the Bill, which would

doubtless have passed but for opposition raised on political grounds, with which your Council were powerless to cope. Sir Michael Hicks Beach, when withdrawing the Bill, expressed a hope that "what had been done that Session would not be lost, but would assist the passing of the Bill next Session;" he also stated to the Chairman of your Council that he would give his support in the House to all the amendments which had been, at the suggestion of this Association, inserted by the Select Committee, as well as those subsequently agreed to.

Your Council have great pleasure in reporting that by his advice, their Chairman was able to render valuable service in improving the Bill in many ways, which, although not affecting the position or emoluments of the medical profession, have made the Bill a much more perfect measure than it otherwise would have been, and also have proved to the Government and the public that this Association is always willing to give its best aid in promoting measures for the improvement of the public health, although such improvement may not either directly or indirectly benefit the profession.

Upon the return of their Chairman to Dublin, your Council, in acknowledgment of the valuable services rendered by him, as well as of the success of his mission (notwithstanding his many great difficulties), accorded him an unanimous vote of thanks; and also unanimously adopted a resolution expressing the gratitude of this Association to Mr. Meldon, M.P., for his valuable advice and support.

(To be Continued.

THE following is the continuation of the correspondence with the Commissioners of Metropolitan Police respecting the duties of the police to give information to the coroner as to the medical attendant of the deceased person on whom an inquest is held.

Metropolitan Police Office,
Dublin Castle,
7th March, 1878.

SIR,—I am directed by the Chief Commissioner of Police to acknowledge the receipt of your further communication of 5th inst., and to state that the 22nd section of the Act 9 and 10 Vict., cap. 37, does not contain any reference to Medical Evidence. The words are, that the Police shall give "notice thereof (finding of a dead body) to the Coroner of such district, together with such information as he or they (the Police) shall have been able to obtain, touching the finding of such dead body or such death." The section further provides that the Coroner (not the Police) "shall issue a summons for every witness whom he shall deem necessary to attend such Inquest;" and under the 33rd section the duty of summoning some Medical Practitioner, as witness, is vested altogether in the Coroner. The 34th section gives power to the Coroner, on the requisition of the Jury, to summon some other legally qualified practitioner or practitioners by way of further evidence.

As the law, as will be obvious from the foregoing references, solely and wholly contemplates the Coroner as the only person legally qualified to summon Medical Practitioners as witnesses, the Commissioner begs you will be so good as to state whether the Irish Medical Association have brought under the notice of the Coroner for the City of Dublin the decision referred to in your letter of 21st ult. that the present "practice is illegal and contrary to the policy of the law, as defined by the 33rd section."

I am, Sir,
Your obedient servant,
J. A. CONOLLY,
Assistant Commissioner.

Irish Medical Association,
Royal College of Surgeons,
16th March, 1878.

To Colonel Conolly, V.C.,
Assistant Commissioner,
Dublin Metropolitan Police.

SIR,—I am directed by the Council of the Irish Medical Association to acknowledge the receipt of your letter of the 7th inst., and to state that the reference in my former letters to the 22nd section of the 9th and 10th Vic., cap. 37, was made *solely for the purpose of pointing out the duties of the Police with regard to the "information touching a death," which they are thereby required to give to the Coroner;* no statement was made in any of my letters which bore the inference that *that* section contained reference to *Medical Evidence* at Inquests, and it would not have been called in question but for the statement contained in your letter of the 13th February—that the Commissioner of Police "regrets to say he is not in a position to take any step, as the law gives the Police no discretion in the matter;" the Council having been advised that it was obligatory on the part of the Police to give to the Coroner the information indicated in my former communications.

In the trial of the case, viz., "The Queen at the prosecution of Jacob *v.* Finlay," already referred to, the Coroner for Dublin City pleaded in defence, that *in every instance* in which he had been informed that a Medical Practitioner was in attendance, at or about the time of death, he summoned such Medical Practitioner and examined him at the Inquest; but as only *nine* Medical Practitioners, other than the Coroner's standing Medical Witness, were called on to give evidence out of a total of 263 Inquests held, it must be apparent that the Coroner *did not receive from the Police all the information* which they might and should have been able to obtain, in compliance with the 22nd section.

The Council are thoroughly aware that it is the duty of the Coroner, *not of the Police*, to issue summonses for the necessary witnesses; and that it is his duty to summon, as Medical Witness, a Medical Practitioner, *whose special qualifications to act as such* are defined by the 33rd section. The Council are also thoroughly aware of the powers vested in the Coroner and the Jury by the 34th section.

In reply to the question contained in your letter of the 7th inst., the Council have instructed me to state that, by order of the Court of Queen's Bench, the Coroner for the City of Dublin was served with notices similar to those served on Mr. Finlay; that the Coroner not only filed affidavits, but also appeared by Council as a defendant in the suit, and had to pay his own costs; but the Council cannot see that any omission on the part of the Coroner to comply with the law, can relieve the Police of the responsibility devolving on them under the 22nd section.

I am, Sir,
Your obedient servant,
JOHN H. CHAPMAN, Hon. Sec.
60 Pembroke Road, Dublin.

Metropolitan Police Office,
Dublin Castle,
22nd March, 1878.

SIR,—I am directed by the Chief Commissioner of Police to acknowledge the receipt of your further letter, bearing date the 16th inst.

In reply, the Commissioner has only to say that every legitimate duty devolving on the Police, under the Act in question, will be carried out by them.

I am, Sir,
Your obedient Servant,
J. A. CONOLLY,
Assistant Commissioner.

The Committee of Council are informed that the Instructions promised to be issued by the Inspector-General of Royal Irish Constabulary, in compliance with the suggestion made by the Council, have already been issued to the Constabulary.

The Committee of Council having requested the attention of Mr. Lloyd, Solicitor to the Association, to the audit of the accounts of the Corporation of Dublin, now taking place, a notice approved of by the counsel who represented this Association in the recent trial of the

case "The Queen at the prosecution of Jacob *v.* Finlay," was served upon the Auditor with a view to enforce the judgment of the Court of Queen's Bench in Ireland concerning the employment of Medical Witnesses at inquests, whose special qualifications to act as such are defined by the 33rd section of "The Coroners' (Ireland) Act" (9 & 10 Vic., cap. 37), and the Auditor has promised to give Mr. Lloyd due notice of the time he will enter into the investigation of payments to the Coroners' Medical Witnesses.

Abuse of Dispensary Medical Relief.

It will be remembered that, in March, 1877, a circular was forwarded to each dispensary medical officer in Ireland, putting some queries, and submitting some suggestions which were made with a view to check this defect. Over 300 dispensary medical officers responded; and Dr. Speedy kindly undertook the laborious task of examining and tabulating the replies, and he submitted a very carefully prepared and lengthy report on the subject to the committee of Council, who are of opinion that a favourable opportunity now offers of bringing this very important subject under the notice of the Legislature, and the various authorities, by communicating with the Poor-law Union Inquiry Commissioners, now collecting evidence with regard to Poor-law matters; and with this view the committee of Council have drafted a letter [we have referred fully to the letter already], which they believe embodies the views of the vast majority of the profession, at least of those who replied to the circular referred to, which they recommend to be sent to these Commissioners.

Examination of Alleged Dangerous Lunatics.

The committee of Council having very frequently received complaints from dispensary medical officers, who were not paid for examining alleged dangerous lunatics, ascertained that, in a great measure, the refusals were due to the fact that no form of application for such fees was in use; they accordingly drew up a form in compliance with the terms of the 14th section of the Lunacy (Ireland) Amendment Act (38 & 39 Vic., cap. 67), and have had it printed. A few copies of this form shall be sent to each dispensary medical officer who is a member of this Association, and further copies can be obtained on application to the hon. secretary. Whenever a dispensary medical officer is *called in by order of the Justices* to examine an alleged dangerous lunatic, he should fill in the required particulars in the form and present it to the Justices for signature, and when he receives it, so signed, he should at once forward it to the guardians of the Union for payment; it should, however, be observed that the Justices are not empowered to order payment of a fee for examination of an alleged dangerous lunatic *unless the examination has been made by their order.* It is not necessary that the alleged dangerous lunatic should be certified to be a dangerous lunatic, or even merely a lunatic, to entitle the medical officer to a fee, as the fee is allowed for the *examination;* and it should also be borne in mind that the Justices have power to refuse, if they see fit to do so, to certify for the payment of any fee for such examination.

The following is the form of certificate referred to, and the committee of Council propose to supply forms of a like nature for all similar purposes.

38th and 39th Vic. cap. 67.

"Lunacy (Ireland) Amendment Act."

Whereas, on the day of 18 , one was charged before us as being a Dangerous Lunatic; and whereas we caused the said to be examined by Dr. the dispensary medical officer employed as directed by the Act; we hereby, in pursuance of the powers vested in us, make an order on the guardians of the Union, to which said belongs, for the payment of as reasonable remuneration to the said medical officer, as provided by the 14th section of the above Act.

Signed,

_____ } Justices
_____ } of the
_____ } Peace.

day of 187 .

Examination af Harmless Lunatics.

The committee of Council having observed that a Commision has been appointed by Parliament to inquire into the arrrangements relating to lunatics in Ireland, addressed a letter to the Commissioners, which has already appeared in the columns of the MEDICAL PRESS.

(To be continued.)

THE WORKING OF THE PUBLIC HEALTH ACT.

THE annexed correspondence, comprising the letter from the Local Government Board and the report of Dr. Moore, the sanitary officer, addressed to the guardians of the Ardee Union, reveals a sad state of matters in the Ardee district.

"The Local Government Board for Ireland acknowledge the receipt of the minutes of the board of guardians of the Ardee Union of the 30th ult. . . . . The Local Government Board regard default in sanitary matters in the same light as default in the execution of duties under the Poor-law Act. The Local Government Board request that the guardians will be good enough to have the defects in the pumps and their surrounding which the sanitary officer has pointed out, remedied without further delay, and that they will call on that officer to furnish a report in the proper form as to each nuisance which he may consider dangerous to health, stating at the same time his opinion as to the best means of abating such nuisance, and of preventing its recurrence. The clerk of the union should enter each of the sanitary officer's reports in the minutes, with the order made by the guardians in each case.

"B. BANKS."

The following is Dr. Moore's report:—

"In compliance with your application I have to state in reply, speaking generally of the entire district, there are no sanitary arrangements carried out, and if I except the exclusion of pigs from the dwellings, which is not pretty general, the same state of things remains as before the Sanitary Act came into operation. Cess-pools and manure heaps close to the cabin door are still as common as ever. Even with houses provided with reres, fowls are universally housed with the family, and occasionally the pig, goat, and donkey. Many houses, even in the country, are totally unprovided with reres, while others which have been reported as uninhabitable are still in the same state, and occupied. So much for the district in general. Now for the town of Ardee, the chief centre of population in my district. The lanes are, as a rule, kept in a most filthy condition; the main street is kept clean, and is healthy in dry weather, or when heavy rains have flushed the water-tables, but in sultry weather the condition of these water-tables is most offensive. This nuisance is caused by the vicious practice which prevails in this street of running a narrow gullet from the rere to the water-table in front, which not only contaminates the air of the dwelling under which it passes, but frequently discharges most offensive matter on the public street. An objectionable manure-heap and filthy pig-sty at the rere of many houses, feed these small drains. The extent of these abominations may be estimated by the amount which is barrowed through dwellings (!) into the public street for sale at this season of the year. The pumps erected by the Town Commissioners and Board of Guardians are in general (not all) in working order, but as rule no provision has been made around those pumps to carry off the waste water."

The state of affairs here depicted is that which exists in

most Irish towns. It happens to come under the notice of the Local Government Board because it is forced upon their consideration by the medical officer. They have no inspection to enable them to know anything about it, and they set their face against providing any such inspection.

MOUNTMELICK UNION.

DR. WILKINSON'S SUPERANNUATION.

Mr. Phillips in proceeding with his notice of motion regarding the above, regretted that it had not fallen into better hands. He observed that Dr. Wilkinson had fulfilled all the requirements of the Act relating to superannuation, and that he was perfectly eligible for it. He was upwards of seventy years of age; he had spent twenty-six years in the service of the board, well and faithfully, and he was now in a poor state of health. When this matter was discussed on a former occasion, it was argued that in determining the superannuation they would give, Dr. Wilkinson's emoluments should not be taken into account; but the Act 35 and 36 Vic. cap. 89, provided for that difficulty, and said "The emoluments of his office on the average of three years may be taken into calculation by the guardians." This set all doubts on the matter aside. Dr. Wilkinson's superannuation was based on the average for the years 1875, '76, and '77. His salary and emoluments for the three years made up a total of £387 5s. 2d. or £129 1s. 8d. per year; and the two-thirds of that, which it was now proposed to give him, was £86 1s. 1d.

Mr. Reeves seconded the motion. He remarked that Dr. Wilkinson was an old man who had grown grey in their service, and whose feet, he might say, were now in the grave. He had lived in a very poor district, where there were little opportunities for private practice. It would be useless for him to take up the time of the board in saying anything more, as a great many guardians came there pre-determined to vote one way or the other; but if they wished to have a good set of officers in the union they should show those who served them faithfully that they would give an adequate reward.

Mr. W. H. Cobbe followed. He designated the superannuation allowance all through his observations as outdoor relief (to which several guardians took exception), and urged that they had fulfilled their contract with Dr. Wilkinson, who until within the last few years could not have expected superannuation, because the Act was only passed in 1874.

Mr. Cullen moved the following amendment:—

"That the medical officers having gladly accepted their situations at three-fifths of their present salary, without any expectation of superannuation, it is an act of injustice to appropriate any portion of the rates to their superannuation."

Mr. T. Cobbe's amendment for £52 was then put, with the following result:—For, 16; against, 24.

Dr. Rice applied for a fee of £2 for assisting in a midwifery case. The order for his attendance came through the medical officer, who required his assistance, the relieving-officer having given the necessary order to the latter.

On a division, a majority of 16 to 10 voted for the £2, whereupon Mr. Cobbe handed in a motion calling the attention of the Local Government Board to the matter on the grounds that Dr. Rice was not employed directly by the relieving officer.

ON HEADACHE.

A Lecture delivered in Gresham College on May 10th, 1878.

By E. SYMES THOMPSON, M.D., F.R.C.P.,
Gresham Professor of Physic, &c.

THE Founder of our College desired that the Professors should deliver addresses of practical utility to the citizens of London, and it is my wish to carry out the intention of Sir Thomas Gresham, and to give to any here who suffer from headache, or have around them those who do so, such suggestions as may be of service in relieving pain and preventing the establishment of what might otherwise prove a life-long misery.

Headache is merely the name of a symptom which may occur in a multitude of disorders. It is often met with in the course of jaundice or kidney disease, and is then regarded as part and parcel of the deeper underlying ailment. The term, however, is employed mainly to describe those conditions in which head-pain is the pronounced and manifest evil.

The better to understand the nature and varieties of headache, some description of the parts involved is needed. This anatomical description must be of the most general kind.

Beginning from the outside, there is first the hair, next the scalp, which covers the bone, next the bone covered by periosteum, and next the brain covered in its turn by the dura mater, a fibrous tunic which embraces and keeps it together, and sends partitions between the hemispheres and between the larger (cerebrum) and smaller (cerebellum) brain. The dura mater supports the vessels which convey blood to and from the brain.

This rapid survey sufficiently indicates that, as the parts affected are various, so the painful sensations to which these parts are subject may be various in kind, in degree, and in results.

Headache, like any other pain, is given as a warning, not to be slighted but to be attended to, and very often it is the earliest evidence of removable mischief, which, if neglected, passess into hopeless disorganisation.

The scalp may become tender and painful from hard brushing, parting the hair in an unusual place, or hanging on to it a weighty superstructure.

Those who have too much hair or wear it too long have headache sometimes in consequence, and persons leading a sedentary life with excess of food and wine, find the tonsure promote coolness of head and freedom from oppression. The malady as it affects gouty subjects is often accompanied by heat of head, and it is a good thing for gouty old gentlemen that they are often bald. *Gouty* headache is accompanied by fulness, flushing of the vessels, and if neglected may lead to giddiness and apoplexy.

Rheumatic Headache attacks those who are not comfortably housed and well supplied with warming food; it favours persons living in damp low-lying situations or exposed to raw winds when imperfectly clothed; it fixes itself in one part of the aponeurosis between the scalp and skull; and notwithstanding warmth, anodyne embrocations, and alkaline draughts, it is very apt to remain for several days, and only yields to iodide of potassium and sarsaparilla.

This differs from *neuralgic headache* which occurs in plunging paroxysms like tooth-ache. Often it depends on a bad tooth and is removed with it, or it is intermittent and dependent on ague or marsh poison, in which case it may be cured by a good dose of quinine. Sometimes intense neuralgic headache depends on a swelling on the nerve as it passes a foramen or hole in the skull, and then mercury or iodide of potassium must be relied upon.

Nervous Headache, as it is called, is not like *Neuralgia*. To depict a case: here is a pale, thin woman, with bright eyes and an anxious over-wrought expression, who tells us she is a martyr to it; sometimes she is free for weeks, but when she is "put about" or worried, the head is almost constantly aching, unfitting her for work and making life a burden. It cannot, she tells us, be due to

over-eating, for she takes little besides tea and toast, she never takes any breakfast, and the pain is worse in the morning. The pain is, indeed, "the prayer of the nerve for healthy blood." On inquiring the cause, we find that it began first years ago, when her nights were disturbed by a sick child and by her husband's misfortunes.

Cases of this kind are common among seamstresses and underpaid washerwomen, but they are not rare in the higher walks of life, for the ladies who look so graceful and prosperous in their luxurious carriages are often harassed by anxieties we know not of, and tormented by carking cares to which the poor are strangers. These are cases in which valerianite of zinc is useful; the attack may be lessened by *guarana*, the new popular tea-like drug; but to supply the worn nerve with good blood is the real point, and food containing fat is essential, as milk and cod-liver oil, and let bread and milk take the place of tea. Although wine or spirit *taken with food* may be of real temporary benefit, it is the doctor's duty in cases like this to discourage the use of alcohol, for soon a craving for it will be developed, which, from weakened powers of resistance, the patient will be unable to escape.

The very opposite conditions to those just described give rise often to headache. I mean not defective or lacking nourishment but over-eating. Bad cooking or imperfect mastication *may* be the cause, but generally eating too fast or eating too much is the evil. Some may remember my allusion in this Hall years ago to the evil of *Luncheon Bars*. The observations were quoted in some of the commercial papers of this city, and I hope have been taken to heart by some; there can be no question that many become dyspeptic and get headache because they allow themselves but a few (five or ten) minutes to "bolt" (no other term is appropriate) a plate of meat, with beer and perhaps cheese and salad, and are at their desk and bustling work without a moment's interval for the stomach to attack the food while the brain is untaxed. If the time is very short it is better to take a light meal than to "bolt" a heavy one.

In this dyspeptic form of headache the feet get cold, the head hot, and face flushed; soon a dull heavy pain comes with throbbing at the temples. The tongue becomes coated, mouth clammy, breath offensive. The pain shifts about, and is increased in the upright posture. The patient declares, perhaps, that the headache cannot be due to indiscretion in diet, for he had a specially light, wholesome meal the previous day; on inquiry, it will be found to be due to an error two or three days before, or most probably a wrong plan long followed.

Headache from over-eating in children, may be relieved by an emetic. Growing children *must* have their digestion in order, or they will be stunted in growth, and imperfect in development.

Headache from over-drinking, comes on the morning after the "bout," and may be unaccompanied by any sign of disorder of digestion, for the patient endurance of the stomach is almost beyond conception. It is relieved by brandy and soda, or better by soda water, or even by cold water alone.

Let me now bring before you a typical case of plethoric or congestive headache.

Here is a burly, fresh-coloured gentleman, who looks the "picture of good nature," and whose face certainly does not pity him; but if you look at him attentively, you see the red cheeks are due to tortuous vessels and stagnant circulation. His lips, too, are blueish, and the nose red. When he stoops he flushes deeply. He complains of noises in the ears, and pain in the bridge of the nose; and he gets so sleepy after meals that he *must* have his nap. His habits are sedentary, and he becomes less and less disposed for walking. He has, perhaps, lately retired from business, having made his fortune. He considers his diet spare, as he seldom eats meat more than three times a day, and rarely takes anything between lunch and dinner, and he is "doing Banting" to the extent of taking a biscuit with his cheese and port. Two or three times he has had nose bleeding. This may probably have saved him from apoplexy, and till he gives up his port, and two of the three heavy meat meals, and leads an active life, he will suffer from his headache, and perhaps some morning will have an apoplectic seizure and never regain consciousness.

Time will not allow me to speak of the headache of hysteria or hypochondriacs.

Sick Headache is primarily due to nerve wear, but being treated by anti-dyspeptic remedies, it becomes accompanied by, and eventually chiefly caused by, stomach disorder. It is apt to attack those who inherit a predisposition to affection of the brain. The grandmother of the patient was perhaps epileptic, father subject to tic, one brother consumptive, and another insane. It is periodic in its onset, necessitates complete recumbency and withdrawal from noise, glare, and bustle. The sickness is the consequence, and not the cause of, the headache, just as sea-sickness is dependent on disturbed circulation in the brain, secondarily affecting the stomach. In treatment, many things, *e.g.*, sal. ammoniac, mindererus, coffee, or chloral, give relief, but our sheet anchor is a prolonged course of iodide of potassium.

The headaches of children require special care and discrimination; those of measles and scarlet fever soon pass away on the appearance of the rash. They are at times as severe as is the characteristic backache of small-pox.

School-boys and students sometimes get a severe form of headache from overwork, which needs vigorous and decisive handling, or it is followed by organic disease. Several distressing cases of this kind have fallen under my care. In such cases cessation from head work is the first essential. Country life or a sea voyage are the remedies. These are cases in which the brain tissue is deteriorated and softened either from strumous disease, or overstrain of feeble brain. In fevers the consistence of the brain is reduced, so that its specific gravity is less than it should be. In insanity it is harder and heavier, the fluids around being increased. The proportion of phosphates, too, varies considerably; hence the suggestion that phosphorus is the remedy in such cases.

Disease of brain is sometimes painless, for the brain substance has no sensitive nerves, and in hernia cerebri you can touch the brain without the knowledge of the patient; but if you press firmly on it, uneasiness or convulsion occurs.

If the membranes covering the brain are affected, there is sure to be pain, generally of an abiding kind, and in a fixed spot. In such a case the pain is increased by engaging the patient in conversation, instead of being diminished, as is usual in other forms of headache.

A large abscess may destroy a hemisphere without symptoms, as in a case once under my care, but a small tumour on the surface may give rise to acute pain, and perhaps paralysis. Tumours are of many kinds, fibrous, cystic, aneurismal, or cancerous. This is a subject for a lecture in itself. I can only allude to it here. Tumours often cause epilepsy, as well as headache. If the tumour is aneurismal, it may burst into the brain, with an immediately fatal result.

The treatment of epilepsy has of late greatly improved, and at least, partial benefit may now be counted upon. Typical sick headaches are, as I have said, allied to epilepsy. They are commoner now in these days of high-pressure and competition than formerly, for disorders of the nervous system have taken the place of the disorders of the circulation which so frequently affected our easy-going free-living ancestors.

A few words now about treatment. First *preventive treatment*. Had this been more successful in times past many valuable lives might have been saved.

Isaac Newton always found that when he worked at the theory of lunar irregularities it made his head ache, but it never ached when studying any other subject. He neglected the warning, and after resuming his intense application to this abstruse subject, the severe illness which ultimately cost him his life, commenced; and thus the world lost with Newton the power of mastering other

phenomena as important perhaps as that of gravitation.

The value of one such life who shall estimate!

Congestion of brain, when habitual, leads to feeble memory, dimmed intellect, weak sight, or perhaps even to blindness and deafness; a cautious bleeding (old-fashioned remedy though it be) may prove the best treatment in such a case.

Symptoms ought to be *early* attended to; work must not be too prolonged or intense, nor must the intervals between meals be too long, or the quantity taken unsuitable to the habits and requirements of the body. Hard mental work cannot be done without good sustaining food, any more than an engine can work without fuel. Let the diet be regulated; let the clothing be ample but not excessive; let the digestion be kept in order, the exercise be appropriate, the rooms airy.

These are general principles applicable to all. But remember that headache is a symptom. Its cause must be discovered and obviated.

When ascertained, if found to be dependent on rheumatism, a great effort should be made to secure a dry comfortable house, on a gravelly or sandy soil. Flannel should be worn near or next the skin, vigorous friction after the morning bath, a diet nutritious but not such as to develop acidity, for many forms of rheumatic headache are promoted by sugar, by porter, and sweet wines.

I need not repeat what I said about the character of rheumatic headache, that it is superficial, accompanied by tenderness increased on moving the scalp; nor need I allude further to its causes or the treatment, which is that of rheumatism generally.

The *congestive* or *plethoric* headache may be known by the sense of fulness and weight in the head, with occasional giddiness. The pain is throbbing, it comes and goes, it may be produced by stooping, sleeping with the head low, wearing a tight necktie (or "choker," as it may more appropriately be called), or even by tight stays. This form of headache is not confined to those who indulge in good living, but it affects those, too, who are pallid and bloodless, for persons with too little blood are even more prone to congestion than those with too much. You will all see how essential a sound diagnosis must be under such circumstances, for what may cure the full-blooded, will certainly greatly injure those whose blood-supply is deficient. These cases may be benefited by derivation, *i.e.*, attracting blood to other parts, as by warm baths, or mustard plasters, by cupping, or by vigorous friction. Suitable drugs are too manifold to name.

In *nervous* headache and headache from overwork, the grand desideratum is *rest* for the over-taxed organs. As with rheumatic subjects, those prone to *nervous* headache are like barometers, and feel every change of weather. The ordinary pressure of the atmosphere is 15 lb. to sq. inch, a fall of one inch (from 30 to 29) will take off ½ lb. pressure on every inch of surface, or about 1,000 lbs. over the whole body. If you go to top of Mont-Blanc, you reduce pressure by one-half.

Humidity and dryness have an equally marked effect. In dry air, moisture is given off by the skin, and thus the amount of fluid in the body is reduced, but in damp air this evaporation is checked. Thus, many people who have headache in low-lying damp swamps get well in dry air.

The electrical conditions of the air tend to influence the feelings of sensitive invalids, and when a thunder storm is imminent, many people suffer from headache, which is relieved when the storm has passed off. Again, a cold, raw, north-east wind blowing in the face will often give headache either to a person subject to rheumatic, congestive, or nervous headache. Thus travelling, often so beneficial, may become a source of evil.

The palliative remedies in many such cases are numerous. Eau de cologne and camphor water are often comforting. Ice is refreshing, or iced seltzer water; smelling salts to the nose, or snuff may be useful. A mixture of ether and aromatic vingar is grateful at times.

In dyspeptic headache, the pain is at the back of the eye, with a throbbing at the temple on movement. Care in diet is the grand requirement. If due to acidity a simple antacid and carminative, as soda with ginger, or rhubarb and magnesia, will do great good.

Sedatives are generally *bad*, they either fail to relieve, or stupify the patient.

In this lecture, I have felt it better to describe a few main varieties of headache clearly, so that you may realise the nature and treatment of each; although in practice each case may have something in common with two or more varieties.

Thus a nervous dyspeptic may suffer from sick headache, or a full blooded plethoric person from gouty and organic as well as congestive headache.

We cannot treat every case even of the same variety of headache on the same plan; every case is a study in itself, and that practitioner is the most successful who best adapts broad principles to the personal idiosyncracies of the sick person before him.

Do not neglect a headache nor attempt to remove it by a dose of opium, but—*find out its cause*—and *then* think no pains thrown away in removing it; few things are more easily dealt with in an early stage, and few maladies try the skill more when they have been long established.

Much may be done by judgment and discretion, and in a large proportion of cases cure may be counted upon if the effort to attain it is proportionate to the importance of the end in view.

The *prognosis* must depend entirely on the *diagnosis;* if there is organic disease of the brain recovery cannot be counted upon; happily, however, such cases are quite exceptional. In the *Rheumatic*, *Neuralgic*, *Congestive*, *Dyspeptic* and *Nervous* varieties, cure should be determinedly sought and found. In *Sick Headaches* alleviation and diminution of frequency in the attacks is certain. In *Gouty Metastatic Headache* the prognosis is less hopeful, and when the disorder depends on jaundice or deep-seated disease of distant organs, recovery from the headache must always be dependent on the course of the malady from which it springs.

Let me wish you all freedom from the disorder of which you have heard so much, and let me urge you, if you are so unfortunate as to suffer, to set yourselves to find out the *cause*, and, in many cases at least, the removal of the evil will then be easy.

ON SYPHILIS AS IT AFFECTS THE BRAIN AND NERVOUS SYSTEM.

By THOMAS STRETCH-DOWSE, M.D., F.R.C.P. Edin.,

Late Physician-Superintendent to the Central London Sick Asylum, Highgate; Physician to the North London Hospital for Consumption and Diseases of the Chest.

(*Continued from page* 360.)

DIAGNOSIS.

We have now to consider two other forms of syphilitic invasion of the nervous system, namely, one where the sympathetic ganglia are involved, and lastly, the peripheral nerves. Relative to the pathology of the sympathetic ganglia in syphilis, there is very little evidence at present to guide us. M. Pietrow, it appears, has been the chief investigator of the sympathetic ganglia in constitutional syphilis, and from his remarks it seems that there is a more marked pigmentation and colloid degeneration of the protoplasm of the ganglion cells, and a proliferation of the cells that form the capsules, and also a transformation of the interstitial cellular tissue into a more rigid and dense mass, which compresses the nerve-cells. If changes like these exist in, and arise from, constitutional syphilis—and, we certainly have no reason whatever to doubt M. Pietrow's conclusions—we can the more readily find an explanation for the cause of many of those functional troubles which

we are now unwilling to place under the designation, neurose. Up to the present time too little attention has been given to the pathological changes in sympathetic nerve centres, and great difference of opinion still exists as to the effect produced in the animal economy by such changes as well as in their absolute existence. The names best known in this field of research, according to Eulenburg, are Claude Bernard, Virchow, Traube, and Recklinghausen, Fournier, Wilks, &c. I believe that most of the ailments with vascular and trophic disturbances, as megrim and other conditions which are in many cases vaguely termed hysteria, merely indicate an unstable condition of the sympathetic nervous system in persons who are essentially the offspring of syphilised progenitors. Pathology has shown us that the doctrines taught, even by recent observers, concerning functional nervous disorders are no longer tenable. I think it must be admitted that the time has passed for us to consider chorea and paralysis agitans as mere functional nerve disorders, but how far functional troubles are due to acquired and hereditary syphilis, is certainly a question of considerable importance, and I am inclined to think they are of far greater prevalence than is generally admitted. Here we are, unfortunately, wanting in pathological proof, but the following cases, from a clinical point of view, are significant :—

Case XX.—*Vaso-motor Derangement—Recurring Storms of Sympathetic Symptoms—Absence of the ordinary signs of Hysteria—Menstruation Normal—Acquired Syphilis—Recovery.* "Abbreviated notes."

L. B———, æt. 34, has been under my care for some years. There is no neurotic history. She is short of stature, but well developed; there is neither lateral or angular curvature of the spine (but during the attacks there is general spinal hyperæsthesia). Menstruation is regular, and the uterus is, in all respects, normal. Has enjoyed excellent health until the past four years. When 26 years of age she contracted syphilis, and suffered from its effects for nearly twelve months. At the age of 29 she became so changed in character that her friends could not account for it; she was irritable, violent-tempered, and morose, and at the time of *her attacks* they seriously contemplated sending her to a lunatic asylum, as she was scarcely manageable. These attacks, the signs of which I shall briefly describe, were not periodic, neither were they associated with menstruation.

They were ushered in by increased irritability of temper, want of sleep, parched mouth, dry tremulous tongue covered with a thick whitish-brown fur, loss of taste and smell, as well as visual derangement. Pupils widely dilated; congestion of optic discs, as well as of sclerotic and conjunctival vessels; redness of the ears and of the face, sometimes unilateral or bilateral. Formications over the face, at times localised, at others diffuse; no vomiting. Constipation. Respiration hurried and panting, inability to take a deep breath. Pulse, 60; temperature very variable, occasionally reaching 105° Fah. Associated with these was cardiac and epigastric depression, and she complained greatly of a sharp pain passing through the abdomen as though the intestines were being torn out. The power to digest and assimilate was for the time in abeyance, and the intestines were usually distended with flatus. The head jerks about laterally from side to side. Has heavy hot perspirations and cold clammy sweats. The speech is jerky and syllabic. No objective paralysis or cramps of voluntary muscles. The urine is high-coloured, loaded with lithates, free from albumen. She usually remains in this state for a week, ten days, or a fortnight, then the tongue clears up, and, to use her own words, a load seems to be taken off her. After this, in the course of a few days, she is fairly well and getting about.

For some time I was much puzzled as to this woman's condition, and I certainly did not attribute the attacks as being in any way due to syphilis; on the contrary, I rather looked upon them as due to functional sympathetic depression inducing an hysterical or *abortive* epileptiform state, the cause of which I was at a loss to determine, until she came to me with rupial elevations all over the body. Anti-syphilitic remedies were prescribed and used persistently. This was nearly three years ago, and her health has remained remarkably good since.

Case XXI.—*Vaso-motor Paresis—Sympathetic Depression—Chronic Syphilis—Recovery.*

E. I., æt. 65, contracted syphilis when young, the remains of which are visible, as depressions of the skull and cicatrices of the scalp. She ceased to menstruate at 47 years of age, has never had a fit either hysterical or epileptic. There are no especial signs of degenerative change. No arcus senilis; no abnormal arterial tension; no albumen in the urine. She says that for the past eight years she has suffered greatly from depression of spirits, and at times thinks she is going out of her mind, and has a feeling as though blood was trickling over the eyes. There is no headache. The attributes of mind are normal. At times if anyone speaks to her suddenly, it causes her to tremble from head to foot, and produces profuse perspiration with a sense of heat and burning, and hot flushes of the head and face. Says she always feels better without food. After food she feels heavy and drowsy, and is distended with wind. When perfectly quiet she says there is not much the matter with her, but when she becomes excited there is a burning heat going down the left side to the foot, and extending from thence over the abdomen. After this the sensation becomes one of fluttering, and the bowels take on a swaying to-and-fro movement (as she compared it) like a bubble of soap floating on the water. This account to some may appear ridiculous, but a careful survey of disease of the sympathetic nervous system will explain this and a vast deal more. At first the valerianates and remedies of a like nature were persevered in with no good result. Anti-syphilitic remedies cured her.

Case XXII.—*Vaso-motor Paresis—Sympathetic Depression — Hypochondriasis — Syphilis — Recovery under Specific Treatment.*

C. G., æt. 33, a well-grown woman with no spinal distortion, good family history, says she contracted syphilis at the age of 29, and since this has never been well or menstruated regularly. For the past twelvemonths she has suffered more or less from unaccountable nervous symptoms, has dyspepsia after every meal, and when she first gets out of bed in the morning, the arms feel powerless for five or ten minutes. The sight becomes weak. There is violent palpitation of the heart, and she fancies that she will die suddenly. No organic disease can be detected. The urine is of normal gravity, free from albumen and sugar. Although she has never had a fit, fancies that she is going to have one. She suffers from periods of mental abstraction, and then suddenly becomes conscious to things around her and wonders what she has been thinking about. At other times she shows signs and symptoms which are usually attributed to hysteria. Amongst others there is the feeling as though cold water was trickling down the spine or being poured upon the back of the head. A feeling as of a flash of lightning striking across the eyes producing transitory blindness. The head feels too large, as though it would overbalance the body, and sometimes she feels as though she was made of cork. Flushings of the face and ears occur as many as twenty times during the day, succeeded by coldness and numbness of the extremities and clammy sweats. The treatment of this case consisted in the first place in the administration of bromide and iodide of potassium, and nervine tonics and stimulants with counter-irritation to the spine, and galvanism also, but no improvement took place. Mercurial salivation cured her.

Case XXIII.—*Vaso-motor Depression—Constant Vomiting—Incipient Mania—Syphilis—Recovery.*

S. T., æt. 27, of good family history, said she enjoyed excellent health until she was 22 years of age. At this

time she contracted syphilis, but did not suffer severely from it, but has never been well since. Menstruation normal.

At the age of 24, she was much worried and suffered from excitement, with tremblings in the inside which she was unable to explain correctly. They come on when she is suddenly spoken to, and usually accompanied with flushings of the face and a sense of burning on the palms of the hands and soles of the feet, which became bedewed with moisture. She is never free from headache and a constant burning at the top of the head, with throbbing and sounds of something "going click."

The attacks usually come on with violent agitation, thirst, dryness of the throat, intense burning pain extending down the spine from the occiput to the left hypochondrium, feeling of heaviness about the heart, distension of the stomach and intestines, with flatus, general suffusion of eyes, ears, and face, furred tongue, offensive breath; respiration, hurried and panting. Pulse and temperature very variable. The legs and feet are usually cold and so painful that she cannot bear to have them touched. The bowels are constipated and vomiting most persistent.

There is sometimes albumen and blood in the urine. This is not due to organic renal change, but to a paresis and want of tonicity in the renal vessels, for as the attack passes off, the urine becomes perfectly normal. The optic discs are clear.

When I first saw her she said that she had been suffering from these attacks every six weeks or two months, and at times she became violent and almost lost her reason. Anti-syphilitic remedies were not at once adopted in this case, but measures were resorted to in order to improve her general health and equalise and control vaso-motor energy and correct functional disturbance, but all to no purpose. Gentle prolonged ptyalism cured her.

I have records of a considerable number of cases similar to these noted, in which at one time I took an especial interest, and where the etiology was obscure, unless it were referred to the sympathetic ganglia, and in a large number of these there was a decided syphilitic history, and they yielded only to appropriate treatment.

(*To be continued.*)

THE INNER LIFE AND ECONOMY OF A LOCK HOSPITAL IN INDIA. (*a*)

By Surgeon-Major W. CURRAN,
Army Medical Department.

(*Continued from page* 482.)

So much for the hospital and its surroundings. Let us now turn aside for a moment, and inquire into the condition, social and otherwise, of the women for whom it has been prepared. Let us, in other words, descend from our stilts, and study the *vie intime* of an Indian prostitute. The subject may not be a savoury one, but that is no fault of mine. I must take things as I find them, and the wisest course in this and other matters medical is "to tell the truth and shame the devil." I have already said that she is often more sinned against than sinning in the selection of her calling, or rather that she is, probably in ninety cases out of every hundred, the victim of an arrangement or a necessity that has been impressed upon her by her birth. I have also hinted that she does not appear to be dissatisfied with her lot, or desirous of changing the same. On the contrary, she is indifferent, or hopeful, as the fancy takes her, or the market directs. She take the easy epicureanism of Tibullus for her motto, without knowing what it means—

. . . . . Credula vitam
Spes fovet, et fore cras Semperait Melius;

and there is no doubt that, whatever inconvenience may attach to her life in private, she is not subjected in public to that censure, or contempt, which is so often, and so unsparingly, dealt out to her sister in the cooler West.

She earns (*a*) quite as much, and often much more, than her virtuous neighbour, especially so, if to the *rôle* of prostitute she adds that of dancing-girl—no uncommon combination. She occupies as good, or at times a better, house than the poor, but more virtuous, native woman of the same class; and she is altogether free from the toil and seclusion which caste, prejudice, or necessity imposes on the latter. In short, her life is, from her own stand-point, neither unprofitable nor unpleasant. She has long since cast shame and conscience—if she ever possessed either—to the winds; and what I have seen of her health and physique during the past year, inclines me to believe that there is nothing in her office that tends to shorten life, or diminish her enjoyment of it. She lacks, of course, the ease and polish of a Western training. She does not assume the airs, or approach her *employès*, like a London or a Parisian favourite—

Qualiterin thalamos formosa Semiramis esse
Dicitur, et multis dais amata viris.

She is not, on the other hand, so subject to the ups and downs of fortune as is the home article, or so dependent on the changing hues of a "foolish face;" and like the former she often marries in a sphere above her. But we need not carry the comparison any farther; it is not in either case a very savoury or edifying one; and I will only add in this connection that these Indian women can support themselves, after their fashion, on a pittance for a year, which would scarcely satisfy their more fleshy or exacting English sisters for a week.

As regards her other habits and liabilities, she is often a confirmed opium-eater or bang-smoker, though the former failing is much commoner than the latter. Nor does either indulgence exercise, as far as I may judge, any very appreciably injurious effects on her sexual appetites or generative powers. (*b*) These women menstruate

(*a*) It may be necessary to explain, for the benefit of those who do not understand Hindoostani, that the word "purka" means, in reference to a well, wall, or building, masonry, as distinguished from clay; while the words "dhai," "chowkedar," and "bhistie," mean respectively a nurse, a watchman, and a water-carrier.

(*a*) I have come to the conclusion, after much inquiry into, and examination of, the point, that 6 rupees, or about, say, 12s. to 15s., constitutes the average monthly income of the public women of this station. Many, of course—especially so those *quæ decurionibus anglicanis versantur*—earn much more; but others—the less fortunate or favoured ones, who are obliged to consort with natives or private soldiers—earn, I am satisfied, considerably less than this; and 4 annas, or 6d., is "a legal tender" on the part of a European soldier for the services of a registered prostitute. How different is all this from what one sees or hears of this class at home; and the drought has greatly enhanced their troubles. Verily—

It is the pasture lards the brother's sides,
The want that makes him lean.

And I often feel humiliated when these poor creatures tell me that they cannot get a living even on the terms, or at the terrible sacrifice they make, for it. Small as this income is, yet it is larger than that which accrues, from all her toil, to the poor virtuous villager, as appears from the following extract, which I take from the last census report of the N. W. Provinces:—"At a distance from towns, the ordinary wage of an agricultural labourer, almost invariably a married man—I refer more particularly to the Allahabad district—is, in the ploughing season, 1 seer 9 chittaks (equal to 50 ounces) of *behjur* (a mixture of grains). When digging and weeding he gets about two-thirds of the above quantity. The wife is also occasionally employed in light field-work, and when so engaged she gets from 25 to 30 ounces of *behjur*. The husband, in addition, receives about 2 *rupees, either in coin or its value in grain, once a year*, from the zemindar as a retaining fee. *The above constitutes the highest daily earnings* of man and wife when in regular work; but during the hot season, and occasionally throughout the year, field hands are not required, and the family subsist on the irregular earnings of the husband while employed in repairing houses, &c., in the village. Should the husband become sick, no rare event, *absolute starvation stares them in the face.*"

(*b*) Having lately read in an article, "A Run Through Kathiawar," that appeared in "Blackwood's Magazine," for October, 1876, p. 404, that "One injurious effect of the habit of opium-eating, which the Chief admitted, was sterility in their families," I inquired into the circumstance, and find as above—that, as far as can be gleaned from the facts at my command,

Statement of the Quantity of Crude and Prepared Opium that is Consumed every Month by 14 Eaters and 5 Smokers of that Drug; including also some account of its Cost and and Mode of Preparation.

Classification of consumers		Average cost of the article.		Amount of either consumed monthly.		Remarks.
Eaters.	Smokers.	Crude opium.	Prepared opium.	By those who eat it.	By those who smoke it.	
14	5	One chittack—an Indian measure, which is equivalent to 2 oz. Avoirdupois—costs 1 r., or in other words, about 1s.	A tolah of this equals 3 ds. Avoirdupois; costs 1s 8as., or something about 1s. 2d. English.	These 14 women consume on an average 2 lb. 1 oz. 3 ds. of crude opium between them every month.	These smokers consume in the same time through a hooka or bubble-bubble about 4 oz. 4½ ds., or, say roughly, 1 oz. each all round.	The prepared opium—viz., opim made into an extract like tobacco by means of guava or betel leaves—is much dearer than the crude article. Hence the greater consumption of the former. But the cost is nearly the same to both classes of consumers—viz., 16rs. 9as. to the one, and 16rs. 14as. to the other, or an aggregate total of 33rs. 7as between these 19 women. In other words each woman spends on an average 2 rupees each (4 shillings) monthly in this drug.

regularly, and apparently without any serious discomfort or suffering. Many of them have borne healthy children, and one, at least, of their number is now *enceinte*. They rarely complain of those ill-defined or anomalous aches and pains that are so common among females elsewhere. Their uteri are rarely altered, either as to size or situation; and speaking generally, they appear to me to enjoy more immunity from the infirmities of their sex, than falls to the lot of European women out here, or than is enjoyed by their congeners in the West. They are altogether free from many of the uterine ailments which civilisation has developed in Europe, or a more artificial life has intensified everywhere; and I have often been surprised at the absence of change in these parts, which I have noticed during my incumbency here, in these women. But these points had, perhaps, better be summarised in a table, than dwelt on categorically in this place; and I have constructed a form accordingly, which will explain, or enforce, them better than I could hope to do without extending this already too lengthy paper unduly. This is, moreover, my usual mode of acquiring or imparting information on minute technical details, and any or such comments as the situation may indicate or require, can be squeezed into the column of remarks hereafter.

this indulgence exercises no such injurious effect on these women's powers of gestation, as might be supposed. But then the facts are too few for a deduction, and the habit is more cultivated by the older than the younger women. Of the 36 women who acknowledged to me that they habitually ate or smoked this drug, 22 were over 30 years of age; while 10 were under that age, and 4 others appeared to be under 20; and the following rough table—which is based on some inquiries that were made for me, by my native subordinate, among 19 confirmed eaters or smokers of this article—may prove interesting:—

TABLE No. 9 *shows thoroughly the History, Habits, and other General, or Sexual, Characteristics of* 83 *Indian Prostitutes.*

No. examined.	Probable age of these women.	No. of each class observed.	Previous history.		Present condition.				Other sexual peculiarities, or conditions, of these women.	Remarks.
			Fertile.	Barren.	Menstruation.		Habits.			
					Normal.	Abnormal.	Opium eaters.	Bang or Wine Drinkrs		
83	Over 30	37	24	12	32	2	22	3	One woman has a cyst on the right side of the vagina, which has not been explored. Another, a pregnant woman, has a large fleshy polypus protruding from the os, which is greatly increased during the menstrual period. And three, or more, examples of the condition which I have called nævus of the os have been met with during the year.	Premising that this table—though I have done my very utmost to insure accuracy—is at least but an approximation to the truth, I proceed to say that I infer barrenness rather than actually assume it, from an absence of child-bearing in women who are otherwise capable to all appearance of bearing children; and it does not, of course, follow that those who may not have given birth to children are, *ipso facto*, barren. It will be seen from the table that at least 76 of these women, or at the rate of about 90 per cent., menstruate regularly; while the number that does not is very small; and one or more of the younger women appear uncertain on the point. The 37 cases of opium eating, or bang or arrack drinkers, include those noted from time to time during the year; and the use of these articles is occasionally discontinued in obedience to the requirements of the market, or the circumstances of the consumer. My native subordinate fancies that the women who habitually indulge in this habit are paler or more lethargic than their neighbours; but I have not been able to verify this impression.

Special Articles.

HYDROPHOBIA IN LANCASHIRE.

CONSIDERABLE interest, and almost excitement, has been roused in Lancashire by the announcement in the daily local papers, of two reputed cases of rabies at Oldham. Some of the paragraphs referring to the occurrence have been of the most sensational and inaccurate character, and nervous people may probably suffer from reading such exaggerated descriptions of the symptoms and condition of one of the patients. It is unfortunately true, that Dr. Patterson has had under his care two patients, pronounced by competent observers to be affected with

this much dreaded disease, and we are enabled, through his courtesy, to furnish some particulars in anticipation of a more detailed and extended report which will shortly be published.

On Sunday, April 28, a rabid dog gained access to the Oldham Workhouse and attacked one of the inmates, tearing his coat to pieces. The man, thereupon, procured an iron bar and struck the animal on the head, and thinking it belonged to some of the Union officials, he quietly went away, leaving, as he thought, the dog in a dying state. The animal was subsequently discovered in a lobby leading to the kitchen. The porter and his wife repeatedly passed it, and a young woman, a friend to dogs, having heard that the animal had been struck, gently patted it on the head, without exciting the animal to bite her. Owing probably to its being disturbed by some passers-by, the animal wandered into an open yard, through which the inmates had to pass to the church. Here it bit the two patients John Carr and Eda Williamson. It would probably have injured others, had not a pauper, named Greenwood, seized a crowbar and killed at one blow, the rabid animal. Though efforts have been made, the owner of the dog has not been traced, nor is it known where the animal came from.

Case I.—Eda Williamson, æt. 9, bitten on left eyelid and left side of the nose. The wound was immediately attended to, cauterised, and healed without any difficulty. The girl's health continued unimpaired until Tuesday, June 4th, when the schoolmistress noticed that she seemed a little depressed. On Wednesday, June 5th, she was admitted to hospital, though there were no special symptoms ; she only complained of *malaise*. On Thursday, the characteristic symptoms developed, consisting of difficulty of swallowing, dislike to drink, &c., &c. She was conscious in the intervals of the paroxysms, smiling and laughing, and died suddenly at half-past three on Thursday, June 6th, whilst Dr. Patterson was taking her axillary temperature, which at its highest reached 101·4°. A *post-mortem* was made, 24 hours after death, by Drs. Patterson, Lauder Brunton, and Professor Gamgee ; a detailed report of which will be published. We may, however, state that the implication of the medulla oblongata pointed out by us in our "Report on Rabies and Hydrophobia," has been further confirmed by the *post-mortem* disclosures. This case presents some features of interest, as regards period of incubation (37 days), time of death, situation of wounds, &c., and we have no doubt these and other salient points will be noted by the medical attendants.

Case II.—John Carr, æt. 19 or 20, bitten same day (April 28) on hand ; the wound was cauterised immediately, and healed in the usual way. Though he was carefully watched, no symptoms of ill-health were noticable until June 6, when a complete change of manner indicated that he was poisoned. He was characterised previously by his active habits, cheerful, and even noisy disposition, but he now became silent, reserved, depressed, and a complete change of his *morale* took place. He was at once ordered to bed, and Dr. Lauder Brunton telegraphed for. An immediate response was made by this distinguished expert, as he reached Oldham on Thursday night and at once commenced with his special treatment.

This patient was delirious, his delirium running on dogs, and he tossed about the bed, making noises with his hands as if calling an animal to him ; pupils contractile ; countenance dusky, with restlessness and sleeplessness. The difficulty of swallowing, spasm, and paroxysms were not so pronounced as in the first case, though yet sufficiently marked to establish the diagnosis. Dr. Brunton remained twenty-four hours, and was enabled to leave the patient in a more promising condition. The highest temperature during his illness was 99°, the highest pulse, 106. Thermometrical observations and sygmographical tracings were made. The mucous membrane of the throat was in a highly congested condition, and the uvula and arch of the palate inflamed and enlarged. This condition had not subsided when we saw the patient on Tuesday, June 11th. Though fairly on his way to convalescence, there was a peculiar expression of face as though he had been stupified, or was recovering from some narcotic ; this could not in any way be attributed to any medicine administered ; he was also suffering from suppression of urine, which might account for the appearances noted above. Dr. Patterson had drawn off 6 ozs. of urine in the morning. When we saw the wound on the hand we remarked its peculiar purplish appearance, though it was not painful on pressure, nor had it been so since cicatrisation. Up to the present time the patient is steadily improving, the graver symptoms disappearing, and the man's ultimate recovery we may only regard as a matter of time.

It affords us pleasure to be able to lay before our readers these brief notes, and we think they offer a sufficient encouragement to medical men not to look upon rabies as hopeless and incurable. Whatever difference of opinion there may be as to designating this case as a pure typical example of rabies there cannot be the slightest doubt that this patient was, in every sense of the word, *poisoned ;* and that the symptoms, on the evidence we have, are fairly attributable to a specific virus, which, in the majority of cases, has hitherto led to speedy and certain death.

It has been the fashion, because cases have recovered, to doubt their authenticity ; and the case lately under the care of Dr. Nichol, Chelmsford, has been disputed. In *The Times* of June 8th Dr. Prater remarks, some alteration must be made in our laws before the problem of hydrophobia can be satisfactorily solved ; and this conclusion, he says, he arrived at after reading "the last useful work on the subject"—the "Report of the Medical Press Commission." He has generously offered a prize of £100 to encourage investigation into the disease. One of the simplest and most important requirements we have pointed out—viz., the desirability of establishing a correct diagnosis ; and we have suggested the necessity of extending the powers of the medical officers under the Privy Council, so that when we have a case of recovery reported, it may be placed beyond all dispute.

At present a number of scientific and philanthropic physicians have offered their services, and at considerable expense and pecuniary loss, have assisted in the treatment of several cases. Such noble devotion to science is more than praiseworthy, but it must have a limit ; and we cannot expect this committee to sit *in perpetuo*.

Rabies is a national question, and we may fairly expect some assistance from Government, especially in the manner pointed out, as it will only entail a modicum amount of expense. We must express our indebtedness to Dr. Patterson for his kindness in furnishing us with all particulars, not only as to facts, but as to the treatment adopted. Though we have designated it as special, we do not suppose Dr. Brunton desires to give it that name, but we consider it only fair, that Dr. Brunton himself should describe his own treatment, both as to its nature and *rationale*. Our examination has satisfied us of the serious peril in which the patient had been.

DANGER FROM THE HYPODERMIC INJECTION OF MORPHIA.

E. F. Ingals, M.D., Chicago, publishes an interesting paper on this subject in the *Chicago Medical Journal and Examiner*, May, 1878, p. 491, based upon replies which he received to a circular sent out by him, to eighty representative physicians of the North-west. Fifty-five gentlemen replied to the circular, which was couched in the following terms :—

"Have you often given hypodermic injections of morphia ?"

"What is your ordinary dose of morphia when used in this manner ?"

"Have you ever seen syncope or other unpleasant results follow its administration by this method?"

Nearly all had used hypodermic injections frequently in doses varying from one-sixteenth to half a grain, in exceptional cases one grain. Two recommended from one-sixteenth to half of a grain. Three did not exceed one-sixth of a grain. The majority were accustomed to give from one-sixth to one-fourth or even one-half of a grain. A few combined atropia with the morphia for injection. Thirty-four of the fifty-five had seen no unpleasant results, and six had seen nothing worse than abscesses at the point of introduction.

The remaining fifteen were unfortunate in their experience, and the results observed by them, serve as a warning against making too light of the dangers attending this method of administering morphia. Seven fatal cases were reported. In all, save one, the ordinary dose had not been exceeded, although in some the exact quantity had not been noted. One death was caused by the injection of one-fifth of a grain of morphia, combined with one-seventy-fifth of a grain of morphia. Another resulted from the administration of two doses of morphia of one-third of a grain each, with an interval of four hours between the first and second dose. The case was one of invaginated intestines. Death from narcotism ensued six hours after the second dose. Another resulted from one-fourth of a grain given in a case of sciatica, the patient dying comatose within five hours. Another death is reported as following the administration of two doses of one-fourth of a grain of morphia, the first taken internally, the second administered hypodermically.

Another, a case of myalgia of the muscles of the back terminated fatally in the course of twelve hours, having been first subcutaneously injected with 1-60th of a grain of sulphate of atropine, then given by mouth ¼ of a grain of morphia, and finally, the pain being still exceedingly severe, being injected hypodermically with ¼ of a grain of morphia.

The exceptional case alluded to was a patient upon whom the operation of ovariotomy had been performed. The amount of morphia in this case was not determined exactly, but is estimated at 1½ grains given in the course of five hours, in two doses of ¾ of a grain each. Narcotism followed the last dose in from fifteen to twenty minutes, terminating in death within two hours.

Amongst the replies received by the author to his circular he quotes the following at length.

"I think there is always more or less danger from the use of morphia in this way, so have almost discarded its use."

"I am chary of the use of the syringe, using it when demanded—dose gr. ⅓. Largest dose ever ventured on was gr. ½ (in violent colic). The patient was asleep in one minute and did not awake for sixteen hours. No bad results."

"I have seen unexpectedly severe effects on several occasions. I do not give morphia in that way when I can give it by the stomach. The effects that I speak of were simply severe ordinary effects of the medicine."

"No syncope, but in my experience results have been so uncertain and unexpected that I now never resort to the surgical operation to introduce medicine when the patient can swallow, or has the use of the rectum. I should as soon think of introducing food as a regular thing by transfusion of blood. Put me down as opposed to the practice save in exceptional cases."

"Once, after ⅛ of a grain, syncope occurred in about fifteen minutes after administration; was given in a case of cholera morbus."

"One case, the patient slept twenty-four hours. . . . . The dose was only 1·12th of a grain."

"But once, gave ½ gr. to adult male (in case of compound comminuted fracture of tibia and fibula) to ease pain. While administering injection sudden collapse and dyspnœa, with fluttering heart. Rallied under ammonia and whisky." . . .

"In the case of an old lady nearly eighty years of age, there was almost instantly after the injection a frightful degree of numbness, as she expressed it. (The dose gr. ¼.)" . . . .

"Have seen alarming syncope in three cases, great prostration in a score at least." . . . . .

In conclusion, Dr. Ingals directs attention to the fact that, although this method of administering morphia may have been used a thousand times successfully, yet the next time fatal consequences may ensue, and that even the fact of its having suited a particular patient on former occasions will prove no safeguard against its not doing so on subsequent ones. It must therefore be used with caution, and those using it must be prepared for emergencies.

Special Correspondence.

[From our Special Correspondent].

Paris, Rue de Luxembourg,
June 14th, 1878.

In my last letter I made a cursory allusion to the International Congress of Hygiene. Sanitary science must be advanced by the mutual interchange of ideas and experiences of the hygienists of various countries, and as the Medical Press and Circular has taken a very active and prominent position in the advancement and encouragement of hygiene, fulfilling the very excellent motto of the journal "*Salus populi suprema lex*," I therefore send you an abstract of the programme issued by the Committee who have organised the scheme.

I. Formation and object of the Congress. Art. I.—An International Congress of Hygiene, under the patronage of the French Government, will be held at Paris in August, 1878. Art. II.—The object of the Congress is, to bring together the *savants* of all countries, desirous of discussing questions relating to the progress of hygiene. Governments, administrations, scientific societies, corporations, are invited to lend their aid to the project by sending delegates.

II. Work of the Congress.—Art. III.—The Committee have determined to discuss a certain number of questions, included in the annexed programme. A memoir on the exact state of our knowledge on these questions, will be published by the Committee, and will be sent to all subscribers at least a month before the opening of the Congress. Art. IV.—Other interesting hygienic subjects will also be submitted for consideration. Authors must send their papers at least a month in advance. Art. V.—Two sittings will be held daily; the first from nine to twelve, for questions introduced by individual members, the second from two to five, for the discussion of the subjects proposed by the Committee. Art. VI.—Speakers must not exceed 15 minutes, unless by consent of the assembly. Art. VII.—The work of the Congress will be published by the Committee.

III. Constitution of Congress. Art. VIII.—The Congress will be composed of subscribers, national and foreign. Art. IX.—Home members will be charged 20 frs. and will have a right to all the publications. Art. X.—Foreign members will be admitted to the Congress free of charge.

Questions fixed for discussion in conformity with article III.

I. "The Hygiene of Newly-born Children," as regards mortality prevention, &c., introduced by MM. Bergeron, Bertillion, Margarin. II. "On the Alteration of Water Courses," as regards their corruption by industrial products, drainage, &c., introduced by MM. Durand, Claye, Proust, Schloesing. III. "The Hygiene of Food," introduced by MM. Bouley, Nocard, Bouchardat, and Gauthier. IV. "On the Dwellings of the Necessitous Classes," introduced by Trelat and Du Mesnil. V. "Professional Hygiene;" Reporters, M. Gubler and Napias. VI. "The Prophylaxis of Infectious and Contagious Diseases." What are the transmissible maladies requiring the isolation of patients in general or special hospitals, and how reconcile this isolation with the practical rules of the service? Reporters MM. Fauvel and Vallin. For the morning meetings the Committee have selected some other questions, as the prophylaxis of rabies, mortuaries, cemeteries, cremation, the ventilation of schools, the hygiene of prisons and of light.

Dr. Bouchardat is Honorary President, Dr. Gubler, Pre-

sident, and Dr. Lioniville, General Secretary, to whom all communications should be addressed.

It may be interesting to medico-psychologists to know that their special branch will not be neglected, as arrangements are being made to bring together the alienists of all countries. Paris is a fitting place for such an assemblage, for her physicians hold a high and proud position in connection with insanity, and the traditions of her school of alienists are well preserved by her present representatives in psychological medicine.

Medical men are interested in the literature, and we have many worthy representatives amongst the fraternity of letters, so that the subject of copyright has a professional interest. The International Literary Congress, convoked by the Gens de Lettres Society, held its first meeting on Tuesday, the 11th, in the Masonic Hall of the Rue Cadet. M. Edmond About, who was in the chair, said he only represented temporarily the illustrious president, Victor Hugo, with whom the idea originated, of inviting literary men of all nations to meet together, to discuss at once their interests and those of literature. No patronage of such a work could be so unexceptionable as that of Victor Hugo, whose political was quite secondary to his literary fame. In the last century writers lived by tolerance, and could only flourish by the aid of a patron. Voltaire and France had taken the lead in their emancipation, and now in France and many other countries literary men were not only able to live and keep their families by their labour, but many of them had made great fortunes and enjoyed the highest social consideration. He would like to see extended to every country the same rights and privileges which they themselves enjoyed. He did not mean that at present they should ask for Russia the same liberty of the press as in Fance, nor even that France should have as much liberty as England. These were separate questions. But what he thought practical was general legislation, by which foreign authors should enjoy in every civilised country the same rights as the natives. At present copyright was ill-defined, and the cost of fulfilling formalities to claim it often more than any possible profit.

M. Zacone, the secretary, then read letters from the Austrian, United States, Italian, and Portuguese Ministers, expressing sympathy with the movement. England, Germany, Austria, Brazil, Portugal, Denmark, Sweden, Norway, the United States, Italy, Holland, and France were declared present by representatives. A president and secretary for each nation were selected. Those for England were Mr. Tom Taylor and Mr. Blanchard Jerrold. The Congress was divided into three committees, named summarily by M. About, legal, diplomatic, and social. Every delegate, on his name being called, stated to which committee he preferred to belong. M. About said that the Congress would meet till further orders in the present locality, but that when some thousands of the public came to hear Victor Hugo, another place must be found.

I promised a sketch of the Service de Santé de l'Armée de Terre of France. The military medical service should be an index of the civilisation of a country. The French medical service since it was first regularly formed, by an edict of Louis XIV., Jan. 17, 1768, has undergone many gradations, both as regards organisation, duties, pay, rank, &c., keeping pace with the requirements of more modern times, and a higher appreciation of the importance of army surgeons. The competitive system is adopted, and the terms for admission to the military medical schools are set forth in a presidential decree of October 5, 1872, and further ratified 25th April, 1878. Competitive examinations are held yearly in September for admission as *Elèves du Service de Santé Militaire;* and the successful candidates are divided according to their choice and convenience, in the following towns to prosecute their studies, viz., Paris, Montpellier, Nancy, Lyon, Marseille, Toulouse, Bordeaux, Rennes, Lille, Besançon, Grenoble, and Alger. Candidates are allowed to compete who are—1st. Possessed of two diplomas, Bachelor of Arts, and Bachelor of Science. 2nd. Or who have four, eight, or twelve certificates (inscriptions) available for the doctorate, and have passed successfully the examinations at the end of the year, corresponding to the number of their certificates.

Other regulations apply to nationality, age, aptitude for medical or military service, whilst an engagement must be entered into, that, if successful, ten years of service will be completed, dating from the grade of aide-major of the 2nd class. After these formalties are complied with, the candidates undergo an examination varying with age and certificates they possess. The subjects are Natural History, Chemistry, Elementary Physiology, Osteology, the Articulations, Myology, Descriptive Anatomy, General and Special Pathology. Successful candidates are classed in order of merit. *Elèves* who have less than twelve inscriptions, can complete their studies in one of the towns mentioned, under the direction of the appointed teachers. No uniform or pay of any kind is provided, and all expenses for instruments, books, must be defrayed by the pupils. A subvention is, however, allowed to *boursiers* of the Prytaneum, of 1200f. per year. if at Paris; 1,000f. at Lyons or Marseilles; and 800f. for all other towns. Students who have more than twelve certificates are placed under the director of the School of Val de Grâce at Paris. During their first year at Val de Grâce two examinations for the Doctorate have to be passed, and when they have undergone the three last examinations, they receive uniform and pay amounting to 2,512f per annum. This I may call the first stage, where for the present I shall leave them.

The above programme does not look very inviting, for the pecuniary prospect is not very great, while the examinations are severe, and the regulations strict. For if not successful, or dismissed, the pupil has to defray all expenses incurred in his training. We must remember that money has a higher value in France than in England; that the average receipts of the French general practitioner are very much smaller than those of his English *confrère*, so that a professional income of £500 a year is looked upon in France as a very high and satisfactory one, whilst most young practitioners in England consider it a very poor pittance to even exist on. We must also allow for the military feeling of the nation, and for the love of the army shared by all Frenchman and Irishmen.

The English Medical Service was popular with Irish gentlemen, even when the pay was less than it is now, though, for causes I need not enter on, its popularity has waned, for educated Dublin graduates do not now seek admission. The degree in arts required in the French Medical Service seems to me a *desideratum*, and I observe Professor Haughton, in your issue of June 12th, has suggested the desirability of extending the competitive examination to classics and science, as well as medicine and surgery.

The opinion of such an authority must be well worthy of consideration, for certainly, putting it very mildly, the classics—

Emolliunt mores nec sinunt esse feros.

Medico-Parliamentary

MEDICAL ESTABLISHMENTS.

In the House of Commons on Thursday last, in Committee of Supply, on the vote of £256,500 for Medical Establishments,

Mr. Parnell asked whether this vote included any charge for the hospital service of the Brigade of Guards.

Colonel Stanley was unable to speak with certainty as to the whole of the items, but if the hon. member would repeat his question on report care would be taken that definite information should be given.

Mr. Parnell said the hesitation on his part in accepting the offer of the right hon. gentleman arose from a fear that it would be impossible to give any satisfactory explanation. A total change in system seemed to him to be the only remedy for the state of confusion into which matters had got. There was a sum of £8,000 which had formerly appeared under another vote hidden away somewhere, and the Secretary of State did not know where.

Major Nolan said there was one important point to which he wished to draw attention, and that was the manner in which medical gentlemen in the army were treated. As many of the army surgeons were drawn from Ireland it was a question of great interest to Irish members. A letter which appeared in the papers about a week ago set forth that there was a want of medical officers because they felt aggrieved at not being allowed

to be members of the regiments to which they might be attached, and were not allowed to be members of the regimental mess. They were thus only able to obtain on sufferance advantages to which they ought to be entitled as by right.

Colonel STANLEY said the whole subject of the medical service had been carefully considered in the time of his noble predecessor, with a view to ascertaining what were the difficulties in the way of obtaining a proper supply of medical officers for the army. The present system had been adopted after great pains had been taken in the re-arrangement of the medical service of the army upon a basis very distinct from that which had obtained before. He was not prepared to admit that it was in the army alone that medical men were to be found who were dissatisfied with their present position; and as to shortness of numbers, that was a difficulty from which other services were also suffering. Government, however, were doing their best to increase the strength of the department.

The vote was then agreed to.

REGISTERED FOR TRANSMISSION ABROAD.

THE
MEDICAL PRESS AND CIRCULAR
Is published every Wednesday morning. Price 5d. Post free, 5½d.

POST FREE TO ANNUAL SUBSCRIBERS £1 2 6
,, IF PAID IN ADVANCE 1 1 0

*** Post-office Orders and Cheques to be drawn in favour of—
A. A. TINDALL, 20 King William Street, Strand, London, W.
A. H. JACOB, 3 Molesworth Street, Dublin.
MACLACHLAN and STEWART, South Bridge, Edinburgh.

SUBSCRIPTIONS FOR FRANCE are received by Messrs. BAILLIERE, Rue Hautefeuille, Paris—post free in advance, £1 3s. 6d. per annum.

SUBSCRIPTIONS FOR THE UNITED STATES are received in New York, by Messrs. WILLMER and ROGERS; Baltimore, by Messrs. KELLY and PIET; Philadelphia, at the *Medical and Surgical Reporter* Office, post free in advance, six and a-half dollars (£1 3s. 6d.) per annum; or direct from the Offices in this country for the same amount, if remitted by International Post-office Order.

The Medical Press and Circular.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, JUNE 19, 1878.

THE FLESH OF DISEASED ANIMALS AS FOOD.

CONSIDERING the comparative scarcity and high price of all kinds of animal food, and the increasing demand for it by a large section of the community, it would be unwise to place more severe restrictions upon the preparation and sale of meat than are necessary to prevent its being sent to the market in a condition detrimental to the public health. And yet there are certain facts constantly coming to the notice of our sanitary authorities which make it imperative upon them to place greater restraint upon the sale and slaughtering of cattle than that which now obtains, and—with the view of not depriving the poor of an important article of diet more than is absolutely necessary—to consider whether or not the whole of an animal which has died from disease is unfit for food.

The sale of diseased meat throughout the country is carried on to such an enormous extent that Dr. Cameron will shortly call the attention of the House of Commons to the subject. It is said that the transactions of some London dealers in diseased meat amount to many thousands per annum; that the destination of this meat is the small retail butchers in the poorer and more densely populated districts of the metropolis; and that thirty tons of diseased beef, mutton, &c., are seized and destroyed in the course of a single season. Nor does this last-mentioned fact give an adequate idea of the actual amount of bad meat consumed by the labouring population, as doubtless the above quantity of condemned meat, large as it appears, forms but a small percentage of that which escapes the eye of the sanitary inspector, or that which, in a less repulsive form, is openly sold to all classes of customers. This, however, cannot be wondered at, considering there is little or no Government supervision over the sale and slaughtering of animals for food. Even in the more wealthy parts of the metropolis we have no guarantee that the meat bought comes from an animal that was sound and healthy before it was slaughtered. In the more civilised parts of the Continent precautions have been taken to safeguard the public from the consumption of unwholesome food. The establishment of public *abbatoirs*, the official inspection of the animals brought to the shambles, and the appointment of licensed slaughtermen and skilled veterinary superintendents have been found efficient barriers against those evils and abuses which have become common in this country.

But while it is to be hoped that some legislative measures will be taken to remedy the evil complained of, it is no less desirable that the measures adopted are not of a too summary a nature, and that nothing is done which is not warranted by the experience of our sanitary authorities and the opinion of our most eminent veterinary surgeons. For it is very questionable whether all the flesh of an animal which has been killed soon after the detection of some local disease should be condemned as unwholesome food; and yet there is a popular idea (to which a leading daily paper gives expression) that no meat is fit for food unless it comes from the carcase of an animal that is wholly sound at the time it was slaughtered. As an able writer in the *Veterinary Journal* has recently remarked, the wide prevalence at times of certain diseases, and the pecuniary value o the diseased animals, make it a question of no mean importance whether it is justifiable to condemn as unfit for human food all the flesh of the animals suffering from them; and this question should not be decided on mere theoretical or sentimental grounds, but on the teaching of everyday experience. "It has been fully demonstrated that such maladies as septicæmia, anthrax, and glanders render the flesh very dangerous as food, while there is no reliable evidence to show that the flesh of animals affected with foot-and-mouth disease, pleuro-pneumonia, or cattle plague has ever produced the slightest injury or inconvenience to those who partook of it." Such, at all events, is the opinion of the veterinary authority above mentioned,

an opinion which is strongly supported by that of many eminent writers both in this country and on the continent. Some time ago, the MEDICAL PRESS AND CIRCULAR called attention to some rather startling statements that have been made by men whose judgment in the matter is entitled to some respect, and as the subject is an important one, we shall again quote them, without, however, wholly assenting to the conclusions at which they arrived. Regnal states that the flesh of animals who have suffered from pleuro-pneumonia has been in daily use in Paris for the past twenty years without any appreciable results. Loiset states that, during nineteen years, the flesh of 18,000 diseased animals has been used as food in Lille, and that during that time there was no appreciable alteration in the death-rate, nor any unusual accession of disease. Mr. Gamgee states that in 1862 more than one-fifth of the meat consumed in Edinburgh was that of diseased cattle, and yet that year was not one of unusual mortality. Dr. Greenhow, in the report sent in by him to the President of the Board of Health, in 1857, states: "I have been unable to ascertain that eating the flesh of animals that have suffered from pulmonary murrain produces any injurious consequences on human health." Dr. Druitt, of London, states that he "never saw any case of illness arise from eating the meat of diseased animals." Lèvy, in his "Traité d'Hygiene," quotes instances of the consumption of similar diseased cattle on a large scale, with no injurious effect; and Coze, in the Memoirs of the Agricultural Society of Paris, gives similar instances of the wholesale consumption of diseased flesh in Strasburg. Huzard and Frank might be quoted also in the same connection. Mr. Fleming, in his work on "Veterinary Sanitary Science," says, in speaking of pleuro-pneumonia: "Since the malady has been recognised it may safely be asserted that the flesh of millions of diseased animals has been consumed as food in every part of the world, and yet there is not, to my knowledge, a single instance of any accident attending or following its use."

It will be observed that the above authorities use the terms "diseased cattle," "diseased meat," without any qualification as to the nature of the disease from which the animal may suffer, thereby making a generalisation respecting the truth of which they fail to adduce sufficient evidence. That, however, all the flesh of unhealthy animals is not so pernicious as is generally supposed is shown by the small amount of disease that can be traced to this cause, notwithstanding the enormous quantity of bad meat offered for sale, including a large amount of stale and offensive fish with which the poorer classes are supplied. Nor is it difficult to account for the comparative innocuousness of meat derived from animals affected with certain diseases, considering that the parts of the animal not implicated in the local disease may be little or not at all affected, and that even if slightly unsound, they might be eaten with impunity by being thoroughly cooked, and in consequence of the remarkable antiseptic action of the bile upon the food in its passage through the alimentary canal. This antiseptic power of the bile is very great, and has been proved by numerous experiments. It has been shown by MM. Tiedemann, Gruelin, and Hoffman that when the bile was prevented from passing into the alimentary canal the contents of the latter were more fœtid than usual; and it has also been shown that the admixture of bile with fermenting substances checks the process of fermentation. In fact, were it not for some such provision of Nature, in combination with the large amount of exercise in the open air taken by the working population of the globe, we should be surprised that such a diet as that of the Färoese, for instance, and the large consumption of inferior meat by the working classes in this country, are not attended by more serious consequences than actually result from the eating of so much unwholesome food. The Färoese islanders live during a large portion of the year upon meat in an incipient state of decomposition, and introduce (says Dr. Carpenter) *rast*, or half-decayed maggotty flesh, fowl, or fish as a special relish at the end of a meal. And yet, although it has been shown that such a diet is attended with serious consequences in the event of any epidemic appearing among these islanders, the rate of mortality among them is very low. Besides, it could not be expected that the habital consumption of such disgusting food would be attended with impunity, and probably the consequences would be more serious did they not live in a very cold climate, and lead an active life in the open air.

We make these remarks to show that perhaps a distinction should be made between the flesh of an animal killed in the *incipient* stage of such a disease as pleuro-pneumonia, and that of an animal that has died from, or that has only been killed at a far advanced stage of that disease; and surely it is competent upon our veterinary and sanitary authorities to decide, once for all, whether in the former case the meat may not be sold as wholesome food, as food which, though not of the best quality, is positively harmless, and which may therefore be sold at a reduced price to the advantage of the poorer classes. At the same time it would be very hazardous, under the present defective regulations respecting the sale and slaughtering of animals for food, to allow such doctrines as those above-mentioned to be published among all the purveyors of meat in this country. Even were it proved that under certain conditions the flesh of animals that have suffered from certain diseases may be eaten with impunity, it would still be incumbent upon the State to see that those "certain conditions" should be strictly complied with, which would be simply impossible unless public slaughter-houses were established, and the animals were inspected before and after slaughter by experts appointed for the purpose, and receiving such a salary as would induce them to perform their duties in a thorough and conscientious manner. Whether such officers should be taken from the members of the medical or from those of the veterinary profession is not a question into which we can now enter. There are obvious reasons why those who have most to do with animals, both in a healthy and diseased state, should be the best judges of their fitness or unfitness for food. But whichever plan is determined upon, and whatever may be the measures adopted by Government to check the sale of unwholesome meat, it is to be hoped that something will soon be done in this direction, and for the sake of the poor, with such discretion as not to put a greater premium upon animal food than that which now exists.

THE DEFEAT OF THE COUNTER-PRESCRIBERS.

THE campaign of the Medical Alliance Association against the counter-prescribing druggists is, we are gratified to observe, likely to result in an unmistakeable victory for the doctors, and already the counter-prescribers have sustained a heavy blow which we trust may be but the prelude to their capitulation.

The case of the Apothecaries' Company *v.* Wiggins was tried on the 23rd of last month before Mr. Justice Field, it being an action instituted nominally by the Apothecaries' Society, but really by the Medical Alliance Association against the defendant, a druggist, for having acted as an apothecary in the advising and prescribing for patients. Both sides were represented by eminent Queen's Counsel, and the arguments and evidence occupy the entire of the *Pharmaceutical Journal* for the 1st of June. It was admitted by Mr. Wiggins that he compounded and sold the medicines in question, and the issue to be tried was whether he confined himself to "the buying, preparing, compounding, dispensing, and vending of drugs, medicines and medicinable compounds" as he was entitled by the Act to do, or whether he went further, and consulted with, advised, and prescribed for the patients. That he did so advise was conclusively proved in evidence, it being sworn that he cross-questioned the patient, felt the pulse, examined the tongue, and stated his opinion and advice freely. It was also pleaded for the defence that the Act of Parliament authorises all druggists to "use, exercise, and carry on the same trade or business in such manner as the same trade or business was used, exercised, or carried on by chemists and druggists before the passing of this Act," and voluminous evidence was produced with the object of showing that what the defendant Wiggins did was the custom of the trade at the time when these words became law, in which case, of course, the same proceedings might legally be continued. Mr. Justice Field laid down the law at great length in his summing up, in the cause of which he said:—

I have before me the definition of an apothecary, as I find it laid down by those who have gone before me. "I should tell you that the duty of an apothecary is that he is a person who professes to judge of internal disease," (but internal here merely means as distinguished from surgical, it is not intended to mean one particular part of the body) to distinguish ailments such as fevers; it would be difficult to find one word which expresses it all, but you know the meaning of that, "to judge of internal disease by its symptoms, and applies himself to cure the disease by medicines." That is the definition laid down by a very learned judge, Mr. Justice Cresswell, in a case he left to the jury as far back as 1845, and I adopt that and tell you that is the law. I take his language, adopt that language, and tell you that a person practises as an apothecary, if he does what Mr. Justice Cresswell here says: If he professes to judge of internal disease by its symptoms, and applies himself to cure that disease by medicines. I should ask you to keep that definition in your minds when I come to read you the evidence, and to see whether or not, what the defendant did here falls within that. Then I find another definition some years before, in which the learned Lord Chief Justice of the Queen's Bench of that day was of opinion that a man who kept no shop, but advised patients and made up and sold to them medicines which he himself ordered, did act as an apothecary in the ordinary sense of the term, and that it made no difference if he prescribed as well as prepared the medicines; he was still acting as an apothecary.

I give you those two decisions of two very learned judges, and I adopt them as the law which I lay down to you to-day.

Eventually the learned judge left it to the jury to say: 1. Did defendant act and practise as an apothecary in advising and supplying medicines or both. 2. As to the complaints he so attended, were they complaints within the custom of the trade before the passing of the Apothecaries' Act.

On both of these issues the jury found against the counter-prescribers, and his Lordship gave judgment for the amount of the penalty (£20) and costs.

The *Pharmaceutical Journal* considers that this decision is "to be regretted by all who have the welfare of pharmacy at heart;" that "the position of the chemist and druggist has not been in any way improved by the defence that has been made, and that the trial of the case, and the discussion to which it has given rise, may prove injurious to the interests of the trade generally."

Our contemporary comforts itself with the consideration that this verdict "does not in the least call in question the right which chemists and druggists possess by the authority of the 28th section of the Apothecaries' Act." We concur in this view, and would observe that the medical profession has never disputed those rights, nor attempted to deprive the chemists and druggists of one iota of their legitimate privileges and benefits. The *Chemist and Druggist*, the Bombastes Furioso of the pharmaceutical trade, claimed as a right the perpetuation of the abuses of medical practice, which the carelessness of medical men had allowed to develop. That claim has been, in great measure, now disposed of; it may be taken as the established law that counter-prescribing in the form in which it is upheld by the Druggists' Defence Association is utterly illegal, and cannot be pursued without danger of prosecution and penalty.

We are pleased to learn from the *Chemist and Druggist* that "The Executive Committee of the Trade Association has met at Birmingham since the trial of the action—and having received the opinion of their solicitor that it would be useless to appeal, have resolved to take no further steps in that case." In fact, the representatives of counter-prescribing would seem to have arrived at the conclusion that the law is dead against them, for we find their trade organ advising them to seek protection for their prescribing trade in Parliament. The *Chemist and Druggist* says:—"In view of the observations made by Mr. Justice Field at the recent trial in the Court of Queen's Bench, it would seem to be extremely desirable that an effort should now be made to get the fair and legitimate rights of chemists and druggists recognised by the legislature."

After the experience of what Parliament will swallow afforded us by the Dental Druggists' Bill of Sir John Lubbock we can speak with no certainty, but we should be greatly surprised if the counter-prescribers would improve their position by an appeal to the House of Commons, and we suspect they are well aware of this fact.

THE loss of the ship *Loch Ard* is announced, on board which were Dr. Carmichael and Mrs. Carmichael, formerly of Mountrath, in the Queen's County, and their family, consisting of two sons and four daughters, and that only Dr. Carmichael and an apprentice were saved.

VISITING PHYSICIANS IN IRISH LUNATIC ASYLUMS.

We have many times referred to the persistent attempt made by the Inspector's Department at Dublin Castle to reduce the office of Visiting Physician to a sinecure, with the view of eventually getting rid of those officers altogether; and we have pointed out how this object has been sought to be attained by insidious alterations of a word here and there in the regulations, by which trick the contest which would inevitably have arisen out of any decisive change of rule, was avoided, and the purpose gradually, but none the less effectively, achieved.

Availing itself of the opportunity afforded by the recent sitting of the Lunacy Inquiry Commission, the Council of the Irish Medical Association has fully exposed the existence of the policy to which we have referred, and has warmly protested against it in a communication addressed to the Commissioners, which will be found *in extenso* in our supplement for May 22. The Council premises that:

"The questions respecting the duties, powers, and responsibilities of Visiting Physicians which are raised by this inquiry, are of great import to the efficiency of the lunacy system in Ireland, especially considering how vitally essential it is to maintain in full force an independent and extraneous supervision of asylums."

The Commissioners are reminded that under the first code of rules for the management of asylums, promulgated in 1843, the manager was not necessarily a medical practitioner. In 1862 it was made essential that he should be a fully qualified medical man, and he was entitled Resident Medical Superintendent. In 1870 the rules for management of asylums were revised, and again in 1874. The Council directs the attention of the Commission to the alterations of phraseology of the rules at these periods, and points out that the tendency, if not the purpose, of those alterations, and of the methods of asylum administration founded thereupon, has been steadily and surely to divest the visiting physician and the Board of Governors of that controlling and supervising power which they had previously possessed, and to concentrate in the Resident Medical Superintendent the highest and largest authority, for the exercise of which he is, practically, responsible only to the central department.

The Council then proceeds to recapitulate the alterations of the phraseology of the rules to which it refers, and it gives *seriatim* the changes effected at each period of revision; and, in proceeding to comment upon them, says:

"It will be obvious that by these alterations of rule, the Visiting Physician is divested of much of his authority in respect of the treatment of sick lunatics, and the Council is aware that the rules have been construed in many asylums, as precluding the Visiting Physician from taking official notice of inmates suffering from severe bodily illness unless when required by the Resident Medical Superintendent to do so."

The Council submit to the consideration of the Commissioners the question whether it is desirable that the medical care of lunatics in serious, possibly fatal, disease should be confided to the Resident Medical Superintendent with a purely discretionary power to seek other advice. The Council expresses its opinion that the treatment of inmates suffering from bodily disease, and the management of epidemics within the institution, ought in all cases, to be confided to the Visiting Physician, and that it should be declared to be the duty of the Resident Medical Superintendent to report such cases to the Visiting Physician on their occurrence.

The Council goes on to say: "Of far higher public importance, however, is the hindrance which the alterations of rule referred to above interpose against the supervision of the asylum by the only officer who is unconnected with its internal management, and against his communicating freely to the Governors such facts as may come to his knowledge, or his opinions respecting details of the management of the institution. It is hardly necessary for the Council to point out—respecting the visitation of the asylum by an officer whose duties are under the complete control of the Resident Medical Superintendent—who is only permitted to visit at a stated hour—who is not allowed to see the patients except in presence of the Resident Medical Superintendent—who is not authorised to interfere in respect to their mental condition, except with permission of the Resident Medical Superintendent, and in case the patient is under restraint—who is doubtful as to his right to notice even their bodily condition unless 'consulted' by the Resident Medical Superintendent—and who is not permitted to state his views to his Board of Governors either personally or by report—that such a visitation can be of little value either as a safeguard for the inmates, or as a check upon possible abuses within the asylum."

While emphatically deprecating any intention to detract from either the administrative or professional repute of the Resident Medical Superintendent of District Asylums in Ireland, the Council cannot hesitate to express their decided opinion that the fullest opportunity ought to be afforded for external supervision of every asylum in which lunatics are confined, and for observation of the condition and progress of its inmates by persons outside its walls, and not concerned in its administration; and that, with this purpose, the Visiting Physician—the only continuous link between the lunatic within the asylum and the world without—ought to be restored to a position of independence in the discharge of his duties; and the Council dissents from the policy of administration of a lunatic asylum by the hands of any one officer, that officer being responsible almost solely to the central department, which cannot be fully aware of the day-to-day working of the institution.

We most warmly approve of the views expressed by the Irish Medical Association, and of the emphatic yet temperate terms in which those views are expressed. We entertain the hope that the Resident Medical Superintendents will recognise the fact that the protest is made in no spirit of hostility to them, but with a view to the preservation of a class of officers whose threatened extinction would, both from a public and a professional point of view, be greatly to be regretted. The Visiting Physicians are, indeed, in the position of the assailed, and the assault comes not only from the the central department, but from the Resident Medical Superintendents themselves; and the Irish Medical Association would fail in its duty if it hesitated to use its influence for the protection of the Visiting Physician. The profession has remained silent on the subject for many years, because, as we have said, the abolition policy has been pursued so insidiously as never to provoke serious dispute but now that it is recommended to supplant the Visiting Physician by a student resident, who will be, body and

soul, under control of the Resident Medical Superintendent, it is not too soon to record the protest to which the "Association" has given utterance.

Notes on Current Topics.

State of the Thames.

A VERY important question is just now under the consideration of the Metropolitan Board of Works. In 1875 the Board received a report from the Thames Conservancy Board on the subject of an increased deposit of mud in the bed of the Thames at Halfway Reach, near the southern main drainage outfall at Crossness. The Conservators alleged that the increased deposit was due to the discharge of the metropolitan sewage at the outfall, but this allegation the Board, after making careful inquiry, was unable to admit as correct. In the meantime, in June, 1877, the Thames Conservators instructed Captain Calver, R.N., F.R.S., to make a thorough investigation of the subject, including the analysis by Drs. Letheby and Williamson of samples of the bed of the river in the vicinity of the spot above mentioned. In October Captain Calver issued his report to the effect—"That accretions have recently formed within the channel of the Thames; that a material portion of these are in the neighbourhood of the sewage outfalls, and have formed since the outfalls came into operation; that the constituents of these accretions are the same as those of the sewage, and that the latter is discharged in sufficient quantity to account for them, the character of the tidal streams in the neighbourhood of the outfalls, as to direction and force, being the effective cause of the accumulation. He further expresses the opinion that the increase of soil in Woolwich Reach and elsewhere above the outfalls has been derived from the sewage discharge, and that the operation of accretion has been effected by the superior disturbing and transporting power of the flood stream, aided by the peculiar character of the suspended material." In consequence of this report the Board of Works has been requested to protect the Thames from the sewage discharge, and to remove at once, by dredging, the mud-banks near the southern outfall, and in Woolwich Reach. The Board, however, still thinks that Captain Calver's report is little more than a restatement of charges that have been made before and disproved; but, to settle the question, the Board's engineer has received instructions to make a thorough investigation, and to report fully to the Board.

We need scarcely remark that this report will be looked forward to with great interest, for should the allegations of Captain Calver prove true, the present system of drainage into the Thames will have to be very materially altered, more particularly as the alleged evil would be one that must inevitably increase every year, until the districts near the sewage outfalls would become remarkably unhealthy. The Board has been very properly requested to consider the practicability of depriving the sewage of its solid constituents before it was discharged into the river; and until this is done, or until the sewage is carried still further out to sea, we are afraid that most of the conclusions at which Captain Calver arrived will turn out to be too true. The plan of separating out the solid constituents of the sewage and using them for agricultural purposes has so much to recommend it that no doubt the obstacles which at present surround it will be before long surmounted, and should the report of the engineer of the Metropolitan Board of Works substantiate the statement of Captain Calver, there will be a very powerful incentive to the adoption of some means by which the sewage can be deprived of its solid constituents and turned to some better account than that of polluting the river and impeding its navigation.

Silicate Paints for Sanitary Purposes.

THE profession cannot be too generally acquainted with the sanitary and economic advantages of these new paints. The basis of these paints is silex, found in a finely comminuted state on the bed of a lake in North Wales. This fine sand, when worked up and levigated for use, contains over 90 per cent. of silica. The paint is non-metallic, and non-poisonous. It covers better, and goes farther than the white lead paint; it mixes freely with colouring pigments, is impervious to damp, resists the action of heat, and is unaffected by noxious vapours. Exposed to the foulest sewer gas it remains uninjured, while the ordinary white paint is quickly discoloured; and not only does it retain its colour better, but, hardening with time, it is much more lasting. For decorative purposes, says the *Local Government Chronicle*, and also for the preservation of iron, stone, wood, or zinc—but not lead—the preparation called enamelling paint, or silicate enamel, is very valuable; and in a sanitary point of view it answers admirably for covering the walls of hospital wards, being impervious to damp, non-absorbent, and bearing any amount of washing. Another silicate preparation has still greater claims upon the attention of medical men and sanitarians, namely, the petrifying liquid or solution of silica which is said to be a real remedy for damp buildings, and appears to be an impervious and non-absorbent covering for walls, and capable of being applied by any ordinary workman or inmate of a house. As a protective covering for stone, brick, or cement, it is supplied in a colourless fluid state, ready for use. Mixed with any of the ordinary stainers, it forms a very superior distemper paint, and like the silicate oil paint, is, when dry, impermeable, lasting, and washable. It is, therefore, both from a sanitary and economic point of view, a most desirable covering for the walls of union infirmaries, cottage, and other hospitals, school-rooms, bed-rooms, kitchens, corridors, &c. It is supplied in kegs in the form of a paste, which has to be thinned with hot water to the consistence of cream, and if the directions are carefully followed, can be applied by any handy inmate. This last point appears to us a great advantage, as the housekeeper who is disposed to keep his premises clean and wholesome, need not put himself to much expense, and can be independent of the landlord or the painter. If, moreover, it be desirable to make the room cheerful in appearance, the dado may be of a darker hue, and the line of separation defined by a simple stencilled pattern. At the Silicate Paint Company's Offices, 107 Cannon Street, City, rooms may be seen very effectively treated in this way. The upper walls are painted in distemper of a sage green, and the dado in enamel paint of a deep blue, with a simple stencil pattern between.

Recent Remarks on Small-pox and Vaccination.

An article which appears in the current number of the *Nineteenth Century*, from the pen of Sir Thomas Watson, and some recent correspondence in the *Times*, are intended to draw the attention of the public to a subject in which, as a rule, it takes very little interest. Whatever means are best calculated to ward off those epidemics of small-pox by which the country has been visited, they are, in our opinion, more likely to be enforced through the exertions of the profession than through representations made in the columns of the lay press. An occasional letter in a leading newspaper may prevent the public altogether losing sight of the subject, but, with a few exceptions, it does little more. On the other hand the medical profession are in almost daily communication with every family in the kingdom, and are therefore in the best position not only to suggest, but in a great measure, to enforce, the adoption of whatever steps are best calculated to prevent an outbreak of small-pox.

With regard to Sir Thomas Watson's article, there is one point to which we would draw attention, namely, his advocacy of the Belgian method of vaccination with the view of avoiding the risk of inoculating certain loathsome diseases along with the vaccine lymph. The fear of such an accident, is, he says, by no means groundless, and he can readily sympathise with those parents who submit to be fined time after time rather than let their children undergo an operation which they think may do harm. We regret that Sir Thomas Watson has given expression to his sympathies in so public a manner, inasmuch as the opponents of compulsory vaccination will no doubt be encouraged by the opinion of so high an authority, to persist in their evasion of the law. We would not deny that the accident to which Sir Thomas Watson refers does occasionally happen, but the frequency of its occurrence has been very much exaggerated, and a long and universal experience has shown that if the lymph be carefully selected, and the operation properly performed, there is no danger of introducing anything but pure and healthy vaccine. With regard to the Belgian method, all we have to say is that there are many obstacles in the way of its being successfully carried out among a population so great as that of this metropolis. Besides, there is no evidence to show that the vaccine matter now produced is less powerful than it was in the days of Jenner. Individual idiosyncrasy, and the carelessness of the operators, are alone responsible for the occasional inefficacy of the lymph.

The two letters to the *Times* are from Dr. Domett Stone, and Dr. Ducat, respectively. The former chiefly draws attention to the subject of re-vaccination, on the importance of which we dwelt so fully more than twelve months ago, that we shall only reiterate the hopes then expressed, that every medical man will think it his duty to press upon the public the necessity of children being re-vaccinated when they have arrived at adolescence.

In the letter of Dr. Ducat we have a graphic description of the "round-about and circumlocution office" arrangements made by the authorities to meet an outbreak of small-pox. They serve to show, he remarks, that the great art of "how not to do it," still survives. A district medical officer, for example, who meets with a case of small-pox in his district should report it to the relieving officer; the relieving officer should then report the medical officer's report to the vaccination officer. It is the duty then of the vaccination officer to visit the house in which the case has occurred, and ascertain if any persons require to be vaccinated. If so, then the vaccination officer sends off his report to the public vaccinator, and the public vaccinator's duty is now to go to the infected house and vaccinate those requiring it.

Can it be wondered at, adds Dr. Ducat, that with regulations like these epidemics of small-pox so frequently recur and spread? Certainly not; and it is evident from all past experience that compulsory vaccination and prompt re-vaccination are, along with isolation, the only means of preventing outbreaks of this disease.

Victims of the Late War.

At their meeting last Friday the Stafford House Committee had placed before them some interesting statistics of the dangers which attended the heroic efforts of the surgeons who have been employed in the East. Stafford House and Lord Blantyre sent out 35; of these 13 were stricken by dangerous maladies, and 2 died. The Red Crescent employed 45, of whom 14 were invalided, and 7 died. The Red Cross furnished 14 surgeons, of whom 3 were ill, and 1 died. The Turkish Compassionate Fund employed 11 doctors, and 3 suffered from dangerous illness. Forty sisters of charity lent their aid in the work of mercy, and of these 30 were prostrated by fever, and 13 laid down their lives in their holy mission. These facts would almost suggest the propriety of only sending out those surgeons and those sisters of charity whose health and strength are likely to stand the hardships and dangers to which they are exposed. It is to be feared that many men and women with more spirit than strength are induced to go through a campaign for which they are, physically speaking, but ill-fitted, and to which they will very probably succumb.

The Centenary of Lord Brougham.

We are not aware that any preparations are being made to celebrate this event in either England or Scotland, but we are glad to hear that the late eminent and learned Lord Chancellor is not forgotten by those people among whom, in the latter part of his life, it was his habit to pass the winter season. Steps have been taken by the Mayor and other prominent citizens of Cannes, not only to hold a grand *fête* in honour of the occasion, but to erect a noble and expensive statue to his memory. The statue is to be executed in the best white marble, and it will represent the illustrious orator and law reformer as wrapped in his cloak and pointing with his finger to the soil which he has chosen for his winter residence. It will be surmounted on a suitable pedestal, on which there will be also allegorical figures representing the British Lion reposing among some olive trees, and other subjects, The whole undertaking says much for the good taste and gratitude of the people of Cannes, and it is certainly an honour which all Englishmen will duly appreciate.

Belladonna Poisoning.

A CASE of poisoning by belladonna in a male child under 4 years of age is reported in the last number of *Guy's Hospital Gazette*. Although the child swallowed but a very small quantity (two or three drops it is stated) of a liniment containing the poison, the symptoms were very alarming and characteristic. The child screamed, clenched its hands, and was seized with tremblings and convulsions. On admission the pupils were dilated, conjunctivæ injected, and face swollen. He was delirious, often screamed, put his clenched hands up to his mouth, and had frequent slight convulsive attacks. The breathing was accelerated, with sonorous inspiration and elevations of the alæ nasi. He was treated with emetics of sulphate of zinc, followed by 5 gr. doses of tannic acid every half-hour. The next day he was quite conscious, and ultimately recovered.

Statue of Claude Bernard at Lyons.

A COMMITTEE has been formed to organise a public subscription with a view of erecting a statue of Claude Bernard at Lyons (the second city in France) near which he was born. A circular has been sent out by the committee which reminds the profession that Claude Bernard, the great physiologist who has lately been honoured by France with a triumphal funeral, was born near Lyons; he never forgot his native place, but returned thither each year, to renew in the repose of the village his ardour, and his energy wasted by hard work. During his life, the humble village where he was born and to which he was so deeply attached, became to the people of Lyons almost a place of pilgrimage, where they were sure to receive, with the reception which he knew how to give his guests, encouragement and wise counsels from the learned, to the workers who were recommended to his sympathy, by their love of science and industry. Claude Bernard has thus exercised a considerable influence in the direction of medical and physiological studies among the middle classes at Lyons by whom he is remembered with the most lively gratitude. Paris, remembering its duty to this French physiologist, will shortly erect, to him, a statue in front of the college where he went through his principal studies. The Faculty of Medicine of Lyons, which owes a great deal to Claude Bernard, has itself organised a committee to raise a public subscription, the product of which is to erect a statue in the palace of the Faculty.

The Will of Mr. Bury, of Dublin.

IT will be recollected that some months ago we announced that a sum of £20,000 had been bequeathed by Mr. Bury for the purpose of founding a hospital in Dublin. It was found necessary to institute a suit to establish the will, and the trial came off last week. Testator died on the 13th of January last. The will was dated June 9th, 1877, whereby the testator left the great bulk of his property, value £20,000, to Cardinal Cullen, Mr. Theobald Purcell, Q.C., and Serjeant Sherlock M.P., for the purpose of founding a hospital in or about the neighbourhood of Dublin for the treatment of diseases; or, if his property should prove insufficient for the purpose, of adding a wing, ward, or beds to some existing Dublin hospital. These three gentlemen were appointed trustees and executors, and for their trouble were left £20 each, but Serjeant Sherlock renounced and disclaimed the trusts of the will. The testator directed that his medical attendant, Dr. Joseph William Hepburn, should be retained as consulting physician to the hospital, and that his trustees and executors should employ Mr. William Thomas Daniell as their solicitor in the management of his affairs. The will was disputed by the defendant, Mr. Barry, of Downings, county Kildare, as heir-at-law, on the usual statutable grounds—want of due execution, testamentary capacity, and knowledge and approval of the contents; and also alleging that it was obtained by undue influence exercised by Mr. Daniell, Dr. Hepburn, and Mrs. May, the testator's housekeeper, to whom was bequeathed a legacy of £100. After a trial extending over five days the jury failed to arrive at a verdict, there being, it is understood, ten jurors in favour of the will and two against it.

The Health of Dublin.

THE total mortality of the city for the week ending June 8, is rather more favourable than that of the previous week, the deaths being only 11 over the average of same week of ten years (165 against 154). This apparent improvement has reduced the death-rate to 27·3 per 1,000 of the population, which is only 6 per 1,000 above London (21·6). The change for the better in the health of the city is unhappily only apparent, for it appears that the zymotic deaths numbered as many as 59, which is 27 in excess of the average of ten years, and 19 worse than the previous week. Of these deaths 19 were from small-pox, and the admissions of variolous patients to hospital (86) were higher than those of last week. There are now under treatment in hospital 234 cases.

The Abuse of Hypodermic Injections.

A NOTE in the *Philadelphia Medical Times* draws attention to a flagrant instance of the abuse of this valuable method of administering certain remedies. A young lady suffering from a mild attack of melancholia, came under the care of Dr. Betton Massey with seven slight ulcers on each arm. In addition to these, a series of as many deep abscesses afterwards showed themselves, and extending far in between the muscles. Her physician had thought it necessary to administer repeatedly as much as lx. gr. chloral hydrate by the hypodermic method on account of a fancied inability to give it by the mouth. By a little persuasion, Dr. Massey succeeded in overcoming her repugnance to the taste; but her previous physician's rash experiment had cost the patient three months of suffering and a lifetime of scars.

Treatment of Diphtheria.

IN the *New York Medical Journal*, Dr. G. A. Van Wagenen has given an analysis of 112 cases of diphtheria which came under his own observation. With regard to the treatment of this disease he speaks very favourably of the continuous inhalation of steam, as recommended by Oertel in Ziemssen's "Cyclopædia." The vapour is to be inhaled for 15 or 20 minutes every hour. When the membrane attacked the larynx the vapour was used constantly; and in many instances where the membrane

was light, and in some where it was heavy, the deposit broke down into a suppurating mass after 12 to 24 hours. The writer is quite confident that in five of the six who recovered after membrane was deposited in the larynx, this happy result was due to a most constant and untiring use of the vapour.

Local Sewerage and Drainage.

THE Metropolitan vestries and district boards are now by Act of Parliament compelled, before constructing new sewers, to submit the plans to the Metropolitan Board of Works for approval, in order that the proposed sewers may harmonise with the general system of drainage. During the past year plans for about 36 miles of sewers, varying in size from 4 ft. by 2 ft. 9 in. in brickwork to a 9 in. pipe, were submitted to the Board, and were all carefully examined. Moreover, 427 branch sewers have, during the year, been connected with the main sewers, under the superintendence of the Board officers.

THE poor of Dolgelly, Wales, have not much to thank their Guardians for if we may judge from the report of the Local Government Board inspector, who writes, "I must again request the special attention of the guardians to the notes made by me on both my last previous visits as to the case of the children and others being left to the care of imbeciles. At present the male nurse is an 'imbecile,' and Jane Richards, also an 'imbecile' of violent temper and the mother of illegitimate children, is in charge of the children. I can only characterise such a condition of things as a disgrace to the union."

THE parents of a child who was allowed to die at Plaistow in Essex a few days since, and whose life, according to the medical evidence, might have been saved had medical aid been summoned, have been committed for trial for manslaughter. They belong to the sect known as the Peculiar People, whose creed is in case of sickness to "send for an elder, who will lay hands on the sick, anoint him with oil and pray in the name of the Lord," medical assistance being absolutely denied.

THE Hereford Infirmary and the Aberdeen Hospital for Incurables, have each received bequests of £500. The Lancaster Asylum for Idiots has received a bequest of £184. The East London Hospital for Children, £105. The Sheffield General Infirmary, and the Public Hospital, £100 each. Sir Curtis Sampson has given £105 to the Victoria Hospital for Children, Chelsea; and "A Friend" has sent £100 to St. George's Hospital, Hyde Park, all during the past week.

THE annual rates of mortality, according to the most recent weekly official returns, were: in Calcutta, 38; Bombay, 45; Madres, 42; Paris, 25; Brussels, 27; Amsterdam, 24; Rotterdam, 25; The Hague, 27; Stockholm, 27; St. Petersburgh, 58; Berlin, 33; Dresden, 26; Breslau, 33; Munich, 35; Vienna, 33; Buda-Pesth, 45; Naples, 33; Turin, 26; Alexandria, 41; and New York, 22 per 1,000 of the population.

THE mortality last week in the four principal cities of the United Kingdom was at the rate of 22 per 1,000 in London, 23 in Edinburgh, 26 in Glasgow, and 27 in Dublin. The death-rate in all the other large centres continues exceptionally low.

SMALL-POX caused 42 deaths in London last week and 19 in Dublin, not one being reported from any other part of the kingdom. The deaths from diseases of the respiratory organs were somewhat above the average last week in London, mainly due to the extreme fluctuations of the weather.

Literature.

SCIENCE AND ART OF SURGERY. (a)

THIS work has reached the seventh edition, but the improvement in the present edition far exceeds that of any former edition over those preceding it. The whole work has been carefully revised, and new and important matter has been added. The type is more pleasing and less fatiguing to the eye, and all important points are rendered prominent by clarendon type. One hundred and fifty new illustrations have been added to the text, and many of the old ones have been re-drawn. New operations, with all their difficulties and dangers, have been described in detail, a matter of considerable importance, not so much to the student as to the young surgeon who, unguided by experience, and wanting the records of carefully compared operations, is too apt to select forms of operative interference entailing unnecessarily dangerous risks.

Throughout the work the author has endeavoured to direct the student to accuracy of diagnosis, carefully detailing the signs and symptoms of resemblance and of difference between injuries and diseases which bear any similarity to each other.

We have no hesitation in stating that the seventh edition of Erichsen's Surgery is the best work on systematic surgery in the English language.

In passing through the more important chapters we find everything that is new in the subject of surgery carefully valued.

The merits of chloroform and ether, together with the other anæsthetics, are introduced in this edition, and are compared. Esmarch's bloodless operations are referred to, showing how various English surgeons have adopted methods closely touching upon, though just falling short of that for which all honour must be accorded to Esmarch. The chapter on amputations is interesting, and indeed, exhaustive. Each operation is illustrated by a diagram, and the advantages of the one over the others under variations of circumstances are explained. The modified circular amputation which is attributed to Liston is well portrayed.

It would be well if this operation were more commonly performed than is at present the case. It consists of short double cutaneous flaps dissected up somewhat higher than the angles of the incision, the rest of the operation being according to the plan known as the circular. Another useful point referred to in this chapter is the position of the cicatrix after an amputation; the two-third and one-third double flap, the longer being in front of the bone, developing the cicatrix clear of the exposed part of the stump.

The subject of *inflammation* might be further revised with advantage.

In fractures there is but little to be added. The recent improvements in appliances for fracture are explained, and among them we notice a woodcut of Hamilton's double thigh splint with cross-bar. In fractures of the femur in children it is often difficult to maintain the limb in a good position on account of the restlessness of the patient. Hamilton's splint is applied to both limbs, so that the child is unable to move, whilst at the same time it can be turned about for cleansing purposes without pain, and without any probability of displacing the fracture.

In the chapter on injuries of the head is an interesting table showing the results of contusion of the bones of the

(a) "Science and Art of Surgery." By John Eric Erichsen, F.R.S. Longmans, Green, and Co.

head without fracture. It is taken from the records of the War Department of the United States army. Of 328 cases, 55 died, 175 were disabled, and 100 recovered. The deaths were chiefly from compression of the brain by blood or pus, or from intra-cranial injuries. The complications affecting the disabled were persistent pain with vertigo, paralysis of limbs, impairment of vision from injuries to the frontal region, impairment of hearing from wounds in parietal and temporal regions, epilepsy, and insanity. With regard to the use of the trephine, the author says it may be applied for the fulfilment of one of two principles—either with the view of preventing inflammation and its consequences, or for the purpose of removing some cause of compression. The only case in which preventive trephining is practised by modern surgeons is that of punctured or starred fracture of the skull without stupor. In all other instances the object of its application is the removal of a cause of compression, or of irritation of the brain, such as depressed bone, foreign bodies either fixed in the skull or lying close under it, or pus or blood extravasated within the cranial cavity.

At page 679 commences the chapter on diseases arising from the absorption of septic matter, or the products of infective inflammation, and the chapter following is on the subject of pyæmia. It is impossible to give an abstract of these chapters; they must be read in their entirety. All surgeons are aware of the time, trouble, and thought bestowed by Professor Erichsen upon the question of causes of pyæmia and its associated disease. His ideas were put forward and discussed at the Debate on Pyæmia opened by Mr. Prescott Hewett, when President of the Clinical Society.

The essential point of his opinions is contained in the following quotation:—

"Of all causes overcrowding is undoubtedly the most frequent and the most fatal; more particularly is overcrowding of patients injurious, if there be many *suppurating* wounds under the same roof. That pyæmia is the result of the faulty hygienic conditions just alluded to, viz., want of pure air, overcrowding, and insufficient and unwholesome diet, is evident from the fact of its being rife and most destructive where those diseases prevail, as amongst the poorer classes of all large and densely-populated towns; while in the purer air of country districts, or in private practice amongst the wealthier classes, it is rarely met with. It is one of those causes of death after operations that might and ought to be prevented." In the Franco-German war, the fact, which, however, was well known to all scientific surgeons, was established beyond all possibility of a cavil, that the danger of pyæmia increased *cæteris paribus* in proportion as wounded patients were closely crowded so that the atmosphere surrounding them became contaminated by morbid exhalations from *suppurating wounds.* Indeed there is no fact better established in surgery than that pyæmia is the result of the aggregation of the wounded, and that its development may be prevented at any time by reference to the cubic space allotted to each patient. As this is diminished so the disease increases, and this *cæteris paribus* in an exact ratio.

It must, however, be added that occasionally cases occur in private practice where the operation performed is unimportant, and where every surrounding condition is such as would be desired by the surgeon. In these cases it must be said that the constitutions of the patients are peculiarly deteriorated; there is then a tendency to develop sub-acute inflammation, or perhaps it may be more in accordance with pathological reasoning to say that any inflammation, either extrinsic or intrinsic, once established, tends by some means, possibly by embola, to bring about inflammation in other parts of the body. The healthy body is capable of combating the disease, the darts cast by the primary disease fall harmlessly among the healthy tissues, but in the deteriorated constitution each one takes effect, and pyæmia or some one of its associated diseases is the inevitable result.

The results of experiments in lower animals accord with such a view, for the injection of fluids derived from a part in state of acute inflammation into the blood of an animal, bring about effects similar to the forms of pyæmia or septicæmia in man. As Professor Erichsen says, "every stage may be produced at will between the cases of the most malignant blood poisoning and the mildest febrile disturbance by varying the nature of the fluid and the conditions of the experiment." The effects will vary with the quantity of the fluid injected, and to an extent with the condition of the animal experimented upon; but should the animal escape the acute fever, the chronic effects produced are identical in every way with tuberculosis.

Tumours.—The classification of tumours is completely altered, the German views being accepted *in toto.*

The tumours and pathological subjects, the author tells us, were illustrated by Mr. Rickman Godlee. The illustrations are numerous, very true, and well executed and form a valuable addition to the work.

It is only in recent years that this subject has received the attention of pathologists, and it is to be regretted that the different museums attached to the London schools of medicine are even at the present time crowded with specimens of tumours labelled according to the fancy of a curator at a time when our knowledge of the structure of tumours was on a par with our present knowledge of the structure of the heavenly bodies.

Under the head of tumours, is a lengthy and instructive disquisition on the origin of cancer. The author does not venture his own opinion upon a most important, though yet doubtful, question, but he appears to lean to the theory of the local origin of cancer, a theory with which we concur. There are some able surgeons and pathologists who do not doubt that cancer is of a constitutional origin; and one whose opinion on any and every subject we are bound to receive with respect, Sir James Paget, has expressed the opinion that the local disease is but a manifestation of a specific and morbid state of the blood descending from parentage, and that though many cases of cancer occur in persons among whose blood-relations the disease has never exhibited itself, yet in such cases, if the relatives had achieved a certain age, the disease would have undoubtedly appeared.

If such opinion is of grave weight, it is a very painful matter for reflection to those whose relatives near or far have been the subject of cancer or malignant growths, and it imparts a sense of self gratification to be able to comfort a multitude of minds with a strong conviction, such as expressed by Velpeau, Virchow, De Morgan, and ourselves, that this scourge of disease is but a local disease primarily, and therefore not being constitutional, cannot be greatly influenced by heredity.

(To be continued.)

THE PROGRESS OF THE DUKE OF RICHMOND'S BILL.

THE amendment introduced into the Duke of Richmond's Bill at the instance of the Marquis of Ripon, the effect of which would be to entitle the examinees of a Conjoint Board to be placed upon the Medical Register without having obtained any degree or diploma whatever, has, as we anticipated it would, evolved a most determined and active opposition on the part of the licensing bodies, especially of the corporations, which institutions, having no other sources of income than diploma fees, would be actually extinguished if this proviso became law. The English bodies are, no doubt, satisfied to think that their interests are not seriously threatened, inasmuch as the English Conjoint Scheme is (by the 14th clause of the Bill) recognised and made law, subject to the approval of the Privy Council. This approval is, however, in respect of the fee question, by no means assured, and the English licensing bodies, therefore, cannot be free of apprehension that the thirty guinea conjoint examination fee named in their scheme might yet be reduced to a nominal sum, at the instance of those who do not see why a licensing corporation should be maintained at all, or why the student should pay for his examination anything more than its bare cost.

The Scotch Bodies are, as might be expected, united in their desire to upset the Bill, *per fas aut nefas.* Their objection runs against conjoint examination in any form, and against enforced uniformity of education, and of fee; and

as it is the chief object of the Bill to secure these principles, the Scotch medical authorities are antagonistic to its progress, no matter how it may be amended in detail. They will, therefore, probably join, *vaut de mieux*, in the proposal of the British Medical Association, to remit the whole question to the limbo of a Select Committee, hoping, no doubt, that a change of government, or some unlooked-for dispensation of Providence, may interpose to prevent the enactment of conjoint examination.

The Irish Bodies, on the other hand, are warm in their desire for compulsory conjoint examination, as provided by the Bill, but, nevertheless, earnest and uncompromising in their determination to resist the Bill by every means, if the Marquis of Ripon's amendment be not modified in such manner as to admit of the continued efficiency of the Corporations.

The majority of the Irish Licensing Bodies had, it will be remembered, actually agreed upon a Conjoint Examination Scheme, which received the approval of the Medical Council; and that Scheme would, probably have been in working for the last three years, but for the refusal of the Queen's University to co-operate, and the obvious imprudence of leaving that institution free to dispose of its degrees on terms far beneath those which bound the other bodies together for conjoint examination. If the Duke's Bill had remained as it originally stood, it would have met rather with support than opposition on the part of the Irish bodies, and, we believe, we state accurately the policy of the whole of those bodies (saving the Queen's University) when we say broadly that they would desire to see the Duke's Bill made law, but will obstruct it with all their energy in the absence of a defined assurance as to the question of diplomas and diploma fees.

We understand that the Royal Colleges of Physicians and of Surgeons in Ireland have taken steps which show that they are quite in earnest. They have both petitioned for amendment of the measure, and after special consideration of the matter, have deputed representatives to act for them in London, and in the House of Commons for the furtherance of this object. The Irish College of Physicians has adopted as its programme, *a*. Direct representation; *b*. abrogation of Lord Ripon's amendment; *c*. Reference to a Select Committee if found desirable.

The Deputation named to act on behalf of the College consists of the President, Dr. Gordon, the Vice-President, Dr. Lyons, with Dr. Finney, Dr. J. W. Moore and Dr. Grimshaw, if he be able to accompany them. The Royal College of Surgeons has, in its petition intimated its readiness to aid the principal object of the Bill by co-operating in Conjoint examination, but asks generally for such amendments as may secure the continued efficiency of the Licensing Corporations. The Deputation named on behalf of the College consists of the President, Dr. Smyly, the Vice-President, Dr. Mapother, the representative of the College, Dr. Macnamara, and with them, Dr. Jacob. These gentlemen are now in London and in conference with the representatives of other licensing bodies and with members of Parliament. The medical question will probably receive some definite settlement within the coming week. Dr. Lush's Bill is set down for its second reading for this (Wednesday) evening, Mr. Arthur Mills's (the Bill of the British Medical Association) for Friday, and the Duke's Bill, we believe, will probably be considered on Monday.

Obituary.

DR. PENTLAND, KELLS.

LAST week all that was mortal of Dr. Henry Pentland was interred in the churchyard of Kells. The deceased gentleman resided in Kells for a period of close on half a century. He died on Friday week in the house where, 76 years ago, he was born. He thus lived through an eventful period in his country's history. Nearly fifty years ago he attended Lord Oriel, better known as John Foster, the last Speaker of the Irish House of Commons, in the illness which eventually proved fatal to him. Later on he watched the dying couch of the famous Irish musician, Stevenson. It is, however, of his services to the poor of Kells we would principally speak. In the dreadful years of the cholera, fever, and famine, Kells suffered most severely. Grass grew in the streets, all business was suspended, whole families died in a single day, and panic was universal. In this trying time Dr. Pentland was physician to the fever hospital. Night and day cases came pouring in, until at last even the short quarter of a mile between his residence and the hospital became too long a distance to traverse at night when instant succour to the agonising or the dying was imperative. Determined to do his duty thoroughly he had his bed removed to the fever hospital, and there day and night for over two months he lived and laboured, breathing the death-laden atmosphere, exhausted with fatigue and watching, and risking his life every hour. He finally caught fever himself, and with difficulty recovered. Such self-denying heroism as this should not be disregarded, and in the large concourse—in which all ranks and classes were fully represented—which surrounded those who bore him to his last resting-place on Tuesday, a very general wish was expressed that some steps should be taken to erect a memorial over his grave with a suitable inscription.

Medical News.

Royal College of Surgeons of England.—The following members, having passed the final examination for the Fellowship at the recent meeting of the Court, were duly admitted Fellows of the College on June 13th:—

Boulter, H. B., L.R.C.P.Lon., Hull.
Brockman, E. F., L.R.C.P.Lond., Kensington.
Cross, F. R., Redland, Bristol.
Edwards, F. S., L.R.C.P.Lond., St. Mark's Hospital.
Firth, C., M.B.Lond., St. Giles, Norwich.
Frost, W. A., L.R.C.P.Lond., Ladbroke Square, W.
Hames, G. H., L.R.C.P.Lond., Leicester.
Harrison, C. E., M.B.Lond., Chelsea Barracks.
Manders, H., L.S.A., Marlborough, Wilts.
Mercier, C. A., Salford, Manchester.
Paul, F. T., L.R.C.P.Lond., Liverpool.
Pughe, R. N. A. J., M.B Lond., Liverpool.
Roth, B. M. S., L.S.A., Wimpole Street, W.
Schofield, R. H. A., M.B. Oxon., Cambridge Gardens, W.
Williamson, G. E., L.S.A., North Shields.
Wright, G. A., M.B.Oxon., Millman Street, W.C.
Yeo, G. F., M.D.Dub., Albemarle Street, W.

The following gentleman have been elected without undergoing the usual examination:—

Army, E. S. D., M.R.C.S. diploma, 1840.
Houghton, J. S., M.R.C.S. diploma, 1838.
Kellock, W. B., M.R.C.S. diploma, 1843.
Mann, R. J., Wandsworth, M.R.C.S. diploma, 1840.

The Mineral Springs of Tarasp. Switzerland.—The Mineral Springs of Tarasp, though little known fifty years ago, are now amongst the best frequented of the Spas of Europe. Schœnlein was the first who drew attention to this district as one of the richest in mineral springs in Europe, and since then several English physicians have written upon them: Drs. Yeo, Lee, Sedgwick, Ker, &c., and they all agree that the magnificent Alpine scenery, amidst which Tarasp is situated, its

beautiful climate, its mild and equable temperature, and its unequalled abundance of springs, render it one of the most attractive and certainly one of the most efficacious health-resorts, since there are no more powerful alcalo-springs to be found anywhere. There are two classes of waters here: The Alcaline Saline Springs, to which the place owes its principal reputation, and the acidulous Chalybeate Springs which are very numerous. The St. Bonifacius Spring has been hitherto the only one used for drinking purposes, but now the Wyh and the Suotsass Springs, situate in the immediate neighbourhood of the village of Schuls, have also been enclosed and provided with spacious, handsome spa-buildings, and in order to use the aforesaid acidulous chalybeate waters for bathing also, a commodious building has just been finished at Schuls. Some of our readers will doubtless be glad to know of a place which is not yet spoiled by the crowding of fashionable people, where they can send patients needing a complete change of climate and treatment for convalescence, and as such a desideratum seems to present itself at Tarasp, we are glad to give these brief particulars, which were kindly furnished to us by Dr. Pernisch, of Schuls.

Small-Pox in the Metropolis. — At the meeting of the Metropolitan Asylums Board on Saturday last a memorial was presented from the vestry of Paddington upon the subject of small-pox, stating that as the sanitary authorities they had endeavoured to find a site for the erection of an hospital for small-pox patients of the non-pauper class, but had wholly and entirely failed. It pointed out the absurdity of the thirty-nine local authorities of the metropolis each building its own small-pox hospital, and the want of unity that would ensue, as well as the enormous expense which would be incurred, not only in the building and furnishing, but in having to sustain thirty-nine separate staffs of officers. It urged that the proper and legitimate course would be to have the control of a small-pox hospital for patients of the non-pauper class placed under the managers of the Asylums Board as a central authority, and further suggested that the sanitary authorities of each district should pay to the managers an annual sum, duly apportioned, whether they availed themselves of accommodation for their parishioners of the non-pauper class or not. It was remarked that there was a general concurrent opinion in the views expressed in the Paddington memorial on the part of nearly all the sanitary authorities of the metropolis, and the subject was ultimately referred to a committee.

Accident to a Medical Man.—On Monday evening as Dr. Neale, dispensary medical officer at Clonaslee, was driving, his horse was frightened by a donkey and bolted. Dr. Neale was thrown from the car, and his arm was broken by the fall.

ABBEYLEIX UNION.

ASSISTANT MEDICAL OFFICER. DR. STONEY'S APPOINTMENT.

A letter was read from the Local Government Board, Dublin, expressing their sanction of the appointment of Dr. Stoney as *assistant medical officer of the workhouse*, at a salary of £40 per annum.

NOTICES TO CORRESPONDENTS.

☞ Correspondents requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber,' "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

Reading Cases.—Cloth board cases, gilt-lettered, containing 26 strings for holding each volume of the Medical Press and Circular, can now be had at either office of this Journal, price 2s. 6d. The postal regulations not allowing the Journal to be stitched, these cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

Notice to Subscribers.—Subscribers who have not already paid their subscriptions for last year are reminded that they are now due and should be sent to the publishers, who will be happy to acknowledge their receipt.

CLINICAL LECTURES ON DISEASES OF THE CHEST.

We have much pleasure in announcing that with the first number of the new volume (July 3rd) we shall commence a series of valuable unpublished lectures "On Diseases of the Chest" by the late Dr. Stokes, whose name is sufficient to command the attention of medical men throughout the civilised world. These lectures have been prepared for our columns, and will be revised in passing through the press by Dr. Stewart Woodhouse, Professor of the Institutes of Medicine in the Carmichael School, to whom our best thanks are due.

Prof. Spencer Wells will continue his lectures "On the Diagnosis and Surgical Treatment of Abdominal Tumours" at the Royal College of Surgeons, London, this day and on Friday next at 4 p.m.

The Social Science Congress.—This Association is now making the preliminary arrangements for the holding of the annual congress, which takes place at Cheltenham in the second week in October. The necessary pecuniary guarantee of £750 has been raised at Cheltenham for expenses, and the committee has been appointed. The president for the year is the Earl of Aberdeen. The departments in which papers will be read are—1. Jurisprudence and Amendment of the Law: 2. Education; 3. Health; 4. Economy and Trade; and 5. Art.

Dr. F. E. R. should read the little brochure entitled "Medical Men and Manners" in connection with Mr. Erichsen's pamphlet "On Surgical Evidence in Courts of Law."

Hospital Sunday Fund.—The Council of the Metropolitan Hospital Sunday Fund are summoned to meet this day at the Mansion House, under the presidency of the Lord Mayor, to complete the necessary arrangements for the 30th June, on which day the annual appeal on behalf of the medical charities of London of 1878 falls. Last year the Fund amounted to £25,000. At the lowest estimate, double that sum is needed to supplement the general annual incomes of hospitals and dispensaries. It is hoped and anticipated that the collection this year will be more up to the requirements of the Fund than hitherto.

Mr. James T.—The style savours very much of quackery, but is scarcely sufficiently pronounced for us to condemn in these columns.

Excelsior.—Your letter is unavoidably held over to our next.

Mr. A. B, London, is thanked for the notice of his book, but as it is totally opposed to our custom and that of all respectably-conducted journals to allow authors to review their own works, we have consigned his MS. to an oft-used receptacle, as our estimate of Mr. Thom's work might possibly differ from his own.

Unprofessional Conduct.—Our attention has been drawn to an advertisement of E. W. Alabone, M.R.C.S.Eng., who offers, through the medium of the lay press, to supply the public with a work on the cure of consumption for 12 stamps, by writing to his address, Lynton House, Mildmay Road, London, N. We herewith give the author of this unprofessional announcement, and of the book—which is doubtless a wonderful production— a gratuitous insertion in our columns, at the same time we beg to draw the attention of the college which granted his diploma thereto. Mr. Alabone dubs himself M.D. in his advertisements; as no such degree is on the Register the Medical Defence Association might perhaps take cognisance of the fact.

A. W. W. (Parsonstown).—The symptoms described by our correspondent are those of chronic gastritis, and we are inclined to agree with his medical friends in ascribing the occasional exacerbation of pain from which he suffers to neuralgia. Be the pathology of his case what it may, however, it is clear that he suffered more whenever the weather is wet and cold than at any other time, and hence he should seek some climate dry and warm, or at least dry. For in such a case, the hygrometric state of the atmosphere is of far greater importance than its temperature. Hence, if our correspondent be decided on expatriation, we would recommend him either the warm dry climate of Western Australia, perhaps the finest climate of this class in the world, or else the cold dry and bracing atmosphere of Upper Canada, and of these two we should decidedly recommend him to give the preference to Western Australia.

Irish County Infirmaries and Workhouses.—We have received a further letter from Dr. Laffan on this subject, but as we can see no advantage in instituting an invidious comparison between the surgical opportunities of these institutions. and as we consider that the statements of our correspondents on both sides have been already sufficiently explained, we think it well to close the controversy, and are, therefore, obliged to decline Dr. Laffan's letter with thanks.

The Army compared with Civil Practice.—We have received a communication on this subject in which the writer takes exception to the statement put forward by the Professors of the School of Physic in Ireland as to the educational superiority of the M.D. of a University which requires for a degree a full graduation in Arts from its Doctors of Medicine. The letter expresses a good deal of the writer's views and some of his impressions, but not a single fact or argument bearing upon the subject upon which he writes. We must remind him that the proceedings of an individual M.D., even if truly stated, cannot alter the educational level of the degree which he holds, and we take it the public will consider that a medical man who has devoted four years to the study of Arts is likely to be more highly cultivated than his neighbour.

Mr. Rendle.—We are uncertain as to the point, but will answer you definitely in our next.

Vale.—Your communication is unavoidably postponed.

Clinical Lectures.

ON CONTRACTIONS.

By S. MESSENGER BRADLEY, F.R.C.S.

Surgeon to the Manchester Royal Infirmary, and Lecturer on Practical Surgery, Owens College.

Gentlemen,—I wish to direct your attention this morning to the different varieties of contractions, and in order to render this clinical lecture as far as possible an "object" lesson I have brought before you many varieties of deformity. I shall first ask you one by one to examine the cases for yourselves, and after giving your opinion, I will proceed to make some general remarks upon the subject of contractions illustrated by the cases before us.

[The students then examined the cases.]

I have drawn up this table, gentlemen, not that I think it a perfect classification of contractions, but because its pathological basis serves my present purpose better than any other with which I am acquainted. I have here divided contractions, according to their origin, into Nervous, Muscular, Diathetic, and Traumatic, and arrange them under these heads as follows :—

Nervous	Organic ...	Talipes, whether spastic or paralytic; wry-neck; some forms of club-hand; contractions resulting from rigid atrophy.
	Dynamic...	Hysterical contractions.
Muscular		All contractions of muscles dependent solely on long retention of one position.
Diathetic	Strumous Contractions	As, *e.g.*, contraction of joints following strumous, gouty, or rheumatic inflammations.
	Gouty ,,	
	Rheumatic ,,	
		Contractions of fascia of fingers, or toes.
Traumatic...		Contractions resulting from injuries of any kind.

Taking this table as our guide, I will first refer to the cases of talipes—numerous examples of which are before you—illustrative of varus, equinus, valgus, and two excellent cases of that somewhat rare form of talipes, the hollow club-foot, or *griffe pied creux* of Duchenne. No case of calcaneus has presented itself. Now each, and all these cases of talipes, are of nervous origin, dependent upon some mischief in the medulla spinalis, or it may be in the motor area of the brain itself, the result of which is *paralysis* of certain muscles, and thence overbalancing action by their antagonists, or primarily and solely on *spastic* action of certain groups of muscles; as a matter of fact, however, the latter condition hardly, if ever, is found alone, for almost invariably some form of paralysis is the initial cause of the resulting contraction. Bearing this in mind, you will be prepared to admit, what experience has now abundantly proved, that tenotomy is not the be-all and end-all as a curative agent, which it was once represented, but rather at the best must be looked upon as the less of two evils, and certainly as a remedy never to be resorted to until proved essential to restoring the proper form of the foot. The nervous lesion, whatever and wherever it may be, is sometimes congenital, when hydrocephalus, cleft palate, &c., often give other collateral evidence of the defective development of the nervous centres, or it may manifest itself under the form of infantile paralysis, or convulsions during early childhood. I think the more carefully you examine into the history the more frequently you will trace talipes to a paralytic source—in varus to paralysis of *peroneal muscles*, in valgus to paralysis mainly of *tibialis posticus and anticus*. Such is the case even in hollow club-foot, when you would certainly be inclined to think at first sight the sole error was spastic. Not so, however, as Duchenne pointed out, the cause of deformity here is paralysis of the *inter-ossei* and of the *adductor* and *flexor brevis pollicis*. We test the accuracy of this statement by Faradising the two feet of this patient who, in the left side, presents the deformity in a much more marked manner than on the right. You perceive how different is the response to galvanism on the two sides, vigorous flexion of toes taking place on the sound side, while the muscles of the affected foot scarcely respond at all.

In this case, if Faradisation of the paralysed muscles fail to abolish the deformity, I shall stretch the peroneal nerve as it winds round the head of the fibula.(a) Here, however, as in the case of talipes, galvanism and vigorous shampooing must constitute an essential—perhaps the most essential—part of the treatment. The earlier treatment is resorted to in talipes the better, for after a time the deformity becomes so extreme, and the articular relations of the bones to one another—and even the shape of the bones themselves—so altered, that complete restoration to a normally-shaped foot is often impossible, although treatment be supplemented by the freest tenotomy.

Every case of talipes, even the slightest, must be dealt with seriously, for it seriously interferes with locomotion. As Onimus has pointed out, the individual so afflicted no longer *rolls* on his feet from one uneven surface to another, but the whole of one side, or it may be the dorsum of the foot, presses equally upon the ground, and for this reason it happens that club-footed persons, unlike sound-footed folk, walk better upon a moving soil, like sand, than upon an unyielding ground.

To this group of contractions, dependent upon organic change in the nervous centres, also belong this case of torticollis and this case of club-hand.

The case of torticollis, unlike the general run of cases of talipes, depends upon spasm directly, and not upon a paralysed state of the opposing muscle—the opposite sterno-mastoid, indeed, appears to be quite healthy and vigorous; it is true that torticollis sometimes depends upon one sterno-mastoid overbalancing the opposite unnaturally weakened one, but this is not the most usual origin.

Hence it follows that tenotomy is most commonly the best practice to adopt in the treatment of wry neck; so strong, indeed, is the spastic tendency that it frequently happens that the deformity, cured for a time, recurs on the reunion of the divided tendons. If the spinal accessory nerve were easily accessible, it would be good practice to stretch it in these cases of spastic torticollis. Of course, in the paralytic form tenotomy should not be performed, but a cure should be sought for in electricity and calisthenics.

Look now at this case of club-hand; you will at once perceive that besides the contracted limb, the old woman is suffering from another mischief of a central character. There is a rigid contraction of the flexor muscles of the forearm, with a weakened condition of the extensors. When she raises her arm you perceive a general quivering of the muscles of the arm and shoulder, her left leg, too, is very weak and stiff. In fact, she has been the victim of cerebral hæmorrhage into the motor tract of the brain, followed by contraction, the flexor muscles of the forearm are permanently and structurally shortened, and are the seats of a rigid atrophy. In this and similar cases all you can do—and you can sometimes accomplish a good deal—is to stretch the contracted tendons and keep them straight. Tenotomy does no good, and simple extension will often effect a cure. You must carefully distinguish these cases of club-hand, the result of nerve-lesion, from such deformities as this case of contracted fingers of rheumatic origin, or this, which is the result of an old accident, or this, where some of the fingers are bent because the fascia is contracted.

Similar cases of club-hand to the one I show you are met with as the result of lateral amyotrophic sclerosis, and of sclerosis in patches, and in these affections also we meet with that same curious quivering of the weak muscles when they are thrown into action. But I must leave this part of our subject to draw your attention to the important group of hysterical contractions, and you will find that accurately as hysteria mimics most diseases, she here may be said to excel herself.

(a) I subsequently exposed and stretched the peroneal nerve in this case, but, owing to structural shortening of the muscles having taken place, with imperfect success. A complete cure was eventually obtained, however, by binding the toes down upon a curved splint, releasing them from time to time for the purpose of galvanising them.

The girl before you presents us with a good example of hysterical contraction. You perceive that she is extremely lame, when she walks she places her left hand above her left knee, tightly clasping it, and so helps herself along with it as if it were a crutch. She has been in this condition for seven or eight months, and attributes it to a doubtful fall she thinks she had about a year ago. The left knee is, as you see, bent to a considerable angle, and the hamstring tendons are very tense. Now, how are we to distinguish between this and contraction due to real shortening of these muscles. Well, in the first place there neither is, nor has there been, any joint disease; often hysteria mimics true arthritis, copying all the symptoms except the heat and redness; but in this case there has not even been any mimicry of articular mischief. Now unless there has been some *bona fide* cause for a patient to bend the knee for the sake of ease, I should advise you to doubt the real nature of the contraction. If from any other cause the knee is bent for a long time, then the shortened flexors become structurally shortened, and this law is immensely important to remember in dealing with contractions of talipes or of muscles contracted by being kept in a compressed condition for a length of time, often an injury. They become, as I say, organically shortened, their fibres undergo a fatty degeneration and absorption, and the distance between origin and insertion is permanently decreased. This is true in every case except hysterical contractions; here be it that the muscles relax in sleep, or be it from other causes, it will, I think, be found that the muscles do not undergo an organic change. But to return to the case of this girl: besides this absence of a sufficient cause for the contraction, our diagnosis is aided by the lameness being quite out of proportion to the amount of contraction, and further by the age, sex, and aspect of the patient. But how are we to *prove* our diagnosis—by chloroform? Chloroform is the Ithuriel's spear which unfailingly detects the deceptions of hysteria. Let us place our patient here under the influence of an anæsthetic. Having done so, you see that it is as I predicted; without force, without anything more than a touch, the rigid muscles relax, and the crooked becomes straight. I cannot help referring to another case of hysterical contraction, though they are so numerous that it seems scarcely necessary to swell the list. Still the case was seen by many of you, and as it tells against myself, the relation has some piquancy.

Four years ago a healthy-looking girl came to the out-patient room of this hospital with aggravated talipes equino-varus of the right foot. The muscles of the leg were wasted, and the limb was blue and cold. She remained under treatment (my treatment) for some months with very little benefit, when I sent her into the hospital with the intention for performing tenotomy. The then house physician, however, for some reason or other, appeared to suspect the real nature of the case, and administered a vigorous dose of the galvanic battery, when, as if by magic, the deformity disappeared, the girl jumped on to her feet, and very literally the lame walked. She required little further treatment, and soon after joined us as a nurse, in which capacity she has remained up to the present time.

In every case of doubt I would certainly advise you to use these two admirable detective objects, galvanism and chloroform, but the greatest of these is chloroform.

I think we should perhaps place those cases of ideal contraction after a real injury under this head of hysteria, though in some important respects they differ from true hysterical contraction. Thus the patients are often men, or if women, have never exhibited any other evidence of the polarised state of the nervous system which characterises hysteria. Again, there has been a real injury, and for the relief of pain the limb has probably assumed or been intentionally placed in the faulty position. Well, here again, chloroform will solve the riddle, and often nothing but chloroform will do so. I lately saw a "bonnie fishwife" who had suffered from an acute attack of traumatic synovitis, and whose knee was almost bent to a right angle. So rigid were the hamstring muscles that I

thought adhesions had formed—it was evident from her face and manners that she was no more the subject of hysteria than Bismarck. Chloroform was therefore given, and I seized the foot with the intention of using probably considerable force to bring the limb into position, but nothing of the kind was necessary, it fell into position of its own accord, much I assure you to the surprise of myself and the gentleman with whom I saw the case.

Contractions dependent upon long Retention of Muscles in one position.—This class is represented by these two cases of rigidly contracted fingers following an injury to the the hand. They are important, because they are preventible, or rather because they should very rarely if ever occur. Sufficiently early passive motion will generally prevent this form of contraction, and they are important, again, because, as remarked above, the muscles so placed do after a time become organically shortened. Whenever met with the proper treatment, is of course, forcible straightening under chloroform, followed by vigorous shampooing.

The next group is a large one, comprising as it does all contractions dependent upon diathetic causes.

Diathetic Contractions. — We will consider seriatim strumous, gouty, and rheumatic contractions.

Strumous Contractions.—Nothing is more common than for a case of strumous arthritis to be followed by a rigid contraction and true shortening of the muscles (the flexor muscles for the most part) around the joint. This condition, it is true, resembles the contractions of muscles referred to immediately before, but the treatment differs so importantly that I purposely relegate its consideration to another heading. As in the former class, prevention is better than cure—much better, indeed, in the strumous class, for whereas, in the former, vigorous movements are indicated, and often sufficient, in the latter, *noli me tangere* may be taken as our motto. Never rashly pull about or try to straighten a contracted strumous joint. Be the disease in the joint never so thoroughly subdued, rough handling will very often rekindle the slow scrofulous fire. All you can safely attempt in this unfortunately numerous class is by patience and extreme gentleness to gradually restore the limb to its proper shape.

Rheumatic Contractions.—Turning to rheumatic contractions, the most common are, like the hands of this poor woman, cases of rheumatic arthritis. These contractions are the result of a spasmodic action of the flexor muscle of a reflex nature, as Charcot has shown in his "Cliniques sur les Maladies des Veillards," the rheumatic poison acting as the irritant. So vigorous often are the resulting contractions that luxation of of the phalanges from each other or from the metacarpal bones frequently ensues. Mournfully grotesque are the deformities which are caused in this way, and, unhappily, neither surgery or medicine have as yet availed anything in either prophylactic or curative treatment.

Gouty Contractions.—I have here two cases of contraction of the fascia of the fingers, which are possibly of a gouty origin—at least, a gouty origin is often attributed—and though, in many such cases, I admit it is difficult to trace, still, like the blue bar in the pigeon, cropping up after ever so many generations in the "pouter" or the "carrier;" if we went far enough back we might perhaps succeed in tracing them to a gouty ancestor. It is certainly a curious affection, this contraction of the fascia of fingers and toes, and often hereditary. In the one case you see the little fingers of both hands are bent to a right angle; in the other the ring finger of the left hand alone is the one affected. Though sometimes a slight injury may set this contraction going, such a cause is by no means necessary, or even usual. Most frequently no traceable cause, as I have said, can be assigned, so we fall back on a possible history of gout. The contraction affects the fascia alone, the tendons always remaining quite free from participation in the deformity. Tenotomy is, then, manifestly out of the question, but still an operation is required. This consists in dissecting off the skin and dividing the constricting and contracted bands of fascia. When this is done the finger or toe is at once loosed from its bonds, and becomes quite straight. In operating freely divide all such bands rather than burst them, as by the latter procedure you may tear the skin, and so give rise to ulterior and obstinate contraction.

Those cases of contraction of joints, contraction of the flexor groups of muscles, resulting from long retention of one position, come under this same head of "Diathetic Contraction." They are pre-eminently the cases which bone-setters cure—at least, that is to say, some of them. If a healthy man has had an attack of synovitis, with subsequent lameness and stiffnesss from contraction, then the rough manipulation of the bone-setter, by which he puts the imaginary bone, which was out of its imaginary joint, into its place, will often loose him from his bonds and set him free, but woe betide that joint should it be in a strumous subject; then nothing is more sure than such rough handling will be followed by further mischief, and the last state of the patient be worse than the first. If it chance to be a contracted joint, again, in a rheumatic subject, or from rheumatic causes, sometimes good and sometimes harm will accrue from vigorous movements. A scientific decision as to whether force should be employed in these cases can only be arrived at from carefully considering each case. It may be laid down as a general rule that, so long as there are any active symptoms of inflammation, any pyrexia, any heat, or pain, or redness, no violence is admissible, and that, after all these evidences have subsided, we must be content to treat the cases according to their individual nature, and the diathetic habit of the patient. In the healthy, force used even extremely, may be practised with advantage; in the rheumatic considerable force, too, may be used, with frequent slighter exercises, to prevent re-formation of adhesions; in syphilitic and gouty cases (with caution, and the employment meanwhile of suitable internal remedies) adhesions may be broken down, and contracted muscles stretched. Whenever such means are employed it is, I think, a good plan to apply an ice bag for twenty-four hours or more to the wrenched articulation. In strumous cases, however, as I have said, nothing but ill can be expected to follow such treatment; then, if gentle exercise, such as quiet continuous extension with a weight and pulley, fail to remove the contraction, it is far better to divide the contracted tendon, or band of fascia, by subcutaneous section.

Traumatic Contractions.—It remains for me to speak of contractions following wounds and burns, of which there are several examples here. All of them are alike in this—they are extremely insidious in their progress. They do not—at least, very frequently they do not—appear at all threatening or severe, at first, but little by little they produce the most terrible deformities. Whenever and wherever skin is destroyed, the resulting cicatrix occupies a less space than the original wound. A cicatrix is like old Trapbois—"Do not trust my father," said Martha to young Nigel, "for, simple as he looks, he will take you in and ruin you"—and so with the contractions of traumatic origin, unless we are specially on our guard counteracting their evil tendency, we shall be drawn, or rather the arms, and legs, and faces of our patients, will be drawn, into all sorts of unfortunate and inconvenient positions. The habit, too, seems to be almost life-long; this habit of contracting steadily continues as if the cicatrix were a stock-broker. More will be done in the green than in the dry—that is, more good is to be effected in these cases by extreme care during reparation by stretching and constantly keeping the part stretched, than by operation afterwards. Still, when the deformity is pronounced and confirmed, much good is to be achieved by careful surgery, and few fields afford more room for ingenuity than cicatrices. Plastic surgery of every kind, slipping, grafting, sliding, &c., is to be put in practice as the case requires, and it is evident that no set rule of procedure will apply to all cases. I think, however, it should be taken as a rule, never to put the parts on the

stretch immediately after performing a plastic operation upon an old cicatrix; if you do, the cicatricial tissue left —and I am presuming that some is left behind—is sure to tear, and so, by and bye, you will find that you have had your trouble for nothing. Here, more almost than elsewhere, the best results wait upon the careful, painstaking surgeon rather than upon the brilliant operator, if he be a brilliant operator *et preterea nihil.*

Original Communications.

ON SYPHILIS AS IT AFFECTS THE BRAIN AND NERVOUS SYSTEM.

By THOMAS STRETCH-DOWSE, M.D., F.R.C.P. Edin.,

Late Physician-Superintendent to the Central London Sick Asylum, Highgate; Physician to the North London Hospital for Consumption and Diseases of the Chest.

(*Continued from page* 503.)

Syphilis of Peripheral Nerves.

It is certainly questionable if we have any reliable clinical evidence to guide us concerning syphilitic changes in the peripheral spinal nerves. We have seen that syphilitic disease of the cranial nerves is not uncommon. Dr. Barlow gave an instance in the Path. Soc.'s "Transactions," 1877, and others have been recorded by Virchow, Leon Gros, Lancereaux, and Graefe. The case recorded by Dr. Barlow, the pathology of which is given in the article on "Hereditary Syphilis," shows well the ordinary form of degeneration which is usually met with, and proves most clearly that the nerve substance may be the seat of a definite and distinct neoplasm. But it is from pressure, rather than from intrinsic inflammatory changes, that the peripheral nerves even in syphilis have been proved to undergo degeneration, or by a direct extension of the infiltration into them of gummatous inflammations. In the article of Dr. Heubner upon the subject in Ziemssen's "Cyclopædia of the Practice of Medicine," he says that the nerves may be affected in various ways under the influence of syphilis. "It may occur that the peripheral nerves or their nuclei in the central nervous substance or their roots, or the ganglia which are dispensed along their course, are altered during the existence of constitutional syphilis in such a manner, that grave functional disturbances are excited, although it has been as yet impossible to demonstrate the alterations in question by means of the knife or the microscope." I would extend this observation of Heubner, and say, that syphilis in some persons so alters the normal attributes of the spinal nerves, that their motorial vaso-motor and trophic action is so interfered with that any external exciting cause is particularly liable to suddenly or progressively arrest their function. It has never been proved satisfactorily why an injury to the shoulder in a young subject should be followed by rapid atrophy of the deltoid rhomboid and scapular muscles, whilst in another subject, under similar conditions, no such consequences ensue, and the same remark holds good in reference to writer's cramp and palsies of the thenar and hypothenar eminences. Without entering into the argument of central or peripheral primary molecular disturbance, I can only say that I have cured such cases by the aid of iodide of potassium and mercury, when other treatment has failed. I mean, of course, where I have sought for and found clear evidence of syphilis.

Dr. Brown-Séquard remarks (*Archives Scientific and Practical Medicine*, New York, Jan. 1873): How quickly atrophy may appear in muscles of which the nerves have not been injured, and through an influence exerted by neighbouring nerves.

As far as the peripheral spinal, no less than the cranial nerves are concerned, whenever in fact there is an arrest of function, I make myself as sure as it is possible by clinical evidence to do, that syphilis is not mixed up with it.

If a patient presented himself with an internal squint, and diplopia or ptosis with a dilated pupil, and an external squint or a partial or complete palsy of the facial nerve, which came on gradually without other cranial or spinal nerves being involved, our first idea would be that we had syphilis to deal with, and I am quite sure of this, that the surgeon would be amply repaid if in the muscular and nerve degenerations resulting from injury, he made himself certain whether or not he had to do with a syphilitic constitution. Mr. Erichsen in his admirable work on Concussion of the Spine, dismisses the question as to the part played by constitutional syphilis in producing nervous disorder after railway and other accidents in a very summary manner, and I am quite sure that the subject is deserving of much more attention than he seems inclined to give it. He says, "that the paralysis of a syphilitic patient may be traumatic, and not in any way dependent upon a syphilitic taint. Thus the ptosis, strabismus, and double vision, which are so common in the syphilitic forms of brain disease, are very rare after spinal concussion." One can easily understand why a palsy of the third nerve should not necessarily follow a concussion of the spine, although it may produce extreme sympathetic depression, but I maintain that it is impossible for a syphilitic patient to receive an injury to the nervous system, either central or peripheral, without the constitutional taint playing its own part (and an important one too) in the course of, or it may be the extension of, the disease.

In Dr. Mitchell's most excellent volume "On Injuries of Nerves and their Consequences," I have failed to find that this important element has been taken into consideration, but in speaking of trophic nerves, the idea must have suggested itself to him, for he says, "we can only conclude from these facts," referring to the power of repair in tissue, "that a certain individuality of cell life controls the results, and that the cell life of one man so differs from that of another as thus to present us with varied phenomena under what seems to be equality of conditions." If there be no objective signs of syphilis, we have little to guide us beyond the patient's history, and our discriminating powers of observations. If there be a neuritis in the course of a mixed nerve causing atrophy of its substance, and of the muscles which it supplies, then there will be loss of the electric irritability and co-existent want of electro-muscular contractility. But it must be clearly seen that this is no test of syphilis, but merely indicates loss of the conducting power between the peripheral twigs and ganglionic centres. In disease of the anterior horns of the spinal cord, with resulting muscular atrophy, and in a hemiplegia from central disease, we know that electro-muscular contractility is rarely interfered with, and I cannot for my own part see in what way we are aided in our diagnosis, provided we find that only an isolated nerve, and its supply, is cut off from the main branch, or its point of origin; but if under anti-syphilitic treatment the function is restored, and if in a short time from some depressing cause its neighbour is similarly influenced, then in all probability we shall have good reason for believing that syphilis is present. The nocturnal character of the pain in syphilis of the cerebral nerves is a marked feature, and the same condition exists but to a limited extent in neuralgias of the spinal peripheral nerves. The following case is instructive in this respect.

Case XXIV.—*Syphilitic changes at the Base of the Brain, involving especially the Optic Nerve and Gasserian Ganglion.*

W. E., æt. 62, came under my care on the 10th June, 1876. He was of temperate habits, but contracted syphilis when he was thirty-seven years of age, and suffered

severely from it for years. Of late he has suffered from flying rheumatic pains in the muscles and joints. About seven years ago he lost the sight of the *left* eye. He knew nothing about it until he closed the *right* eye and found that the sight of the *left* had gone. At this time there was no affection of the face, like that which he now has. In the month of January, 1876, he got up at his usual time in the morning, and the wind was blowing very cold from the east, when he suddenly experienced a sensation over the *left* half of the face, as though a number of pins and needles were pricking it. In a few minutes he became so giddy that he was scarcely able to support himself. He lost neither consciousness or voluntary power. On the following day when he put the *right* hand into *hot* water it felt cold, and for the past six months when he washes the *left* side of the face with *cold* water it burns and gives him intolerable pain.

There is a *constant* feeling over the *left* side of the face, as though pins and needles were pricking it, but this is varied by sensations of a most unpleasant character. Sometimes it feels as though a red-hot iron was being pressed against the skin, at other times, as though boiling water were being poured over it, or hailstones were being driven against it, or that innumerable flies were tickling the left side of the nose. These strange sensations were a source of great trouble to him.

When I first saw him he looked careworn, and without questioning, it was apparent that his sight was imperfect. There was no objective paralysis. Upon ophthalmoscopic examination, there was found white atrophy of the *left* disc, and advancing atrophy of the *right*, the line of separation between the preserved and obscured halves of the field of vision was vertical. The vision of the left eye was gone.

The urine was free from albumen and sugar, and of normal gravity.

Cranial Nerves.—1st, Defective on the left side; 2nd, as noted; 3rd and 4th, normal; 5th, normal on the right side. On the left there is marked synæthesia, variations, and abnormalities, uncommon sensation, as noted, and slight decrease of electro-muscular contractility in the muscles supplied by the third division of the 5th on this side. At times he complains of stiffness about the muscles in mastication. 6th and 7th, normal; 8th, the taste on the *right* side of the mouth has always been natural, but on the *left*, he says it seems as though he had strong cheese or pepper there. There is constant accumulation of saliva in the mouth; no dysphagia or dysphonia. The chief points in this case, which is one of exceptional interest, are the right hemiopia and the neuralgia of the sensory divisions of the left fifth nerve, and the constant aching wearying pains which are localised to the parts supplied by this nerve, greatly increasing towards night. It at once brought to my mind the words of Dr. Anstie in his Lettsomian Lectures, 1866, "On certain Painful Affections of the Fifth Nerve." He said, "supposing *it were possible* that a patient should be affected with universal and equally violent neuralgia of all the branches of the fifth nerve, the situations in which the most important of these painful spots would be developed are—1st, the parietal; 2nd, the supra-orbital; 3rd, the trochlear; 4th, the palpebral; 5th, the ocular; 6th, the nasal; 7th, the infra orbital; 8th, the malar; 9th, the superior labial; 10th, the mental; 11th, the auriculo-temporal."

Now, these points alluded to by Dr. Anstie were all more or less influenced in this patient, and he improved very considerably under the use of anti-syphilitic treatment, when other remedies had no influence whatever upon him.

CASE XXV.—*Neuralgia of the Sciatic Nerve—Atrophy of Right Buttock—Neurosal and Syphilitic History—Cure.*

F. B., æt. 42, came to me in March, 1876, complaining that she had been in indifferent health for years. Her mother was subject to fits, and her father died insane. Her grandfather fell from his horse and died in a fit. Her grandmother was found dead in bed. Her nephew died in a fit at the age of 18 years.

She married at the age of 21, and contracted syphilis from her husband, and from this time her health began to fail. She has given birth to thirteen children and miscarried four times. Only five of the children are living. Three died in convulsions before they were three months old; one died in fits at 7, and the other at 16 years of age. She says that she has been subject to seizures affecting the top and back of the head, dimness of sight, twitchings about the mouth and eyes, with numbness and coldness about the extremities.

The uterine and ovarian functions were normal, the bowels acted regularly. She said that for eighteen months before she consulted me she had been suffering severely from pain of the right hip running down the back of the leg; it was always very much worse at night after going to bed; at times the limb felt numb and cold, and then again the prickings and shootings were indescribable. She stated that the doctors told her she was nervous, and that when she got strong the pains would go away. I was inclined at first to look upon it as hysterical, but upon examining the limb I found such marked atrophy of the muscles and integument of the buttock with diminished cutaneous and electro-muscular contractility, that I concluded there must be some pressure upon, or chronic interstitial inflammatory change in the nerve itself. I satisfied myself, as far as I could, that the disease existed rather without than within the pelvis, and there were no signs indicative of hip-joint disease. At times the muscular cramps were persistent and intolerable, and the movement of the limb gave her intense pain. Upon making pressure between the trochanter major and tuberosity of the ischium and just a little below the pyriformis muscle it gave her excruciating pain. I treated the case as a chronic syphilitic neuritis, first, with leechings and hot chloral solutions to the seat of pain, after this flying blisters were had recourse to; and lastly, the induced galvanic current soon altered the condition of the atrophied muscles. Anti-syphilitic remedies were administered, and in two months she was quite well.

I quote these two cases, as I could a large number of others, to show how difficult it sometimes must be to make a correct diagnosis in cases of peripheral nerve lesion, and how much more difficult it is to diagnose a specific from a common neurosis. But I should say never attempt the excision of a nerve until syphilitic remedies have been exhaustively tried.

(*To be continued.*)

THE INNER LIFE AND ECONOMY OF A LOCK HOSPITAL IN INDIA. (*a*)

By SURGEON-MAJOR W. CURRAN,
Army Medical Department.

(*Continued from page* 504.)

THE uterus itself is, as I have already observed, very little altered or affected by the irritation to which it is subjected, in these women; judged by an ordinary female sound—for I have not Simpson's instrument by me—its calibre is, for the most part, unchanged: the cervix is, however, sometimes, though rarely, elongated, and I have noticed a tendency towards prolapse in two or three of the older women, the walls of the vagina also bulge out sometimes, and the orifice of the meatus urinarius is often red and pouting. The clitoris is, strange to say, almost as free from the appearance of irritative change as is the uterus, but it is enlarged or actually hypertrophied in a few instances, chiefly among the older women, and I have had no reason to suspect the influence of any other form

(*a*) It may be necessary to explain, for the benefit of those who do not understand Hindoostani, that the word "purka" means, in reference to a well, wall, or building, masonry, as distinguished from clay; while the words "dhai," "chowkedar," and "bhistie," mean respectively a nurse, a watchman, and a water-carrier.

of abuse or indulgence among any of them. I infer, as well from these appearances as from their own acknowledgements, that the sexual act is, with most of these women, more a matter of mere mechanical compliance, for filthy lucre's sake, with the requirements of their situation, than one of excitement or passion, the erotic element seems, in short, to be, with most of them, in abeyance in the business.

Touching the os and its belongings, not much has been said, for the best of all reasons, that there is little to say about either, and the absence of structural change here, as elsewhere, seems to be their prevailing characteristic. It is, as we might expect, generally enlarged throughout, or elongated laterally in those who have borne children, but this is not always so, and there are several women in my *clinique*, in whose os, impregnations can scarcely be said to have produced any change at all. I have noticed a very similar enlargement or prominence in some of the older women, who have never borne children, or even conceived, and there is often such a narrowing of this aperture in others, as scarcely admits of the entrance of a probe. This narrowing does not, however, appear to interfere with the menstrual flux, and as regards the condition, which I have ventured to call *faute de mieux*. Nævus of the os is very rare, so rare, indeed, is it, that I have only seen two or three typical cases in all the women who have passed through my hands during the last year. There are, however, four or five others in whom it exists to a lesser degree, but it is more dependent, in these, on a better developed after-menstruation than it is in the instance just referred to, and yet is it permanent in all? It occurs exclusively on the lower lip, and is characterised by a diffused pale pinkness, or a deep reddish—according to period—hue, and the vessels that pervade it are usually so enlarged or reticulated, as to resemble the appearances produced by an arrest or irritation of the circulation in the web of the frog's foot. In one instance, only, have I seen it as a corona surrounding the os, and in this instance its vessels converged, like the spokes of a wheel, towards that opening, or were lost within the cervix. To simplify the matter and carry out my old programme to the end, I will subjoin a table, in which my estimate of the appearances so imperfectly set forth above, will be included, and my reasons for regarding this condition as akin to, if not absolutely identical with nævus, will appear under the heading of "Remarks."

Finally, having made, through my native subordinate, some experiments on the temperature of these women, and I need scarcely point out how suited they are for such a purpose, I subjoin the general results, and simply adding that I cannot vouch for their accuracy, I leave them to speak for themselves. The observations were taken by means of one self-registering and one plain thermometer, which may account for their variation, and I am, I regret to say, precluded by other engagements, from verifying or enlarging them. Out of the fifteen cases subjected to examination the temperature averaged 97·26 in the axilla, while it only reached 92·13 in the mouth. It reached 96·8 as an average in the anus, and 99·13 in the vagina, and there was no febrile disease amongst them at the time. I had hoped to be able to present some microscopic illustrations of the vaginal and other secretions of these women, but "non sum qualiseram bonæ sub regno curæ." Fifteen years of almost continuous service in the tropics, has robbed me of much of the suppleness and elasticity I formerly possessed, and zeal or enthusiasm would appear to be thrown away in a department which takes no cognisance of such voluntary efforts on the part of its members, and metes out its rewards according to the laws of longevity, or at the request of friends. I thought it a pity, however, to lose an opportunity that may never occur again, and if a man cannot bring himself to undertake inquiries of this kind for their own sake, he had better not undertake them at all. That was the view I took of the situation from the beginning, that was the view that induced me to wade through such a mass of falsehood and filth, and that is the view that now enables me to bring this, my review of it, to a close. Though presenting, possibly, many traces of hasty generalisation or incongruous grouping; nevertheless, is it substantially a true one, and I can freely say, that I spared no pains upon it. I have, however, no books to refer to for guidance or reproof. The season and the situation are alike unfavourable for minute investigation or protracted research, and I must plead for indulgence accordingly. The subject is, moreover, neither pleasant nor inviting, and any or such crudeness or boldness as may appear to characterise my treatment of it, should, in fairness, be ascribed, not to a want of care or thoughtfulness on my part, but to those effects of climate or errors of constitution, which no man may hope to entirely surmount or control.

TABLE No. 10 *shows the Appearances Exhibited by the Cervix in 85 Native Prostitutes; as well as of the Os, in its Relation to Nævoid Pigmentation, or Vascularity.*

No. examined.	Appearances of the cervix.				Nævus of the os.		Other features of this inspection, as well as of these parts.	Remarks.
	Healthy	Abnormally vascular.	Ulcerated. Merely abraded	Ulcerated. Honeycombed	Perfect.	Imperfect.		
85	39	8	9	6	A perfect nævus occurred in 2 to 3 instances during the year in all the women I have examined.	An imperfect one occurred in 3 to 5 instances within the same period.	The os was reduced in size in 10 of these women, and 5 of them were found to be menstruating naturally. One had a wart growing from its side; and there were only 3 admissions—2 for leucorrhœa, and 1 for abrasion. By the term "honey-combed," I understand an aggravated condition of ulceration, which only exists among the older women, and which sometimes suggests an actual agglutination of the opposing surfaces. It is very intractable to treatment, though apparently incapable of spreading infection; and the women in whom it exists appear to be beyond child-bearing.	If it be true, as laid down in Lane's edition of Cooper's "Dictionary," vol. i., pp. 318-19, that "nævi comprehend all the stains, spots, and deviations of a part of the skin from its normal state, which are congenital," or, that "some of them are merely superficial or stain-like spots, which are most commonly of a purplish-red colour of varying degrees of intensity, such as the presence of a considerable collection of blood-vessels situated near the surface and covered with a thin cuticle, naturally occasions," then is this term applicable to the condition noted within, and the increased turgescence and vascularity that menstruation imparts to the lip on which it is situated (always the lower) lends additional support to this assumption. Anyhow, such is my belief; and were we able to inspect the parts we would, I think, find, on removing their surroundings, that (Todd's "Cyclopædia," vol. i., p. 243) it consisted "of a series of vessels, arranged in a uniform manner, dilated at some points and contracted at others." Whether this condition has yet been described in books or not I am just now unable to say, but of its existence I have no doubt at all; and there is no reason that I can see why it should be peculiar to the Indian prostitute.

Clinical Records.

SOUTH LONDON OPHTHALMIC HOSPITAL.

Under the care of Mr. SPENCER WATSON.

Cases of Glaucoma.

CASE I.—*Traumatic Glaucoma.—Iridectomy.—Recovery with useful Vision.* (Date of operation, Nov. 19th, 1872.)

An engineer, of about 28 years of age, was struck in the eye by a chip of cold iron. When seen a fortnight after the accident the cornea was abraded, the globe tense and congested, sight so imperfect that he could only just count fingers, pupil dilated, and constant pain in brow and temple preventing sleep. A small iridectomy was made upwards and inwards. A week after all the symptoms had disappeared, but the sight had only so far improved that he was able to read No. 19 of Jæger's text-types.

Remarks.—The noteworthy feature of this case was the age of the patient. Very few cases are recorded of glaucoma below the age of 30, and it is possible that in this case there was some deep-seated ophthalmitis set up by the injury which gave rise to the glaucomatous condition.

CASE II.—*Double Glaucoma.—Iridectomy in both.—Result good.* (Date of operation, Oct. 3rd, 1873.)

Eliza N——, æt. 63, had suffered from glaucomatous symptoms in the right eye for two months, and in the left for two or three days. The *right eye* has T_3. V. O. *Left* T^2. V. Tells the time by the watch.

Iridectomy upwards in both eyes, a rather smaller piece of iris being removed in the right eye than in the left.

Four days after operation.—*Right eye.* Still tension, pain very severe. *Left eye.* Vision much improved, pupil clear.

Ten days after.—*Right eye.* Tension normal, less pain, and anterior chamber more formed. *Left eye.* Vision improving. Tension, no pain.

Six weeks after the operation.—*Right eye.* Slight pain occasionally. V. O. *Left eye.* V. J 16. Tension, no pain.

Remarks.—The patient in this case was suffering from asthma and bronchitis, and her general health was very defective. The results of the operation were therefore less satisfactory than in some cases, but quite as good as might have been anticipated.

CASE III.—*Chronic Glaucoma.—Iridectomy.—Success.*—(Date of operation, April 24th, 1874.)

Elizabeth Gill, æt. 74, sight failing the last two years.

Right eye. V. J 16. F. limited. Optic disc excavated. *Left eye.* V. J. 16. F. limited. Optic disc white and excavated. T. ½. Orbital and nasal pain. Chromopsiæ.

April 24th.—L. Iridectomy upwards.

May 18th.—L. Tn. V. as before. No pain, no chromopsiæ.

Remarks.—This appears a very limited amount of success as compared with the results obtained after iridectomy for acute or sub-acute glaucoma, but is more than can always be reckoned upon in the chronic form of the disease, especially if, as in this case, there happens to be incipient atrophy of the disc and great limitation of the field of vision, as well as of its acuteness. No improvement of sight was obtained, but the eye was placed in such a condition that it will not become rapidly deteriorated, and it is not exposed to the danger of a sudden acute attack.

Remarks.—In reference to the asthmatic condition of the patient, Eliza N. (case 2), I have twice since been struck by the fact of the occurrence of glaucoma either in asthmatic or emphysematous subjects. It is a fact of some significance and may possibly serve to elucidate the pathology of this disease. I am, however, unable, as well as unwilling, to form any theory on the subject without further data, the mere coincidence of the two diseases being in themselves not necessary to indicate more than the relation of predisposing cause and effect; congestion of the head and of all the cranial organs being one consequence of any form of dyspnœa, and therefore often associated with asthma and bronchitic emphysema.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, JUNE 26, 1878.

THE MEDICAL REFORM BILL AND ITS PROGRESS.

THE past week has been, as we anticipated, marked by the most energetic action on the part of the profession in view of the alarming crisis in which the Duke of Richmond's Bill has placed its affairs. The unexpected, and, we may add, injudicious, introduction of Lord Ripon's amendment, by which all diplomas were rendered supererogatory, has evoked amongst the qualifying bodies an agitation hitherto unfelt, and has given birth to a discussion of medico-educational affairs, which, of itself, cannot but be of much value to a future understanding of the subject. As we stated last week, the Irish and Scotch Colleges of Physicians and Surgeons had lost not a moment in considering anxiously the position in which the amendment placed the licensing bodies, and—being to all intents in accord as to the effect of that enactment—had sent their highest responsible officers with other delegates to London to represent their views to Government, to Parliament, and to representatives of the English qualifying bodies. We are gratified to understand that the result of the conferences held with ministers, members of parliament, and the leaders in the profession in London, has been eminently satisfactory, inasmuch as such interchange of views has shown that the feelings and interests of the Irish licensing bodies are, in great measure, in accord with the influential views of the English licensing bodies, and—in principle—are quite compatible with the policy of the Government. The Scotch colleges, on the contrary, are ill at ease with the progress of the measure, and offer the most strunuous opposition.

Speaking generally, we may assert that all the parties to whom we have referred, are agreed that the Duke of Richmond's Bill ought to pass this session if it can be made compatible with the continued wellbeing of the licensing bodies, and coincident with the good of the public, and we are glad to understand that a means has been found which we hope may be considered sufficient to meet these necessities.

The Marquis of Ripon's amendment was, in fact, dictated by a desire to meet the case of the lady doctors. It was urged on behalf of these rather unaccommodating persons that they could not be reasonably asked to pay a fee towards the maintenance of licensing bodies as long as they were refused admission to the privileges of diplomates of those bodies, and that, therefore, the Bill should be framed so as to admit the ladies to registration and practice without either paying for, or holding, a collegiate diploma. But if ladies were to be admitted to registration on such terms, the same privilege must of necessity be extended to men; *ergo* it became necessary to do away with the necessity for any diploma, and hence, the contemplated subversion of the medical licensing system. There are, it is true, many who hold that it is unwise and unnecessary to legislate for so small a class as the female aspirants, and that—if admitted at all—these ladies ought to enter the profession by any way they can, or else remain out; but the general feeling is, that, if for no other reason, their demands ought to be met, lest the passing of the Bill might be imperilled. We believe that an understanding has been arrived at to meet the difficulty by the following means, *i.e.*, to have in the Bill the right of admitting to the Medical Register all those who pass the Conjoint Board, but with the proviso that if the medical authorities of any division of the kingdom make it part of their scheme that women shall be eligible to their diplomas, then—in that case—the diploma shall be indispensable, the scheme as so agreed upon having the force of law. Thus, if the licensing bodies of (say) Ireland agree together to admit women on exactly the same terms as men, then the women will receive the same diplomas, enjoy all the same privileges, and must be expected to pay the same as men; but if the licensing bodies should refuse such admission, then the ladies will, *ipse facto*, be admissible to the Register without diplomas and without paying for them. Thus, it is left to the discretion of the medical authorities of each division of the kingdom to decide the matter, but the ladies are not unfairly dealt with in any case. This appears to us to be a perfectly reasonable and statesmanlike settlement of the matter, and we entertain strong hopes that it may be accepted by Government and by Parliament.

The Bill was set down for its second reading on last Monday, but was deferred by consent until the coming week. It is opposed by Mr. Sergeant Simon in a motion to read it this day three months, but we imagine this is, to a certain extent, *pro forma*, and to ensure discussion.

Mr. Arthur Mill's Bill (which is the Bill of the British Medical Association, and is, practically, the Government Bill *plus* direct representation) got its second reading on Friday night last by consent, and it will be debated along with the Duke's Bill.

We may state, finally, that the principle of Conjoint Examination seems to be finally and definitely accepted and that the provisions of the Government Bill in this behalf will surely become law either this or next Session, but that difficulties present themselves still as to matters of most important detail, especially in regard to Lord Ripon's amendment, and that, until these difficulties are adjusted, the prospects of the Bill cannot be predicated.

THE IRISH APOTHECARIES' COMPANY AS A LICENSING BODY.

THE mind of the profession, and of the corporate institutions, whose business it is to consider projects of medical reform, have been so anxiously occupied by proposals for conjoint examination—extinction of corporations—reconstitution of the Medical Council, and other great questions that there is a present danger that less urgent, but still very important matters, may pass without the attention and the action which they deserve. One of these questions is the relation of the Irish Apothecaries' Company to medical licensing in Ireland and to the Board of Conjoint Examination which it is proposed to establish in that country. A few words of the history of that peculiar institution may not be inappropriate. In the reign of George III., the "Hall" was incorporated, its function being, as stated in the Act of Incorporation, "to promote pharmacy." In order to enable it to fulfil that function it was authorised to examine, and license pharmacists, inspect apothecaries' shops, suppress unlicensed practice of pharmacy, and generally to superintend the supply of pure drugs to the public. It opened a central establishment for the sale of genuine medicines, and this it did by means of shares taken up by shareholders, which shares are still a valuable property, inasmuch as all the earnings of the Hall, whether from drug-selling or from the granting of licenses, go to pay a dividend upon them to the holders. For many years the directors continued to pursue the functions thus confided to them with great advantage to the public, until, in an evil day, the chief influence in the counsels of the Company lapsed into the hands of a gentleman who, feeling apparently ashamed of the practice of the business of an apothecary, set before him for accomplishment a project of converting the Hall into a doctor-making body. With this purpose in view a curriculum was fixed, and examinations instituted, which included in their scope anatomy, surgery, physiology, and all the usual branches of medical education. As this project was developed, so the legitimate functions of the Company came to be neglected. Inspection of shops fell into abeyance, the practice of pharmacy by unlicensed persons became general, the sale of impure drugs was universal, and the final abandonment by the Company of its control of pharmacy in Ireland was consummated when the Poor-law Commissioners most improperly recognised the L.A.H. as a licence in medicine for the purposes of the Poor-law Medical Service, and accepted it as sufficient evidence of medical knowledge on the part of an officer of that service. But the plans of the secretary, who was the author of this scheme, failed after all, because the public would have none of the L.A.H. as a medical qualification. It was felt that an apothecary was, after all, for purposes of

practice, an apothecary and nothing more, and students looked with suspicion on the curriculum and the examination, and on the title of L.A.H. To entice them to the doors of the Hall the diploma fee of the Company was reduced to *half-a-sovereign*, but all in vain, for the number of licences fell away year after year until they reached the imposing number of *ten*, representing a diploma income of £5 to the Hall. At this period the Medical Act of 1858 was passed, and it was necessary to recognise a pharmaceutical body in Ireland, and, therefore, the Apothecaries' Company, being the only legal pharmaceutical corporation, was placed in the Schedule of the Act, and its licence admitted to registration; and thereupon, the secretary in question was crowned with the highest dignity to which he could have aspired—that of being elected to represent the Irish "Hall" in the General Medical Council. In like manner, when the Irish Conjoint Examination Scheme was in course of construction, it became necessary to permit the participation of the Apothecaries' Hall in it, because pharmacy had to be provided for in the conjoint qualification, and it was the only legal guardian of that art, however it might have shaken itself clear of its practice.

We are now on the eve of a reconstruction of the medico-educational system, and the question which we ask to-day is: What title has the Irish Apothecaries' Company to continue to occupy a place in the Scheme or to take any share in the qualifying of medical men? Originally consisting of sixty members, we find, on looking over the list of shareholders that the proprietors of the Irish Apothecaries' Hall are now, from negligence and carelessness of the directors, reduced to some twenty-one apothecaries, and that *fifteen* of these gentlemen, without any previous training for their position, annually elect each other for the important posts of Examiners and Directors of this Royal Charter Company.

The shareholders are now nominally forty-four in number, but of these twenty-three are the widows or other non-medical representatives of deceased shareholders, for whom the shares are—in order to evade the law—held by third parties who have no financial interest in the concern. Of the remaining twenty-one persons, fifteen are, as we have said, directors, and they manage the affairs of the corporation and annually re-elect each other, the Licentiates having no voice whatever in that or in any other of the Company's proceedings.

As a licensing body, the Company has ceased to exist. It has repudiated pharmacy, and, if it had not, Parliament has taken that guardianship from them and given it to the Irish Pharmaceutical Society. Its licences seldom exceed ten per annum, and they are granted, we assert, on the flimsiest examination. We are assured that a licentiate was lately qualified as a *medical practitioner* who failed to recognise aloes, poppy-head, colocynth, or gentian, or to suggest any way for detecting potash.

Having now no actual relation to pharmacy other than the keeping of an open shop for drug-vending, the Company has lost all claim it ever had to take part in a Conjoint Examination. It refuses to contribute pharmacy to that examination, and it is totally incompetent to contribute anything else. Are these fifteen gentlemen to be retained in the position of a Licensing Corporation endowed with a vote in the settlement of the affairs of the profession. Above all, are they to be longer permitted to send forth into medical practice and into the Poor-law Medical Service licentiate apothecaries for whose professional competency the world has no better guarantee than the *imprimatur* of an effete pharmaceutical institution.

The Government of the country has concerned itself about providing competent medical men for the service of the public. We fail to see how it can consistently recognise an institution like the Irish Apothecaries' Company as a means for providing such a class of practitioners, or how it can place the testing of students in the hands of a Corporation so false to its original purpose and so unworthy of trust as the Irish "Hall."

THE INTRA-VENOUS INJECTION OF MILK.

The ingenuity and enterprise of three American physicians have raised the question whether the injection into the circulation of fresh cow's milk might not be found to be a good substitute for the transfusion of blood. At present the novelty of the proposed practice is so great that doubtless many of our readers have never heard of it. Most of the facts before the profession will be found in a small pamphlet that has just been published on the subject by Dr. T. Gaillard Thomas, of New York, who entertains strong hopes that this substitution of milk for human blood will be found both a more practicable and more successful operation than that hitherto adopted. We must admit that the transfusion of blood is not an operation that has found much favour with the profession. As Dr. Thomas truly remarks, "it holds the position of an operation, the plausibility and theoretical advantages of which all admit, but the absolute utility and practical results of which amount to very little indeed." Many of our most eminent surgeons have never performed it, and many patients are dying among us without receiving the benefits which are claimed for it.

At first we might wonder that such an operation as that suggested and practised by Dr. Thomas could be ever entertained, considering the apparent want of homogeneity between milk and blood. This difference is, indeed, very great, but not so different is milk from that fluid, namely the chyle, by which the blood is being constantly replenished. The chyle collected in the receptaculum chyli passes up the thoracic duct, and, as an oily, white, milky-looking fluid is emptied directly into the left subclavian vein. The chemical constitution and microscopical appearances of the two fluids are not very different. Chyle is fat in emulsion in a serous fluid; milk is fat molecularly divided and suspended in water with casein and sugar; and they both contain about the same amount of salts. On theoretical grounds, therefore, the objections to the operation need not be so great as some may feel inclined to make; and if at present there is not much evidence that it has done much good, there is none to show that it does any harm.

The operation was first suggested to Dr. Thomas by the recollection of some cases in which it was employed twenty-eight years ago by Dr. Edward M. Hodder, of Toronto, Canada. In 1850 Dr. Hodder injected m[illegible]

into the veins of three patients moribund from Asiatic cholera. He injected as much as 14 ounces at one sitting; no alarming symptoms occurred; on the contrary, good results manifested themselves from the first, and two recoveries took place in patients who appeared moribund when the operation was resorted to. About twelve months ago Dr. Joseph W. Howe, of New York, adopted this method of transfusion in two patients. In one of them the operation was successful; in the other, a patient almost moribund from tubercular disease, it was not.

Donnè had also shown that milk might be injected into the veins of rabbits and dogs without injury to them; and Dr. Eugene Dupuy found that while the intra-venous injection of decomposed milk into dogs is uniformly fatal, the use of pure and fresh milk rendered the experiment entirely innocuous. Lastly, we have the cases of Dr. Thomas, the results of which were sufficiently satisfactory to encourage further inquiry into the subject. His first case was that of a woman on whom the operation of ovariotomy had been performed. Four days afterwards she appeared to be rapidly sinking, bathed in a cold sweat, temperature 101°, pulse 150, and a countenance expressive of approaching dissolution. Eight and a half ounces of milk were injected into the median basilic vein, with the transfusion apparatus of M. Colin, of Paris; and although one or two objectionable symptoms resulted, such as increase of temperature and headache, the patient ultimately made a good recovery. In the second case, also a case of ovarian dropsy, the operation for which was followed by dangerous complications, the result was not so satisfactory, as the patient did not recover. The next and last case was not a fair test of this method of transfusion, as the patient died from internal hæmorrhage after the operation of ovariotomy. Dr. Thomas concludes his observations by remarking that the intra-venous injection of milk is infinitely easier than transfusion of blood; and that it need not be limited to patients prostrated by hæmorrhage, but might be employed in disorders which greatly impoverish the blood, as Asiatic cholera, pernicious anæmia, &c.

We are not, however, so sanguine as Dr. Thomas is with regard to the future of "Intra-venous Lacteal Injections," and do not think it will take the place of transfusion of blood. The difficulties and dangers of the latter operation arise from the tendency of the blood to coagulate, and from the risk of admitting air into the blood of the patient. The first objection is usually got rid of by using defibrinated blood, while the second accident is just as liable to occur in the lacteal, as in the sanguinous injection. Nor is the injected milk so capable of being assimilated to the blood with which it is mixed, as the blood of another person would be; and indeed it is not so constitutionally analogous to the chyle as Dr. Thomas has represented. It does not, independently of its colour, bear so close an affinity to blood as chyle does, and consequently it cannot be so readily assimilated to the former fluid. It is, more than chyle is, in the position of a foreign body. By the time the chyle ascends the thoracic duct, it has become of a reddish tinge, several corpuscles resembling those of the blood can be seen in it, and like blood it coagulates directly it is removed from the duct containing it. Still, we will admit that theory is often wrong and practice right, and therefore we shall be glad to hear that the good opinion entertained of this method of transfusion by Dr. Thomas, is endorsed by that of other eminent physicians and surgeons.

THE ACCOMMODATIVE FACULTY OF HOMŒOPATHY.

It is sufficiently evident that globulism is on its last legs. A few weeks since we recorded a formal recantation of the schism by the vote of a large majority of the members of a Homœopathic Medical Society in America, and perusal of our exchanges shows us that, all the world over, homœopaths who are not prepared for formal recantation are seeking a way out of the dilemma by practising homœopathy only as an alternative, being perfectly ready to accommodate themselves to the tastes of their patients in the selection of a system of therapeutics. In the *Australian Medical Journal*, for instance, we find the following observations respecting the position of homœopaths at the Antipodes:—

At this moment the homœopath is no longer what his current belief presumes him to be. He gives real doses, or infinitesimal doses, accordingly as there is no need or a good deal of need for active treatment. Or he will make it optional with you to give you globules or real doses. You can take your choice, so long as you pay your money. As it is necessary, however, to keep up the credit of the system professed, whenever good results follow upon treatment they are set down as due to infinitesimalism and the magic of *similia cum similibus*. When occasion requires, this readiness to take either side is made no secret of, and in this way the homœopath sometimes is able to persuade the legitimate practitioner to meet him. There is, he points out, common ground upon which they can confer. He has no prejudice; Cæsar and Pompey are all the same to him. He will give half a grain of morphia or he will give the decillionth of a grain. He will dissolve ten grains of iodide of potassium in the Pacific Ocean and give you a drop of the solution, or he will give you the whole ten grains at a dose. His pliability is charming; his therapeutic cosmopolitanism overflowing. Some time ago a well known surgeon of Melbourne, on finding himself unexpectedly in the presence of a patient with one of these pliant disciples of Hahnemann, refused to remain. "Oh," said this latter, "you need not be afraid to meet me. I do not give any exclusive preferance to homœopathy; I *practise both ways*." Another who had been informed by Dr. ——— that he could not meet him in a case where he had been requested to do so, said, "But perhaps you would like to know what I have been giving the patient, as it may be some guide to you in shaping your own treatment?" "Oh, no," said Dr. ———, "that is quite useless, as your method has necessarily nothing in common with mine." "There you are in error," said the globulist, "for I have been giving five-grain doses of iodide of potassium." "But that is not homœopathy," responded Dr. ———. "No, it is not; but we are eclectics, we range over the whole domain of therapeutics, and so have the advantage of those who abide by allopathic doses." Now, says the *Australian Medical Journal*, this would be amusing if it were not shockingly dishonest. The non-professional public do not understand its immorality, and it is not to be supposed they should; but to all right-thinking persons, there is but one name for such a system of charlatanry. For if homœopathy were even remotely true, that system which we hold to be rational medicine is logically a uniform error. No honourable man can practise both methods, and to encourage a belief in the popular mind that they can stand side by side, is only a trick to bolster up the failing credit of the globulistic delusion.

We perfectly concur in the view adopted by our contemporary. A belief in infinitesimals and in the *similia similibus* dogma are as incompatible with the therapeutics which we practise as the creed of Juggernaut is with Christianity. There is no iota of fact or theory common

to both systems. Homœopathy may be the incarnation of truth, but, if so, allopathy is the embodiment of falsity and mischievous folly.

We commend this consideration just as fully to physicians who play "cat and pan" with homœopaths as to those practitioners to whom the *Australian Medical Journal* refers. No distinction can fairly be drawn between the physician who accommodates his opinion of the symptoms of his patient, and mitigates his advice as to the course to be adopted for a cure, in order to earn the consultation fees of homœopaths, and the homœopath who gives ten thousand of his doses in one in order to please the consulting doctor. Both are dishonest, both are guilty of sacrificing the patient to their own interests, both are disloyal to what they know to be truth, or else they don't know what the truth is. We regret to say that there are physicians (aye! and some of those who could, if they pleased, well afford to indulge their consciences with a little honesty of practice, and who would be transfixed by indignation if any one aspersed their social, professional, or moral characters), who yet will submit themselves to the indignity of aiding a person whom, if consistent, they must consider to be a charlatan, to practise principles which they know to be false upon the person of a helpless patient who has confided his health, perhaps his life, to their care.

To do his duty to his patient an honourable physician must, if he met a homœopath at all, tell the patient honestly and truly the opinion formed of his case, and the treatment recommended, and leave him to select for himself the cause to be pursued. Is it possible to do this in consultation and in prospect of consultative favours to come? Is it worthy of a gentleman to do otherwise?

Notes on Current Topics.

Diphtheria in St. John's Wood.

In Saturday's newspapers we have an announcement which is remarkably indicative of the times we live in, and of the change that has, within the last few years, come over public opinion with regard to sanitary matters. On Friday evening a public meeting was held at the Eyre Arms, St. John's Wood, "to consider the question of the present epidemic of diphtheria in the district." The chair was occupied by Prof. Huxley. The audience comprised a number of ladies, and several influential parishioners addressed the meeting. Such a meeting on such an occasion, would not have been thought of twenty or thirty years ago. If an epidemic broke out in those days it would have been regarded by the general public as a visitation of God, and no other steps taken to prevent its extension, or the occurrence of future outbreaks, beyond the use of a little chlorinated lime, and keeping a respectful distance from the infected. Now, however, owing to the repeated representations of the profession, and more particularly to the untiring zeal of such sanitary reformers as Mr. Simon and his coadjutors, both the Government and the public are fully alive to the preventibility of epidemic diseases, and to the nature of the precautions that should be taken to prevent them. As a result of this awakened interest on the part of the public in questions of a sanitary nature, we have the meeting in St. John's Wood above mentioned—not that the company present that evening was called upon to check the extension of the disease, inasmuch as the epidemic is virtually at an end. But much remains to be done by way of inquiring into the causes of the outbreak, and the best means of preventing its future occurrence, and the interest which the public has taken in the matter will be an additional inducement to the Government Inspector to make a thorough investigation into the subject.

Dr. Howell, who first addressed the meeting, was convinced that the outbreak was due to the escape of sewer gas, but, as we remarked last week, we doubt whether it will be proved to be entirely due to that cause. We would therefore endorse the reservation made by the Rev. Canon Duckworth, who reminded the meeting that some were of opinion that diphtheria was propagated by definite organic germs, so that when they talked about the disease being due to the escape of sewer gas, it should be remembered that sewer gas alone, without zymotic germs, would not have caused the epidemic.

Of course, too, the poor milkman came in for his share of the blame. A gentleman present said that three of his children were large consumers of milk, and they were the only members of the family attacked. The cans of the milkman who supplied his house were washed out with water from a well supplied by the Company's water, and his belief was that, owing to the heavy rains, the water had got contaminated. So at present there are, with respect to the etiology of this epidemic, the "sewer gas" theory, and the "contaminated milk" theory; but perhaps it would be better to wait for the forthcoming report of the Government Inspector before pinning our faith to any particular doctrine. In our opinion there is as yet no sufficient evidence to show that the outbreak is due either to the one or to the other of the two causes to which the disease has been attributed.

Colonial Degrees.

The clauses of the Duke of Richmond's Bill which admit colonial degrees to the Medical Register have been received with no little apprehension by the profession, and we ourselves have expressed our serious doubts as to the possibility of ascertaining the actual value of these diplomas, or ensuring that, at any moment of their recognition, they are equivalent as evidences of professional competency to the licenses of our Conjoint Boards. *On paper*, at all events, we are gratified to observe that some of these colonial licenses are above criticism for we find in the *Canadian Medical Journal* for the current month the examination questions of the Colleges of Physicians and Surgeons of Toronto, and are thus enabled to assure our readers that every diplomate of that body who has answered the written questions is, indeed, an emporium of professional knowledge. The papers for first and second-year candidates are twenty in number, including three on chemistry, three on anatomy, two on surgery, two on physiology, two on midwifery, and one each on microscopic anatomy, forensic medicine, botany, practice of medicine, toxicology, materia medica, and

sanitary science. The aggregate number of questions is *one hundred and fifteen*, which, being divided between two examinations, leaves fifty-seven written questions for each student, besides his *viva voce* examination.

If the *Canadian Medical Journal* would oblige us with a specimen of the answer paper of one of the monsters of erudition who have digested this dose, and eliminated a satisfactory result, we shall be able to appreciate the nature of the proposed legislation on colonial degrees.

Heroic Dose of Alcohol in the Treatment of Disease.

We should like to draw the attention of the authorities of the London Temperance Hospital to the very heterodox opinions and practice of Dr. A. H. Chandler, an American physician, with regard to the use of stimulants in the treatment of diphtheria. In an article in the *Canada Lancet*, he asserts "that alcohol in the form of whisky or brandy, given in large and frequently-repeated doses, at the very onset of the disease, is not only antidotal, but abortive and curative as well, in the more advanced stages." Children, he says, will bear half-ounce doses of alcohol every hour or two hours, and an adult from two to four ounces. Some of the cases Dr. Chandler cites bear testimony to the large quantity of alcohol which he gives to the patients suffering from diphtheria, so that he may be truly regarded as the Dr. Todd of American practitioners. Thus, in the case of an adult, we read, "Ordered brandy, two ounces every hour, night and day, no other treatment!" Forty-eight ounces of brandy, or more than two imperial pint bottles, is a pretty good allowance in these total abstinence days for twenty-four hours. In a girl, too, at 13, from sixteen to twenty ounces were allowed in the twenty-four hours; and what is more remarkable, these cases did very well, in consequence of, or in spite of, the treatment adopted.

American Hams and Trichinosis.

Professor Richard Heschel, the Viennese pathologist, gives a warning in the medical *Wochenschrift* to the consumers of foreign ham and bacon. He refers to the American ham which has recently found its way to Vienna, and is loudly extolled, at the expense of Westphalia hams, for its freedom from trichinosis. Dr. Heschel says, however, that while, among some 2,000 or 2,500 Westphalian hams one is infected, of the American hams inspected in North Germany, according to an official report, one in from five to ten is condemned, and there is great probability that several epidemics have been caused by trichinosis from American hams.

The Poplar Hospital.

Of all the hospitals in London there is none more deserving of support than the Poplar Hospital for Accidents. Although a few medical cases are received, it is, as its name implies, almost entirely confined to the in-door and out-door relief of patients suffering from all kinds of accidents. It is also situated near the East India Docks, where accidents are of constant and increasing occurrence; while the very situation and scope of the hospital exempts it from a charge that is often brought against other institutions of the kind, namely, that of not duly inquiring into the circumstances of the patients relieved, and thus allowing these charities to be abused by persons who can afford to help themselves. It appears also that greater demands are being made upon the resources of this hospital. From the Twenty-third Annual Report that has just been issued, it appears that the "total increase in the number of patients during the past year over the preceding one has been 195, the total number for the year 4,881; large as these numbers are, they can convey but a very inadequate idea of the frightful amount of suffering involved."

Notwithstanding the severity of the accidents admitted, it is seldom that a case of pyæmia or erysipelas occurs; and it is said that during one year more serious cases were received in the Poplar Hospital than in St. Thomas's in three years, and yet there was not one death from either of those diseases. We trust, therefore, that this hospital will have the hearty support of the charitable and philanthropic, for although the statement of the Committee of Governors is not discouraging, there is evidently need for continued and increased efforts for its efficient maintenance and prospective extension.

The West Riding Pauper Lunatic Asylum.

Every year brings with it some improvement in the sanitary or domestic arrangement or in the general management of our great lunatic asylums, and the one above mentioned is, in this respect, no exception to the rest. The Commissioners in Lunacy report that there is no record of the employment of either restraint or seclusion. One man is entered as having been once secluded for half-an-hour, and the only other case was that of a man with exceptionally violent homicidal and also suicidal tendencies; with him both restraint and seclusion have been used on several occasions since the 18th of June last, when he made a most desperate attempt to kill himself by beating his head against the wall.

Dr. Herbert C. Major, the Medical Superintendent, draws attention to the large part played by alcoholic excess in the causation of insanity, as the following table shows:

	Males.	Females.	Total.	Percentage on Admissions.
Alcoholic excess (singly) . .	30	5	35	7·5
Alcoholic excess with hereditary tendency to insanity .	14	5	19	4·0
Alcoholic excess with other *physical* exciting cause . .	9	4	13	2·7
Alcoholic excess combined with *moral* exciting causes	13	1	14	3·0
	66	15	81	17·2

It will thus be observed that in 81 cases, or 17·2 per cent., alcoholic excess either alone or in combination with other adverse influnces is considered to have induced the mental attack.

The mortality from small-pox greatly declined in London last week, when only 24 deaths were registered against 40 and 42 the two previous weeks; this is the smallest number of deaths since November last from this disease. There were 18 fatal cases in Dublin, but none in any other part of the kingdom.

The Relation of Examiners to the Medical Bill.

We find the following in the *Students' Journal*:—

"There is great consternation among the examiners connected with the Scotch and Irish examining bodies at the prospect of the Medical Bill becoming law. They fear —and with some reason—that, when the Conjoint Boards are established, their occupation will be gone. Now, to some of these Scotch and Irish, the fees received for examining candidates form a considerable item in their yearly incomes, and they can't very well afford to give them up. So they are moving heaven and earth, with a view to throw out the Government Bill; but it is to be hoped that they will be disappointed. They ought to have sufficient public spirit to forget self-interest and to do all they can to promote the passing of the Bill, seeing that the measure cannot fail to advance the interests of the profession very considerably."

We are obliged to remind our contemporary that it undertakes a serious responsibility in admitting to its columns a statement like the foregoing, in which we assert that there is not, *quoad* the Irish examiners, an atom of truth. We state as a fact that the aggregate fees of of an examiner in Ireland do not exceed £100 a year, and in most instances do not exceed £70; and that it is not true that any effort has been made or is likely to be made by Irish examiners to "throw out the Bill," but that on the contrary they are, by their representatives, anxious to pass it. In this connection we feel justified in complaining of the ridiculous unacquaintance with Irish medical affairs and Irish professional feeling by our metropolitan contemporaries. It may, perhaps, be asking too much to express a hope that our contemporaries should consult their Irish representatives before undertaking to express *ex cathedra* opinions on Irish subjects, but we are at least entitled to ask that if they do not consider Irish medical affairs worthy of this much notice, at least they should preserve silence upon a subject with which they seem to be insufficiently informed.

A Horrible Superstition.

It is an undoubted fact that even down to the time of Sydenham "mummy" was held to be a drug of great curative power, and was extensively administered in cases of fever and ague. But what should be said of the administration to a patient of human flesh freshly taken from the living subject? This exceptionally appalling medicament, says the *Daily Telegraph* of Monday last, seems to have been made use of under very singular circumstances in China. An application has just been made to the Emperor from the Governor-General of the province of Kwang-Tung, for permission to erect a memorial structure in honour of the filial devotion of a young lady twenty-one years of age, the daughter of a magistrate of Canton. In the spring of last year, this young lady's father fell ill, and was most tenderly nursed by his devoted daughter. At the end of six months the old gentleman became much worse, whereupon the young lady cut a piece of flesh from her arm and mixed it with his medicine. The remedy proved fatal to the patient: and his daughter, who had vowed to sacrifice her life for his, poisoned herself on the same day that her father died. This melancholy story of heroic filial piety, mingled with the most barbarous ignorance and superstition, may be instructively read in juxtaposition with a letter received in Shanghai from the Roman Catholic Bishop of Shanshi. Says Monsignor Monagatta, who is resident of Tai Yuen, the capital of a province in which famine is just now raging with the most fearful severity, "Until lately the starving people were content to feed on the dead; but now they are slaughtering the living for food. The husband eats his wife; parents are eating their children; and in their turn sons and daughters eat their dead parents. This goes on almost every day." Cannibalism has in a more or less marked degree been an attendant horror on the majority of great famines; but the systematic eating of human flesh in a time of scarcity is hardly to be wondered at in a country where young ladies of rank, education, and intelligence grow up to be twenty-one in the belief that a piece of human flesh can be beneficial as an inward medicament.

Catalogue of the Plants in the Society of Apothecaries' Garden at Chelsea.

We would draw the attention of our younger readers to a very useful pamphlet, edited by Dr. R. H. Semple, and containing not merely a dry catalogue of the medicinal plants in the Society of Apothecaries, but also a short description of the grounds, illustrated by three or four excellent plans. The plants are so classified, and the plans and directions are so plain, that the medical student can, with the assistance of this catalogue have no difficulty in finding any plant or class of plants he may wish to study. Plan I., for example, shows the manner in which the garden is laid out. Plan II. is a key to the beds of hardy medicinal plants, arranged after De Candolle on Plot A of Plan I. Here it will be seen that each bed contains one or more natural orders. Plan III. shows beds of hardy medicinal plants, arranged after Lindley on Plots B and C of Plan I. Altogether it is a very useful catalogue, and as it only costs sixpence, a very cheap one too. We hope that students will make a good use of it, for as a rule they show before the different Examining Boards a lamentable ignorance of the natural orders of plants from which our most valuable medicines are derived.

Irish and Scotch Colleges.

In the course of the warm controversy which has arisen out of the Duke of Richmond's Bill, we have observed that the Irish and Scotch licensing bodies have been classed together as the institutions against whose educational underselling the Bill is directed. We have read from the pens of editors who ought to know better that conjoint examination has become necessary because the "Scotch and Irish Colleges" have kept down the educational standard of the profession by the facility and cheapness of their diplomas. We do but justice to the Irish bodies, and especially to the Irish College of Surgeons, when we assert emphatically that such a statement is calumnious, and that that College so far from being a sinner in this respect, has been the greatest sufferer of the underselling system elsewhere.

Without entering into a comparison of its curriculum and examination with that of the English bodies, by means of which comparison we could readily prove our case, we meet the assertion by pointing out that, as a matter of fact, the Irish College of Surgeons does not

license three students per annum from the "preserves" of the English Colleges. This fact may, perhaps, be interpreted by caprice in a sense unfavourable to the status of the college, and to its prestige; but without discussing that point we claim the fact as clear proof that the Irish College of Surgeons does not seek to attract students by keeping down its curriculum, making its examinations easy, or cheapening its diploma; but that, on the contrary, it has for long years sacrificed to the competition of the Scotch bodies, and of the local cheap university, at least one third of its licensing income, sooner than descend to bidding against these institutions for the patronage of the student. Until these statements can be refuted, we trust that those who institute a comparison between the merits of various corporations will cease to bracket the Irish College of Surgeons with other colleges, with whose aims or methods it has no sympathy.

Therapeutical Paradoxes (Sensational Therapeutics) III. (a)

Mr. C. S. Wills states in the *British Medical Journal*, February 2, that he has used capsicum for more than twelve years in the treatment of *delirium tremens* with "unvarying success." It has never failed, he remarks, no matter how violent the patient may have been. In extreme cases thirty grains in a bolus may be given every hour, but milder cases simply require smaller doses.

We all know how troublesome these cases are to manage, and if Mr. Wills has found a sovereign remedy for this complaint in the administration of half a teaspoonful of cayenne pepper, the profession and the public will have much to thank him for. How Mr. Wills, however, could get a man suffering from a severe attack of delirium tremens to swallow a bolus every hour, is not so easily answered. Patients of this kind are often very unmanageable, and they might be inclined to resist such a pill under the idea that they were swallowing bullets. Nor do we quite see the *modus operandi* of such a remedy. We are aware that the sympathy between the stomach and the brain is very great, but should scarcely have thought that any impression made upon the former organ would have had so salutary an influence upon the latter. Otherwise it might be said that the capsicum acted upon the stomach like a sinapism, and on the principle of derivation, "attracted" as the old physicians would say "the morbid spirits" from the brain to the stomach. In many cases, however, of delirium tremens the stomach has been already pretty well stimulated by the alcoholic libations in which the patient has been indulging, a condition which would be scarcely improved by half-drachm doses of capsicum every hour.

We now turn to a very different disease, one that has been the butt of nearly every remedy under the sun. Indeed, so many remedies and plans of treatment have been vaunted as a cure for *acute rheumatism*, that, unlike others we have noticed, there is not much novelty in the simple treatment that has been recently recommended by Dr. M. J. Guerin, in the *Archiv. Gen. de Medicine*. This physician states that he has been able to abort acute articular rheumatism by the inunction of an ointment of one part of tartar emetic, and two parts of lard. This inunction is repeated every six to eight hours. A rapid reduction of the pain and swelling is said to occur, a result which Dr. Guerin attributes to a dynamic action of the remedy. The same treatment was equally successful in gout.

The production of artificial eruptions by the inunction of tartar emetic ointment, and the use of embrocations, blisters, liniments, and rubefacients, were long ago resorted to in the treatment of rheumatism, but nearly always in the chronic, and very rarely in the acute, form of that disease. It used, moreover, to be the fashion to put the patient suffering from *acute* rheumatism under a course of blistering. That plan, however, has had its day, and now we seldom hear of it. Dr. Guerin's method is in some measure a revival of a plan of treatment which was never employed to the exclusion of other remedies, and which, even as an adjuvant, never had strong recommendations. It was adopted by two or three of the older physicians whose names are now seldom mentioned, and it soon fell into deserved obscurity. Our knowledge of the pathology of acute rheumatism may not be perfect, but we do know this much, that there is no more chance of cutting it short by the use of irritant ointments than there would be of arresting by the same means the course of typhoid fever or small-pox.

Metropolitan Hospital Sunday Fund.

On Sunday next, the sixth annual collection in behalf of the metropolitan hospitals and dispensaries will take place, when every one will have an opportunity of contributing towards the expenses of maintaining institutions devoted to the sick and suffering poor of London. The annual deficiency this collection is intended to meet amounts to something like £50,000, and prior to the establishment of this Fund, hospitals and dispensaries solely depended upon the voluntary contributions of the benevolent to keep them out of debt. A wish was expressed, at the Council meeting of the Fund held last week at the Mansion House, that the amount contributed might possibly be increased, if only the whole of the services of churches and chapels could be devoted to the advocacy of the Fund. Mr. Jabez Hogg, seconded by Dr. Hamilton, and supported by Professor Marks and Bishop Claughton, moved a resolution to the effect that the clergy and ministers of the abbey, cathedrals, churches, and other places of worship in the metropolis be earnestly requested to allow all the services performed on Sunday, the 30th, to be made available for the general collection on behalf of the Fund. The Lord Mayor and Sheriffs will attend as heretofore, at St. Paul's morning service, and Westminster Abbey afternoon service.

The General Medical Council.

Although the Parliament of the medical profession has already held its annual session, it was expected in

(a) Taking the liberty accorded to every writer, that of changing the title of his subject, we have substituted the above heading in place of that previously adopted. It is perhaps less objectionable than the hackneyed word "sensational," and it has been suggested to us by calling to mind the very amusing "Budget of Paradoxes," which appeared some years ago in the columns of the *Athenæum* from the pen of the accomplished mathematician Mr. De Morgan, and in which the author reviewed and ridiculed the extraordinary and absurd opinions of certain *soi-disant* mathematicians.

view of imperial legislation upon medical matters that the necessity might arrive for another sitting; and we understand that a special meeting of the General Council has been summoned for Friday next, to consider the Bill of his Grace the Duke of Richmond for the amendment of the Medical Acts.

Increase of Medical School Fees.

Recently delegates from the staffs of the London medical schools have met together for the purpose of considering the necessity of increasing the fees to be paid by students. The majority of the London medical schools, and some also of the provincial schools, have decided upon raising the fees 25 per cent. from October next. The Scotch and Irish are still considering the matter, and three of the London schools refuse to join in the scheme. It is only just that the compounding fee should be raised. The sum charged to students of medicine bears no correspondence with the education received, and is altogether out of proportion to the sum charged in every other department of education. Further, it must be remembered that the corresponding fee at the different schools at the present date is precisely the same as it was a quarter of a century ago, notwithstanding the fact that the courses of lectures have increased nearly twofold, and the care and attention paid to students are now incomparably greater. No student on paying the higher fee could complain of it as an exorbitant charge, and it is to be regretted that the movement is not unanimous throughout Great Britain and Ireland. The policy of the new English schools who withhold from the movement is incomprehensible; it is not with them a question of principle or of justice: for the reasons we have referred to, it might be termed a policy of prudence, but we doubt whether students or their parents will be induced to enter into a contract with a medical school because the fees are a little lower than at the others. Underselling has proved of no avail up to the present time, for at the medical schools where the fees are small the annual entry of students is also small, but we are inclined to think that should any school ultimately refuse to act with the rest in this matter the fee for compounders, with its attached stigma, will prove repulsive rather than attractive to the students of the future.

The Case of the Rev. Mr. Dodwell.

On Friday last Dr. Forbes Winslow and Dr. Winn had an interview with the Rev. Mr. Dodwell, by the sanction of the Home Secretary, at the Criminal Lunatic Asylum, Broadmoor. This is the third visit they have paid him. In their report to the friends of this unfortunate gentleman they have again expressed their decided opinion that he is perfectly rational. They found him calm and collected; he gave, as on former occasions, a clear and logical account of the motives which impelled him, by the force of circumstances, to commit a breach of the peace in shooting at the Master of the Rolls. It has been proved and admitted that he had not the slightest intention of commiting a murderous assault. Why, then, is he still incarcerated on the ground that he is a dangerous lunatic? He is no doubt a man of strong feelings and determined character, but these peculiarities do not constitute him an irresponsible agent. It may be argued on the part of the medical authorities of Broadmoor Asylum that he has a morbid sense of his grievances. Some men are keenly sensitive to insult or injury. We may ask what constitutes a morbid sense of a grievance? Is a man supposed to have a sane sense of his wrongs when he can bear to be kicked to any extent without a murmur.

Mr. Thomson, of the Richmond Hospital, performed ovariotomy on Monday, the 17th inst. The woman was aged 40, and multiparous. The tumour had been first noticed six months ago. The operation was done under thymol spray, and on the fifth day the wound was found united throughout. Temperature, pulse, and respiration were normal.

The rates of mortality last week in the four principal cities of the United Kingdom, per 1,000 of the population, were: in London 19, Edinburgh 22, Dublin 26, Glasgow 27. The only other large town that reached this figure was Sunderland, the death-rate in the majority being excessively low, such as Leicester 11, Oldham 12, Brighton 14, and Plymouth, which a few weeks ago was the most unhealthy town in the kingdom, now presents a very clean bill of health with only 15 per 1,000 of its population.

Correspondence.

TOTAL ABSTINENCE IN THE ARCTIC REGIONS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—A letter appears in a recent number of the *Medical Press* inviting attention to a surprising instance of the success of total abstinence in sledge travelling. Since the return of the late Arctic expedition, many similar letters and addresses have appeared from time to time, and your correspondent's letter deserves as much notice as most of them. The abstract of a sledging journey which he quotes is, he very modestly presumes, quite enough "to convince the most sceptical." It appears to me, however, that to have done himself full justice he should have contrasted this great teetotal sledge journey with the most successful, or rather, least unsuccessful, of the sledge journeys in which alcohol formed part of the ration. The longest of such journeys is that in which Sir Leopold M'Clintock, averaging 12 miles a day, marched 1,400 statute miles, in the hope of rescuing Sir John Franklin. The sledge crews—on similar rations—led by Admirals Richards, Sherard Osborne, and Sir Edward Parry, approached, but never exceeded, this distance. On the other hand, your correspondent brings to our notice the Arctic voyager, Wiggins, who volunteers to command the forthcoming teetotal Arctic expedition; who has "never yet taken spirits of any kind whatever to sea with him in these expeditions;" who now tells us of his sledging journey of 8,000 miles, during which he accomplished for days together, 200 miles per day. Comment on this astounding success of total abstinence is superfluous; but one of the striking incidents of the journey appears to call for explanation. It is by no means clear why, if there was no alcohol in the expedition, a non-abstainer belonging to the same sledge should have been "knocked up" by the severity of the journey *until he adopted total abstinence*. Your correspondent unmistakeably refers to Arctic explorations and sledging journeys. I should like to have seen a copy of *The Temperance Record* from which he quotes, but I could not find that publication on any library table in Dublin, or at the Westmoreland Street offices for the promotion of total abstinence. I should like, I say, to have seen Captain Wiggin's own report, because it sometimes happens that in making an abstract the eye wanders off to the wrong page or the wrong book, and some of the details quoted by your correspondent seem more applicable to a

journey by railway, or some other kind of conveyance, than to a toilsome march in the drag-belts of an Arctic sledge.

The proposition for a teetotal Arctic expedition was, I believe, first brought forward rather more than a year ago, at a temperance meeting in Leeds, where, according to the local papers, one of the speakers after descanting upon the assumed effects of alcohol in the late Arctic expedition, informed the meeting that one of the men reported dead, had nevertheless turned up safe and at sound his own home. This was even more startling than the statement published in one of the three leading London papers, that the exhausted men were hung up by the heels in the rigging until they recovered. If such gross irregularities occurred, it was indeed time to advocate temperance. Another speaker held up expeditions in which alcohol formed no part of the ration as a bright example for imitation. Three such expeditions had preceded the recent one in Smith's Sound; no one of the three accomplished any sledging worthy of the name; two of them lost their ships; in two mutiny occurred. The published records of one of these model expeditions tells of an attempt to assassinate the officer of a sledge party.

And in evidence before a Government inquiry into the suspected poisoning of the leader of another, the second in command confesses that he surreptitiously drunk the spirits supplied for the naturalists' specimens. So far as the recent expedition is concerned, anyone who spends a few hours over the copious official records in its Parliamentary blue books, can ascertain that there is no foundation whatever for the statements that total abstainers enjoyed any immunity from scurvy. The only people who could be said to display such an immunity, were the officers, who not only had (when they chose to take it) the same allowance of spirits as the men, but had sherry or madeira as well. The abstainers in the expedition suffered slightly more from frost-bite than their non-abstaining companions. This was altogether accidental, but it prevented some of them being sent in the extended sledging parties, amongst which scurvy was most severe. Now Sir, I am no opponent of total abstinence; on the contrary, I hope and trust that it and temperance will grow and flourish side by side, but I believe that the total abstinence movement is yet in its infancy, and I consider it especially unadvisable to feed it with "false stimulants," in the shape of statements so very hard of digestion as some of those brought forward by its mistaken friends. So long as teetotalism is occasionally embraced as an assistant to defective moral volition, long-tried habits of self control will have at least an equal value in the eyes of a man selecting companions for the uncertain and hazardous trials of an Arctic expedition.

It is not amongst picked bodies of men without, so far as can be ascertained, physical or moral spot or blemish, whose lives from their boyhood have been constantly under observation, and who are subjected to the strictest discipline in the world, that temperance agitators will find their most telling atrocities. Surely we need not stray into high latitudes and low temperatures to find the evils of moderate or excessive alcoholism, so long as we live in the midst of a morally paralised population draining from our gin palaces, and so-called groceries, into our hospitals, our lunatic asylums, and our prisons.

Yours, &c.,

ZERO.

THE PURIFICATION OF WATER.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—If anything were wanting to confirm my statement of the "chalybeate" character imparted to water by the spongy iron filtering process, it has been abundantly supplied by the Company themselves, as it is evident by their letter of the 27th ult. that they were suffering from what I have heard medically described as "bungacious irritability," a very frequent result from a certain want of action induced by mineral tonics; hence, I make every allowance for Prof. Bischoff's hard words, and the only thing that annoys me, is the persistence of his extreme modesty in not letting the public know that he is the alpha and omega of the Spongy Iron Water Purifying Company, instead of leading it to suppose, when reading his numerous papers dilating on the wonders of spongy iron, that it is solely on sanitary grounds that he discourses so melodiously on the virtues of that material.

Now, as regards my assertions, which he so delicately puts it, as being throughout so inconsistent with truth, I will at once candidly admit that no doubt Prof. Bischoff can adduce *eight* official reports as to the superiority of spongy iron; but as an official report usually emanates from one person's deductions, let me ask the learned Professor how that in any way carries any proof with it, considering that against his *eight* I can bring *eight times* that number to proclaim the superiority of animal charcoal.

I am also bound to acknowledge that my obtuseness of intellect is such that even now I cannot grasp why reports respecting the value of animal charcoal should be *obsolete* merely because they were the deductions of careful chemical investigations extending from 1866 to 1870, unless, indeed, some of those wonderful Darwinism metamorphoses are developing themselves in the bones of animals which have suddenly changed their hitherto recognised chemical properties (in a burnt state), and transmitted their virtues into the pores of spongy iron. But why the learned Professor's foreign bantling should be the favoured recipient in preference to those emanating from the father of filtration through various preparations of iron (Mr. Spencer) is what, I for one, cannot understand.

Respecting Prof. Bischoff's wonderful mechanical ingenuity in the construction of filters—as illustrated in the last paragraph of his letter—I will quite believe it; but did it not strike him that as the filters of the London and General Water Purifying Company are on the syphon principle, and the grossly defective point to which he alludes is frequently half the time out of water, it follows that if when under water it allows water to be sucked in, when out of it, air would enter in its place, and the action of the filter at once stop; and if this were the case, it is only wonderful that this Company should still be in existence, after so many years trial, as the public is not so considerate as to put up with the inconvenience of being without water the greater part of the day, which would be the result of so faulty an arrangement.

I strongly suspect a joke has been played on the learned Professor, and if he will only favour me with a visit I will with pleasure show him how to make a joint, not only water but *air*-tight, which he will find far simpler than trying to imbue the public with a love for spongy iron water.

I remain, Sir,

Your obedient servant,

R. RUDING.

THE NEW MEDICAL BILL.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I have read of late many articles, including your own, on what one may designate the Medical Reform Act, which has been to my mind most mischievously hurried on by the week-minded inconsistencies and petty jealousies of medical men. I have had various opportunities of hearing the remarks of those who are well able to pass an opinion on the subject, whether in its favour or in condemnation; but I have been much surprised to find that the real *canker-worms*, the unseen uprooters of the profession, have been passed over either through culpable ignorance or blinded partiality; that the degradation into which the medical profession has fallen has been thrust aside by those who, in plain language, ought to have known better.

I confess I cannot find words to express my contempt and condemnation when I see men prominent in the eyes of the world stand forth and cavil about empty titles which, in the main, are completely useless, and yet ignore the many unprofessional and degrading practices of a *large* class of medical men, including not a few of those who possess that title (doctor) which is the bone of contention, and on which so many articles and letters have been penned, as if it were the most important question for discussion.

In this Medical Act, if it ever should become law, many a good old landmark will be swept away and cast into oblivion, and some new ones will be erected, the stability of which I very much question; for as reform seems to be the cry of the day, I suppose the same will occur again, for no doubt the future reformers will be as destructive as the present, and will be equally ready to pull down what we have erected, as useless and obsolete.

Reform is beneficial when it is in the right direction, but if it is in the wrong, Heaven help us! and I am sure that the Medical Act which is now engaging the attention of all those interested in the medical profession, instead of being a boon will prove almost akin to a curse, for it leaves untouched a great number of men who are a blight to their

better-conducted brethren—I refer to those medical practitioners who keep shops, and who are consequently no better than tradesmen; who extract a tooth for a shilling; who trade in pennies; who make up prescriptions; who sell combs, brushes, and scents, and quack medicines; who stick over their shops "doctor," "surgeon," or "surgeon-accoucheur," as the case may be. This is the class of men *we* ought to be protected against; and, forsooth, *this* class of miserables the Act leaves untouched.

Is it fair, is it just that chemists should be prosecuted for counter-practising and doctoring, when medical men openly encroach on the trade of the chemist? Why do not the promoters of this farce of a Medical Act give their attention to this anomalous state of things, instead of muddling their heads about professional titles and other minutiæ in order to suit the caprices of the querulent? Why do they not fix a standard of fees, as it is in the legal profession? Why do they not prevent medical men keeping shops? Why, if they are so anxious to prevent physicians using the title of doctor, do they not prevent apothecaries prefixing surgeon to accoucheur?

I repeat emphatically what I said at the commencement of my letter: that this Act, or rather *miscarriage*, has been hurried on by the inconsistencies and petty jealousies of medical men—inconsistencies, *i.e.*, keeping shops, accompanied with its innumerable degradations; petty jealousies, because an M.D. refuses to call a physician a doctor; and an M.D. of London thinking himself a better man than an M.D. of Edinburgh or of Dublin; and a Fellow imagining himself superior to a member.

Sir, I could enumerate many other instances and other evils which this Act does not mention, but my time is precious and your columns are well occupied.

Yours, &c.,

VALE.

[We have thought it well to allow our correspondent to express in our columns his views because they represent, no doubt, the ideas of medical reform held by many of the rank and file of the profession. Our correspondent ought, however, to understand that Acts of Parliament cannot prevent a medical man "keeping a shop," trading in "pennies," selling combs, scents, brushes, and quack medicines. All these are matters of private feeling. A medical man may degrade himself and his profession by going about unwashed and disreputable in appearance, but it is as impossible to force him to look respectable as to act respectably. Colleges may take notice of such matters (and we much regret that they do not oftener do so), but laws cannot, and the best way of putting a stop to such medical trading is to insist on medical men having an education which will raise them in mind and pocket above such a line of business.—ED. M. P. & C.]

LET US SPELL!

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—The literary world in general, and the medical in particular, must feel under heavy obligations to Dr. George Harley for the sturdy manner in which he has lately inaugurated his new spelling reform. Of course it must be confessed that the reader—I speak from my own experience—is likely to be more or less distracted from the subject-matter of a communication, very interesting and instructive in other respects—by his constantly meeting with words spelled entirely different to what he had been accustomed. The meaning of terms also may be rendered doubtful by the new system of *orthography*, as, for instance, when such a word as "needless" is converted into "needles." *Rem acu tetigit!* But this, after all, is a matter of little consequence, as we should soon get used to it; as, indeed, we daily do to things quite as extraordinary in this sublunary world of ours.

However thorough and seductive Dr. Harley may consider his reformation, I for one beg leave to pronounce it sadly inadequate for the end in view; it does not, in my opinion, go far enough. In order to give full perfection to the method in question, not only the duplicated consonants should be omitted, but the double, and therefore redundant and unnecessary vowels, should also be abolished. To give an example, instead of writing, as in the old obsolete (?) way, "Your field, friend, is well tilled," we should put it in this fashion: "Your feld, frend, is well tiled." This *I* consider to be the acme of perfection; and must, I am certain, commend itself, on a little reflection, to all persons of discriminating and refined taste. But in order the better to insure its universal adoption—for nothing short of this would satisfy me—I would suggest that "Spelling Bees" be started at once, and on a far larger scale than they have been heretofore.

Not wishing to deprive Dr. Harley of any share of the honour and glory of his last, but not least, achievement, and as, moreover, it might be as inconvenient for the same age and country to possess two reformers (even in the medical profession) whose claims to immortality might be equally balanced, as it was intolerable in the time of Alexander for Asia to have two kings, I shall, sir, with your kind permission, humbly subscribe myself,

Yours, &c.,

EXCELSIOR.

THE VICE-PRESIDENCY OF THE IRISH COLLEGE OF SURGEONS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

GENTLEMEN,—As the contest for the honour of the Vice-President's Chair has commenced, those feeling an interest in the fray must begin to arm, while at the same time negotiation or argument may be brought into play.

I am an unwilling participator in the struggle, and it will go hard with me to oppose a man for whom I entertain such a profound respect, as I do for Dr. McClintock, one whose status, character, and writings, entitle him to the highest honours that the College can confer; but a sense of duty to the higher interest of the profession at large, constrains me to assume the position of being an antagonist. It was generally felt that when the late Dr. Mackesy was elected to the presidential chair, any inconvenience consequent on the distance of his residence from Dublin was more than counterbalanced by the general advantage to the profession at large. That in choosing a country practitioner for that high office, the social status of the provincial practitioner was enhanced, an idea I have good reason to know to be well founded.

It has since been over and over again stated very generally by the Dublin Fellows that this step should be repeated every six or seven years, and I myself have repeatedly asked to become a candidate for the chair; a course I fully intended a few years ago to take in due season, relying simply on my position as a country practitioner of respectable standing, and in no way having the vanity of putting my professional attainments in contrast with those of the eminent metropolitan practitioners who have sought the honour.

Circumstances have occurred which preclude me from seeking college honours for a long time, if ever; but "Rome hath many a worthier son than he" and a country practitioner now seeks the votes of the Fellows; one who is in every way qualified for the position; surgeon to a large hospital, in extensive practice, and living within such easy distance and access to the city that no objection could be made on the score of inconvenience. Nearly twenty years have elapsed since Dr. Mackesy sat in the chair. It is now a provincial man's turn, and I respectfully call on those Dublin men who have so kindly and so loudly called for a member of that section to come forward, to remember what I venture to call their engagements and vote for Dr. Chaplin.

I call on the country Fellows to be united and stand for their order, to set aside selfish ideas of ease and take an active part in the movement, and show how they value the prestige which accrues to the body by the selection of one of its members for the high office.

I feel strongly on the subject, as I would not oppose Dr. McClintock, and wish much that some other man was our opponent; still I think that in such a case the contest being between classes, not individuals, that the usual delicacy as to canvass may be set aside, and that a committee should be formed to carry out our object.

That Dr. Chaplin would most probably be a candidate has been well known for some time, and indeed I may say was very lately made the subject of compromise. The country practitioners turn is due, and if the country Fellows be loyal to their own interest, and that the opinions I have heard on the subject from so many leading Fellows in Dublin be still held, I have no doubt as to the result. I am sure there are few who would not engage with me—our point having been obtained—to support Dr. McClintock the following year. Apologising for the liberty I have thus taken in addressing you,

I am Sir, your obedient servant,

J. W. MARTIN.

Literature.

DISEASES OF THE NERVOUS SYSTEM. (a)

In looking over Dr. Althaus' recent volume, we are struck with a feature at once novel and important—viz., the statistical tables which appear to have been carefully and correctly drawn up from the Registrar-General's Annual Reports. In this way an attempt is made to show the frequency of these diseases at varying periods of life, and the average mortality in the male and female in England and Wales.

We have no wish to detract from the value, which at first sight, these statistics appear to possess, or from the credit which is due to the author for his laborious undertaking. But we are from common experience compelled to differ from him when he speaks of having addressed himself "to that large storehouse of facts—the Annual Reports of the Registrar-General on disease and death in England and Wales."

And we ask the question simply and in good faith—are these "dry and repulsive volumes"—storehouses of *facts?*

We do not doubt the correctness of the Registrar's Reports, but in the question of diseases of the nervous system, we are very much inclined to discredit the accuracy of the diagnosis, not from any want either of skill or care on the part of the diagnostician, but from the difficulties which beset the true understanding of the signs and symptoms of this class of disease when attended with an insufficient history.

We will take apoplexy by way of example.

A man in advancing years, or not, has a fit, and dies comatose. He may, perhaps, fall down suddenly. The cause of death, if no *post-mortem* examinations were made, would be stated to be apoplexy, and with apparent good reason. Yet in a large proportion of cases, no hæmorrhage has taken place either into the brain or its membranes.

We merely quote this to show that these statistics are not without serious sources of error, and we could bring forward good evidence to prove that many forms of internal hæmorrhage from the rupture of aneurisms may, unless due care be exercised, be referred to the brain, where this organ is exempt from disease.

To one who knows the exigencies and surroundings of general practice (especially in country life) where, at all events, until recently, certificates of death have been filled up by unqualified men, by whom the majority of diseases are conveniently referred to fever, the brain, the heart, and the lungs, scepticism as to the intrinsic value of the Registrar-General's Returns in reference to diseases of the nervous system, must necessarily exist.

With regard to the absolute subject matter of this volume, few exceptions can be taken. The author has clearly and definitely brought before us the signs and symptoms of each class of nervous disease in a manner at once comprehensive and truthful, and in every way equal to the more recent literature of the subject, which we know embraces a very wide field; and he can well be excused for having passed over lightly certain of the less common forms of disease, whose precise nature and pathology have not as yet been so well ascertained.

The reader may rest assured that he will not be wearied by any superfluous material. Every page of the book gives evidence that the author has made a complete and thorough digest of his subject, and that no pains have been spared to give the work a prominent position among the medical literature of the period.

Dr. Althaus proposes to give the name of "Charcot" to that form of disease which is known as "disseminated insular sclerosis," although he states that the malady was first described by Cruveilhier, and afterwards studied by Türck, Rindfleisch, Zeulker, and Frommann. If he wishes to pay M. Charcot a compliment, we cannot see that this is a fitting opportunity. But in the present age of diffuse nomenclature, we think the suggestion of Dr. Althaus unfortunate, and we strongly condemn the practice of giving to any special disease the name of the man who first drew attention to its especial characteristics.

There is too much vagueness in medical nomenclature, and a growing tendency on the part of specialists to create new names upon the most trivial and assumptive premises.

We not infrequently find men, for want of a better understanding, give five or six varieties of nervous disease the name of "Duchenne," and we are quite sure that M. Charcot would be sorry to see his name so mauled. Let our nomenclature be as classical as you please, but when it is possible, give us ungarnished Anglo-Saxon rather than hybrid nonsense.

Why not call the blood "Harvey's fluid," or small-pox "Jenner's disease?"

Dr. Althaus promises us another volume on the pathology of peripheral nerve diseases, and the diagnosis, prognosis, and treatment of the entire class of these maladies.

We shall look forward to this with interest, and if it is in all respects equal to the present volume, it will be most welcome.

(a) Diseases of the Nervous System. By Julius Althaus, M.D. London: Smith, Elder, and Co., pp. 360. 1877.

Literary Notes and Gossip.

We understand that the first edition of Messrs. Hanbury and Fluckiger's "Pharmacographia" has run out of print. The second edition will not be ready until October.

* * *

By the death of Earl Russell, the Presidency of the "Royal Historical Society of Great Britain and Ireland" has become vacant, and the post, which is honorary, has been offered to and accepted by Lord Aberdare.

* * *

We understand that Dr. J. Stannus Hughes, professor of surgery in the Royal College of Surgeons of Ireland, is engaged on a third edition of his "Treatise on Diseases of the Prostate Gland."

* * *

Another work from the fertile pen of Dr. Milner Fothergill, "The Antagonism of Therapeutic Agents," has just appeared. This and De Watteville's medical electricity are the only two new medical books issued during the past week.

* * *

By the death of Sir Thomas Hardy, keeper of the public records, historical literature has sustained a great loss; his researches in ancient history have given him a world-wide reputation, and caused him to be styled "The Jupiter of History."

* * *

Mr. De Watteville, assistant physician to the Hospital for Epilepsy and Paralysis, has just issued a translation of Dr. Onimus's "Introduction to Medical Electricity." Practitioners in this speciality ought to be thankful for the multitude of small and large manuals on the subject; but this advantage is not without alloy, as the difficulty of selection increases with the enterprise of authors.

* * *

The museum at University College, which is to perpetuate the memory of the late Dr. Parkes, F.R.S., is progressing satisfactorily. When finished it will contain an excellent library, which is intended as a centre of reference for every known work on hygiene and matters relating thereto. The larger hall will be furnished with plans and models of military and naval hospitals and other objects of interest to the sanatarian.

* * *

A fund has been started by an influential committee of literary and scientific men for the purpose of presenting Mr. Le Neve Foster with a substantial testimonial on his completion of twenty-five years' service as Secretary to the Society of Arts and Sciences. Those who have come into personal contact with Mr. Foster—and many of our readers have doubtless been in communication with him when reading papers or taking part in the discussions at that Institution—will appreciate the motive which has prompted the initiation of this fund.

* * *

One of those curiosities in literature for which quack doctors are famous came into our hands the other day in the shape of a pamphlet entitled "Phosphorine: a Lecture delivered at St. James's Hall by Dr. Sutton. 147th edition. See Testimonial from Sir William Stokes, M.D." Of course, we do not intend noticing this production otherwise than for the purpose of drawing the attention of one of those commendable associations which have done so much to rid the profession of

these impostors. This *soi-disant* author is not a qualified medical man; his so-called lecture was not delivered at the St. James Hall; no such member of the medical profession has lived in the present century as Sir Wm. Stokes to give him a testimonial; and the 147th edition is a myth, except probably each copy constitutes an edition. Here is a man advertising freely in the lay press with no other purpose than to deceive the public by the use of such honoured names as Drs. Stokes and Sutton—a man we have no hesitation in denouncing as an impostor.

* * *

Our Cousins on the other side the Atlantic are generally accredited with the facility of "drawing the long bow." To give an instance: we were once talking with an American among other matters about trains, comparing our own rapidity of transit with that we had experienced in America. Our friend replied that the Americans travelled so much faster, that the telegraph posts on the side of the line appeared to the passenger to be no further apart than the teeth in a comb. In the June number of the *Buffalo Medical Journal*, we notice a review of Leonard's "Vest Pocket Anatomist," in which the writer winds up by saying "50,000 copies have been ordered by a London firm for use in England." Thinking this a *slight* exaggeration, we took the trouble to inquire, and we find that Messrs. Baillière, Tindall, and Cox is the firm referred to, and the number ordered 1,500. We feel sure the editor of the *Buffalo Medical Journal* will pardon our calling his attention to this *little* error; 50,000 would be nearly sufficient to supply every medical man and medical student in the United Kingdom with three copies a piece.

Medico-Parliamentary

PUBLIC HEALTH AMENDMENT BILL.

In the House of Lords, on Friday last, the report on the Public Health Act (1875) Amendment Bill was brought up and agreed to.

Earl Delaware intimated his intention of taking the opinion of the House upon the Bill when it came on for third reading.

FORCIBLE CONFINEMENT OF AN IMBECILE.

In the House of Commons, on Friday last, Mr. Sclater-Booth said, in answer to Mr. A. Brown, that Eliza Littlehales, a pauper receiving out-door relief in the Madeley Union, was an imbecile in charge of her sister. The chairman of the guardians, finding that she was inadequately cared for, in his capacity as a magistrate ordered her removal to the workhouse with the view to her removal to the asylum. She was so removed, and the good food and treatment which she had received in the asylum had materially improved her health, and she was now again under the care of her sister. He admitted that the circumstances of her removal to the workhouse were illegal, but the medical officer was prepared to certify that her immediate removal was at the time necessary.

CONTAGIOUS DISEASES (ANIMALS) ACT.

In the House of Commons on Monday Sir H. Selwin-Ibbetson moved the second reading of this Bill, which had passed the Lords, explaining the necessity for the measure by the fact the diseases which it was designed to stamp out were imported from abroad. that their existence in this country had occasioned considerable loss, and that the present restrictions were insufficient to prevent their spread. That the diseases could be stamped out there was ample evidence to prove; but it was not to be effected by inspection at the port of landing, for inspection had failed, and slaughter at the port of landing appeared to be the only alternative, and for that alternative the Bill provided.

Mr. Forster moved, as an amendment, that the slaughter at the ports of landing of all fat cattle from the Continent would increase the cost of food, and should therefore not be made compulsory under all circumstances by Act of Parliament.

There was a long debate, which was adjourned.

PUBLIC HEALTH (IRELAND) BILL.

This Bill was read a third time and passed on Monday.

PUBLIC HEALTH (ENGLAND) AMENDMENT ACT.

This Bill stands for third reading in the House of Lords to-night, when the Earl of Delawarr will move its rejection.

Medical News.

Queen's University in Ireland.—At a meeting of the University held on Monday, June 17, the following degrees and diplomas in the faculty of Medicine were conferred:—

Doctor of Medicine.—Charles Warke Allison, B.A., of Queen's College, Belfast; Alfred Constantine Bennett, of Queen's College, Cork; John Thomas Collier, of Queen's College, Belfast; Patrick Oswald Considine, of Queen's College, Belfast; William Fleck, of Queen's College, Belfast; Robert Evans Hadden, of Queen's College, Cork; Charles Hall, of Queen's College, Belfast; J. Courtney Haslett, of Queen's College, Belfast; Francis Thomas Heuston, of Queen's College, Galway; Charles Kevin, of Queen's College, Belfast; Pershouse Wm. L. Langley, of Queen's College, Belfast; Joshua Lytle, of Queen's College, Belfast; Daniel Roderick O'Connor, of Queen's College, Cork; James Wigmore, of Queen's College, Cork.

Master in Surgery.—Patrick Maurice Corleton, M.D., of Queen's College, Belfast; Isaac C. Dundee, M.D., of Queen's College, Galway; Alfred C. Bennett, of Queen's College, Cork; William Fleck, of Queen's College, Belfast; Robert Evans Hadden, of Queen's College, Cork; Francis Thomas Heuston, of Queen's College, Galway; Charles Kevin, of Queen's College, Belfast; Pershouse Wm. L. Langley, of Queen's College, Belfast; Joshua Lytle, of Queen's College, Belfast; Daniel Roderick O'Connor, of Queen's College, Cork.

Diploma in Midwifery.—Alfred C. Bennett, of Queen's College, Cork; John Thomas Collier, of Queen's College, Belfast; Robert Evans Hadden, of Queen's College, Cork; Charles Kevin, of Queen's College, Belfast.

J. Fritz Beck, M.A., M.D., of Queen's College, Belfast, *in absentiâ*.

Hydrophobia.—On Sunday last a horrible death from hydrophobia occurred in Paris. About a fortnight ago M. Cheri Montigny, a young man of two and twenty, the only son of the manager of the Gymnase Theatre, was slightly bitten by a favourite bull-terrier, and not suspecting any harm, took no notice of it. The dog was subsequently sent to a veterinary surgeon, and died from some internal complaint, not hydrophobia, and the unfortunate youth, dining with some friends last Wednesday, actually congratulated himself on not having alarmed his father. Two days ago the symptoms of hydrophobia set in, and the patient had the strength of mind to request a strait waistcoat to be put upon him, and he died in fearful agony.

The Anti-Vivisectionists.—The second anniversary meeting of the International Association for the Total Suppression of Vivisection, was held on Friday last, at Willis's Rooms, the Rev. Canon Baynes, M.A., of Coventry, presiding. He was supported on the platform by several medical men and clergymen, but three-fourths of the audience were ladies. The report, which was taken as read, stated that the association kept steadily in view that unfaltering allegiance to the principle of total suppression, to be brought about by Mr. Holt's Bill. The object of the association was to promote total suppression by law, and to resist the practices of vivisection, as well for its debasing moral influence on those who perpetuated it, as because it was in itself a direct offence against the merciful Creator and the defenceless creatures which He had made. Dr. Scott moved, and the Rev. H. N. Oxenham, M.A., seconded the first resolution, "That the practice of vivisection is condemned alike by the absence of any proof of its medical value, and by the essentially immoral nature of the principle on which alone it can be maintained." The resolution was adopted unanimously. A second resolution re-

cording the gratitude of the meeting to Mr. Holt for again introducing his Bill to put down vivisection, was also agreed to.

Can Strychnine Spasm be confined to the Heart and Respiratory Muscles?

THE body of a woman has recently been disinterred at Crewe, on an order from the coroner, it having transpired that there was reason to believe her death had not arisen from the cause set down in the burial certificate. It appeared that her husband on returning from his work, found his wife in great agony, suffering from spasms at the heart. A medical man was called in, but on his arrival the woman was breathing her last. She had occasionally suffered from similar spasms. Mr. J. P. Brumwell, surgeon, of Keswick, said that when he saw the woman her lips were livid, and her face in a cold, clammy sweat. The action of the heart was intermittent and laboured [illegible] there was spasm of the intercostal muscles, and [illegible] the diaphragm, but there was no tetanic spasm of the muscles of the limbs whatever. He gave a certificate—*angina pectoris*. On making the *post-mortem* examination, however, he found evidence of strychnine in the stomach, such as left no doubt whatever in his mind as to the real cause of death. Had there been spasm of the limbs he might have suspected strychnine, but there was not. It was proved that deceased had purchased two-pennyworth of a vermin-killer, whose principal ingredient was strychnine, the day before her death, and the jury returned a verdict that deceased had died from the effects of strychnine, administered by herself.

NOTICES TO CORRESPONDENTS.

☞ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

READING CASES.—Cloth board cases, gilt-lettered, containing 26 strings for holding each volume of the MEDICAL PRESS AND CIRCULAR, can now be had at either office of this Journal, price 2s. 6d. The postal regulations not allowing the Journal to be stitched, these cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

NOTICE TO SUBSCRIBERS.—Subscribers who have not already paid their subscriptions for last year are reminded that they are now due and should be sent to the publishers, who will be happy to acknowledge their receipt.

HYDROPHOBIA IN LANCASHIRE.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—Inasmuch as that in one of your special articles last week headed "Hydrophobia in Lancashire," you assert that the authenticity of my case has been disputed, I should like to point out that it is only last week that the *Lancet* published an account thereof, and that no other contribution to any paper has been sent by me, or any person in connection with the case. I am not answerable for any reports that may have appeared without my knowledge or sanction in the lay papers, and I am obliged to ignore *their* publications as being neither authorised or correct.

Faithfully yours,

Chelmsford, June 20. JAMES NICHOLLS, M.D, F.R.C.S.

[If Dr. Nicholls will consult our Report he will find his name mentioned. We heard, previous to the publication of Dr. Nicholl's case in the *Lancet*, some doubts expressed in well-informed professional circles, as to the correctness of the diagnosis by Dr. Nicholls, and we believe it was based on a letter of his own. We did not express an opinion, as, in the first place, we had not sufficient evidence, and in the second, we were inclined to credit Dr. Nicholl's statement. Did Drs. Burdon Sanderson, Brunton, or Callender agree with the diagnosis? In Saturday's *Lancet* Dr. Nicholl's will find an anonymous communication referring to his case.—ED. M. P. & C.]

SANITARY INSTITUTE OF GREAT BRITAIN.—The Anniversary Meeting of this Association will be held this day (Wednesday) at the Royal Institution at 4 p.m. A *conversazione* will be held at 8 p.m. at t Grosvenor Gallery.

PHYSIOLOGIST.—You will find the Silber burner answer your purpo best for laboratory purposes. The flame is exceedingly steady and t light as white as you could desire. We have had one in use for so time past, and have practically tested it. We have not tried it for d tillations, as we use a large Bunsen burner for this purpose, but t large batwing Silber burner would probably answer equally well.

ARTIFICIAL PALATES.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—Can you kindly inform me of the name and address of t inventor of artificial gutta-percha palates?

Yours faithfully,

Bampton, Devon. A. H. RENDELL.

[An account and diagram of the Obturator devised by Mr. Norton i to be found in the issue of the MEDICAL PRESS AND CIRCULAR of th 19th April, 1876 (page 321). The instrument was manufactured b Mr. Sewill. Any dental surgeon could make such an obturator, whi it must be understood, is applicable only in cases where the uvula an soft palate are united, though a slight modification would fit it for oth conditions, and in manufacture care must be taken not to have th body which unites the flexible rim to the mould of the roof of th mouth too tightly fitting the aperture, otherwise muscular contractio ll cause the palate to ache and render the instrument unbearabl The flexible rim is of course rather larger than the aperture betwee the nose and mouth, so that whilst the instrument is being inserte the rim is bent, but when in position the rim, returning to its natura position, lies on the upper surface of both the hard and soft palates an relaxes the instrument *in situ*.—ED. M. P. & C.]
